[0035] (1) an antenna/waveguide that is geometrically optimized having a conducting surface; and

[0036] (2) a primary (apex) coil wound with an insulated conductor over a non-conductive coil form, the coil being connected to an AC or AC-DC driver at its bottom lead and, by its top lead to the conducting surface of the antenna/waveguide near the point where the electric field contacts the antenna/waveguide, and the antenna/waveguide serving as a quasi-capacitive series element to provide a specific resonant frequency; and

[0037] (3) a secondary coil of smaller diameter than the primary (apex) coil having a greater number of turns than the primary coil, the secondary coil being positioned coaxially within the primary coil and acting as a resonant step-up transformer winding inductively coupled with the apex coil;

wherein the generator absorbs impulses from Earth's electric oscillations; and

wherein the attracted energy manifests as high voltage sinusoidal waveforms in the secondary coil, representing harvested electrical energy of atomic oscillators and measurable on the leads of the secondary coil.

[0038] In this embodiment, more than one resonant step-up transformer winding can be used. As described above for the first embodiment, in this embodiment, the electric generator stimulates and attracts the electric emissions of atomic oscillators by the use of high voltage. Typically, in this embodiment, the antenna/waveguide is designed based on functions of phi and/or pi. In one alternative, in this embodiment, the antenna/waveguide is placed on an insulated base. Typically, in this embodiment, the generator further comprises an insulating base on which the antenna/waveguide is placed. Typically, in this embodiment, antenna/waveguide is at a high voltage during the operation of the generator. Typically, in this embodiment, the antenna/waveguide voltage is measured by using an E-field antenna. In this embodiment, the antenna/waveguide can be connected to an oscillator. The oscillator can be a resonant step-up transformer. Preferably, in this embodiment, the antenna/waveguide is of pyramidal shape. Preferably, in this embodiment, the antenna/waveguide exhibits functions of phi and/or pi. Typically, in this embodiment, the antenna/waveguide is positioned in the general North-South direction. In this embodiment, in this arrangement, when the antenna/waveguide is of pyramidal shape, the height of the pyramid can vary from about 0.1 m to about 1000 m. The optimal pyramid size is a function of the power requirements. However, a pyramid can be built as high as 1 km in height. In this embodiment, the base surface area of the pyramid may range from about 0.01 m^2 to about 1,000,000 m^2.

[0039] In this embodiment, typically, the primary (apex) coil of the resonant transformer is connected near the point where the electric field contacts the antenna/waveguide.

[0040] In this embodiment, typically, the bottom lead of the secondary coil is connected to ground. In this embodiment, typically, the primary (apex) coil is inductively coupled to the secondary coil.

[0041] In this embodiment, typically, the output of the secondary coil is connected to a load for drawing power from the generator.

[0042] Another embodiment of the present invention is an electric generator for harvesting the electric emissions of atomic oscillations comprising an oscillator.

[0043] In this embodiment, typically, the oscillator operates in the LF or ELF bands.

[0044] Typically, in this embodiment, the electric generator comprises:

[0045] (1) a primary (apex) coil wound with a conductor over a secondary coil, the primary (apex) coil being connected electrically at its bottom lead to a driver operating in the LF or ELF bands while connected by its top lead near the point at which the electric field contacts the conductive surface of the antenna/waveguide; and

[0046] (2) a secondary coil of smaller diameter than the primary coil having a greater number of turns than the primary coil, the secondary coil being positioned coaxially within the first coil and acting as a resonant step-up transformer winding inductively coupled with the primary;

wherein said resonant step-up transformer's output voltage exceeds 500 V_{RMS};

wherein the electric generator attracts impulses from Earth's electric oscillations;

and wherein the attracted energy manifests as high voltage sinusoidal waveforms representing harvested electric energy of atomic oscillations in the secondary coil.

[0047] In this embodiment, typically, the output of the secondary coil is connected to a load for drawing power from the generator.

[0048] Another aspect of the invention is a method of tapping Earth's electric energy based on the following concepts:

[0049] (1) utilizing a pyramidal antenna/waveguide designed based on the functions of phi and/or pi;

[0050] (2) using the antenna/waveguide to absorb and focus specific frequencies of Earth's electric field;

[0051] (3) positioning a coil(s) connected to the pyramidal antenna/waveguide near or at its apex according to the present invention; and

[0052] (4) generating a high-voltage sinusoidal signal, representing harvested atmospheric and telluric electrical energy, by the operation of the system.

[0053] Typically, the harvested electric energy can be fed into a power grid for distribution, but smaller units capable of distributed power generation or for use as stand-alone generators are also feasible by the concept of this invention.

[0054] In this aspect, the method typically comprises a method of tapping Earth's electric oscillatory energies comprising the steps of:

[0055] (1) positioning an electric generator according to the present invention as described above such that it is exposed to Earth's electric oscillations; and

[0056] (2) generating a sinusoidal voltage signal representing harvested electric energy of atomic oscillators by the operation of the generator.

[0057] The invention is described by the following Example. This Example is included for illustrative purposes only and is not intended to limit the invention.

Example

[0058] We have introduced a new theory of space, energy and matter that predicted that electromagnetic interaction propagates through a carrier medium called the space lattice that is made up of pulsating, phi-based spiral vortices (STAR), the excitation of which generates propagating sinusoidal lines of force across the space lattice recorded as electromagnetic waves by our instruments [1,2]. We have also predicted that natural pressure gradients exist within the space lattice that can be used for power generation by inserting a capacitor into such gradient. Furthermore, we proposed that a pyramid-shaped capacitor is an optimally shaped device for tapping the energy gradient of the space lattice that manifests in the form of an electrical potential gradient in Earth's atmosphere. This was subsequently demonstrated [3-5]. We also found that the pyramid-shaped capacitor design should be based on functions of phi and/or pi [5] because electrical energy propagates along a phi-based spiral [6].

[0059] We suggested that elemental particles are composed of STAR oscillators that make up the space lattice by electromagnetic compression of its elemental cubes into pulsating conical/vortexual subunits that form the basis for all particles of matter [1,2]. We proposed that atomic and subatomic oscillators could vibrate in a very wide frequency range from sub-acoustic to extremely high EM frequencies [1,2]. This does not mean that material bodies can take or maintain a physical form at any energy level, but this allows the recycling of atoms into the space lattice as part of their natural evolution [2,6].

[0060] Atomic oscillators are constantly in motion, and such motion is electric because all motion and energy is fundamentally electric [2,6]. It is known that atomic bodies constantly exchange electric energy. Such energy flow can be harvested when the spiral physical nature of electric waves is recognized. Russell observed that energy moves during its generative cycle in spirals towards the higher potential [7]; therefore, we reasoned that an "attractor" of high electric potential must be provided to pull in the random electromagnetic emissions of atomic oscillators. The "attractor" must function as a phi-based antenna/waveguide to focus the phi-based electric emissions of atomic bodies into the apex of a vortex, the same method Nature uses for power multiplication [6,7]. Therefore, a phi-based pyramidal antenna/waveguide must be at a high voltage in order to perform its attractor function.

[0061] To achieve this goal, a geometrically optimized pyramidal antenna/waveguide must be connected to an oscillator that operates at a high voltage and is tuned to a suitably selected frequency.

[0062] The appropriate resonant frequency is dictated by practical considerations. Atomic oscillators can vibrate in a very wide frequency range [1, 2, 7, 8] but short wavelength radiations are readily re-absorbed by atoms and are rapidly attenuated; therefore, long wavelength electromagnetic emissions should be targeted. The operation of the pyramid generator is most practical in the ELF to the LF range. As electric radiation propagates in a vortex [2,7,8], the emitted electric vortex over the pyramidal antenna (FIG. **1**) increases its "size," and so it is capable of funneling atmospheric electromagnetic emissions of the same frequency back into the antenna/receiver. Thus, the pyramid electric generator could capture the energy emitted by both telluric and atmospheric atomic oscillators. We have tested these assumptions and demonstrated the basic principles of an electric generator.

Methods and Results

[0063] In our previous paper, we reported on a pyramid-shaped capacitor/antenna connected in series to a coil that form a resonant circuit for harvesting an expanded range of atmospheric and telluric electric energies [6]. As the signals in the pyramid energy harvester system are at extremely high voltages, we have developed a measurement and control system that allows secure remote transmission of test signals with great accuracy while removing all the hazards associated with direct connection of ultra-high voltages (over 50 kV AC) to the measurement and data-logging system. The voltage and current signals measured across a resistor are turned into a proportional electronic signal, which is then fed to a light emitting diode (opto transmitter) and sent through an optical cable to the instrumentation part of the system where it is converted back by an opto receiver module into an electronic signal for acquisition and processing by the National Instrument PXI 1042Q controller programmed with Labview 6. An ENI-1140LA amplifier was used to activate the oscillator at the resonant frequency.

[0064] For the experiments, we used a novel tetrahedral pyramid-shaped antenna/waveguide that expressed the golden mean in its ratios. The base length of the pyramidal antenna was 6.26 feet. The pyramid was built of a wooden frame and covered with 26 AWG triangular copper sheets on its sides that were electrically connected. It was placed on an insulating base and positioned in the general North-South direction.

[0065] The apex coil was wound on a HDPE cylindrical coil form using a 14 AWG insulated magnet wire with a monofilament spacer polyester twine (0.05" diameter) between the turns, and connected to the conducting surface of the pyramid near its apex. Thus, the apex coil is connected to the pyramidal antenna/waveguide acting as a quasi-capacitive series element to provide a specific resonant frequency by coupling to the ambient electromagnetic environment. The bottom lead of the apex coil was connected to a driver and grounded via the driver (FIG. **2**). The purpose of the monofilament spacer is to reduce interwinding capacitance in the apex coil by increasing distance between wire turns of the coil.

[0066] The parameters of the apex coil are shown in Table 1.

TABLE 1

Physical and electrical parameters of the apex coil

Number of turns of wire	290	
Coil height	0.87	m
Coil diameter	0.787	m
Wire diameter	1.6277	mm
Inductance	42.86	mH
Resistance	6.5	ohms

[0067] In the experiment, the controlled variable was the voltage, which was increased in steps by the controller until a maximum voltage in the system (permitted by circuit components and test equipment) was achieved for the given resonant frequency. The objective was to "drive the atmosphere and ground" by radiating a high voltage (~200 kV p-p), LF (~70 kHz) signal fed by a powerful signal generator at a resonant frequency determined by the pyramid as a quasi-capacitive series element connected to the apex coil and radiating to the local atmosphere and the ground.

[0068] The experimental data are shown in Table 2. An apparent power gain of nearly 170-fold was achieved in the resonant circuit relative to input power from the driver.

TABLE 2

Power measurements in the resonant pyramid-coil system.

Frequency (kHz)	Drive voltage (rms)	Drive current (rms)	Drive power (VA)	Drive power (W)
70.9	321.1 V	3.2 A	1125.54	735.5
Frequency (kHz)	Apex voltage (rms)	Apex current (rms)	Apex power (kVA)	Apex power (kW)
70.9	67.922 kV	2.903 A	196.621	40.393

[0069] A load may be connected to the system to draw power from it. The load may also be connected via a secondary coil inductively coupled to the apex coil. The load may be a resistor, a rectifier or storage capacitor powering a DC load. The high voltage, high frequency output can also be converted to the frequency and voltage of standard mains power.

[0070] A graphic representation of the system is shown in FIG. **2**. The pyramidal antenna/waveguide, placed on an insulating base, is coupled to the ambient electromagnetic environment and serves as an antenna/waveguide for the harvesting of atmospheric and telluric electromagnetic oscillations at resonance frequency (FIG. **1**). The atmospheric electric vortex possibly acts as an ionic antenna pulling in EM radiations from a large atmospheric domain.

[0071] The pyramid's apex is connected to a coil of high turn number (FIG. **2**). This apex coil wound on a nonconductive coil form forms a resonant circuit with the pyramid that acts as a quasi-capacitive series element. An RF power amplifier activates the apex coil. The measurement points are also indicated, displaying the positions of voltage and current sense resistors and opto-electric transmitters. A detailed description of the system follows in FIG. **2**.

[0072] The source of radiative and electromagnetic power to earth is the Sun **1**, which is harvested by effect of pyramid operations. Solar radiation is separated into light, heat, electromagnetic waves **2** by interaction with atmosphere, magnetosphere, ionosphere. "Electrosphere" **3** comprises of ionized, highly conductive air. It can be understood as a conductive spherical band about 60 mi above the surface of the earth. Virtual "Ground" **4** in electrosphere—a low impedance spherical area that in the circuit may be considered as a "ground" (for non-harvesting calculations) or a variable circuit source (for harvesting calculations). Effective resistive impedance **5** is from pyramid surface to "sky" or "electrosphere" (radiative impedance). Effective capacitive impedance **6** is from pyramid surface to "sky" or "electrosphere". Effective resistive (conductive) impedance **7** is from pyramid external surface to nearby atmosphere due to "corona" type ionic conduction through ionized air, caused by high peak voltages on the pyramid's surface. Conductive pyramidal transducer/energy harvester **8** is coupled to the ambient electromagnetic environment as above. Radiated "near field" electromagnetic field **9** from pyramid surface (toward "sky") is measured by E-field antenna **10**. The antenna does indirect measurement of pyramid surface voltage based on E-field pick-up of alternating current field within ~20 ft of pyramid surface, at a particular fixed distance and orientation. Impedance-matching resistor **11** couples E-field antenna to coaxial cable and impedance-matching capacitor **12** for coupling E-field antenna to coaxial cable. Coaxial cable **13** connects to measurement system interface with a "BNC" connector **14** to provide electrical interface to measurement system. System "ground" (common connection point) **15** is for measurement/control system components. Switch **16** is for disconnection of pyramid/antenna from pyramid driving electronics. Radiative "cone" **17** emits from inside and bottom surface of pyramid towards "ground" underneath the pyramid harvester system. Radiated E-M field **18** is directed from pyramid to ground surface directly underneath. Resistive impedance **19** of radiated E-M field ("virtual" component) is derived from measurement and calculation of E-M field model to ground area. Capacitive impedance **20** of radiated E-M field to "ground" area is a "virtual component" derived from measurement and calculation of E-M field model. Virtual resistance of radiated energy **21** from bottom of pyramid, is conducted through earth to "firm ground" potential (another "virtual component" derived from measurement and calculation). Pyramid ground **52** is an equipotential "zero-impedance" point in the earth which serves as the ground reference for both conducted (from pyramid ground stake **52**) and radiated **18**, **19**, **20**, **21** energy underneath the pyramid harvester device. In a non-harvesting model this ground point is always at zero potential. However, in an energy-harvesting model the point **22** serves as an AC voltage source, sending conducted energy back into the pyramid system through all the components that "drain" to it in the non-harvesting model. Sense resistor **23** for apex current monitor in pyramid energizing system is a low value resistor (typically 0.05 to 0.2 ohms) that allows a small voltage to develop, proportional to the current flowing to the pyramid apex from the energizing system. Apex current monitor opto transmitter **24** measures the voltage across resistor **23** and turns it into a proportional electronic signal, which is then fed to a light emitting diode and transmitted through an optical cable to the instrumentation part of the system. All the signals in the pyramid harvester system are at extremely high voltages, and the optical cable allows secure remote transmission of these signals to the measurement and data-logging system (not shown on this diagram). Resistance **25** of the apex excitation coil **26** is measured at DC. This is a "virtual" component, since the resistance is in the coil itself, and is not a separate component. Apex coil **26** translates the stimulation power signal from amplifiers **34**, **35** into a very high voltage at the resonant frequency established by the coil and intrinsic capacitance of the pyramid. Mutual inductance coupling exists between the apex coil and the harvest or secondary coil **27**. This is another "virtual component" consisting of the electromagnetic signal coupling between the two coils based on many different factors. Optional resistor **28** can be used for resonance or phase tuning of pyramid network. The main resonance is determined by apex coil **26** inductance and pyramid lumped capacitive element **8**. However, this will make the voltage at the junction of the pyramid (capacitor) and the apex coil **26** approximately 90 degrees out of phase with the current. One approach to reduce the phase angle and also to possibly tune the resonant frequency and the Q of the circuit is to insert an additional reactive element **29** in parallel into the apex coil **26**. The apex coil winding resistance is expressed here as resistor **25** in series with inductor **26**. The inserted element is an additional optional capacitor **29** in parallel with the apex coil. This capacitor develops an independent L-C resonant circuit, besides the L-C resonant circuit of the apex coil and pyramid. An anticipated function if used in the circuit would be to lower the resonant frequency. Drive current monitor current sense resistor **30** is for drive current opto transmitter **31**. Summing/protection resistors are placed in series with **32** drive **1** and **33** drive **2**. Power amplifiers **34**, **35** drive coil/pyramid resonant system. Power (drive) amplifier signal input **36** is fed through opto receiver **37**. The signal in the optical cable **38** is from the National Instruments control system for control of power amplifiers. Pyramid system ground (star-ground) connects to top of pyramid ground stake, after ground stake disconnect switches **39** and **50**. Power supply **40** is for pyramid driver amplifier. Resistor **41** is used for voltage measurement across power driver higher value terminals. Opto transmitter **42** is for voltage measurement across power amplifier and includes drawing of optical cable to measurement system. Current-sensing resistor **43** is for current measurement from pyramid amplifiers to ground post. Opto transmitter **44** is for transmitting ground current to control and measurement system. Voltage sense resistor **45** is between pyramid ground stake **52** and remote ground stake **55** (100 kohm-1 Mohm). Opto transmitter **46** is for voltage sense from pyramid ground **52** to remote ground **55**. Current sense resistor **47** from pyramid ground to remote ground is for opto transmitter **48**. When used, this closes switch **49**B to short out the voltage measurement **45** and also short out the intrinsic ground impedance **58** between pyramid ground and remote ground stakes. Ground post disconnect switch **49** is below the system star ground stake and is very dangerous when open. Main connection point for pyramid system is the star ground terminal **50**. Ground surface **51** is on which pyramid system is placed. Ground stake **52** for pyramid system is a 1" diameter copper rod, 8-12 ft deep. R absolute **53** is between ground stake and earth integrated from ground stake theoretically through entire earth. "Absolute ground" is located under pyramid and ground stake **54**. Remote ground stake **55** is about 200 feet away from pyramid system and is used as remote reference ground although a real remote ground would likely be much further away. R absolute **56** is from remote ground stake to absolute ground under remote stakes **57**. Ground impedance **58** between **52** and **55** stakes appears mostly resistive and is about 28-30 ohms based on AC measurements at 1 KHz. The remote ground setup is not required for the operation of the system but provides test data. Harvest/secondary coil **59** is an inductor wound with 3 to 6 times as many turns as the apex coil, and connected to it by mutual inductance **27**. Current sense resistor **60** is placed on top lead of harvest coil. Opto transmitter **61** is for top harvest coil current. Voltage sense resistor **62** that measures voltage across harvest coil is for opto transmitter **63**. Load resistor **64** is for secondary/harvest coil and the load resistor is optimized to draw the maximum power from the harvest/secondary coil such that the energy harvest efficiency of the entire system is optimized. This is the defining element of the system. Voltage sense resistor **65** for the opto transmitter for load voltage **66** measures the voltage across the load. Current sense resistor **67** is placed at bottom side of harvest coil. Opto transmitter **68** is for bottom lead current sense resistor **67**. A jumper is placed to system ground **69** that allows grounded operation of the harvest coil with system ground **70**. More than one step-up transformer coil can be used as energy harvester in the pyramid generator system.

[0073] The minimum system is shown in FIG. **3**. When a minimum system is used, a load can be directly connected to the pyramid's surface.

DISCUSSION

[0074] This invention demonstrates a novel approach to harvest Earth's electric energy. The masses of Earth and its atmosphere represent a coupled resonant system that is continually electrified by solar radiation. We have found that a pyramidal antenna designed based on the functions of phi and/or pi is optimal for the capture of atmospheric electrostatic discharge (ESD) impulses [3-5]. Atmospheric ESD is a product of solar radiation and is a wide bandwidth phenomenon. The pyramid as a wideband, non-resonant antenna is uniquely adapted to harvest the energy of atmospheric ESD.

[0075] This invention also points out an additional energizing mechanism at work during the operation of the pyramid electric generator. The observation is derived from our theory on energy, matter and space [1,2] as well as that of Russell [7]. Both Russell and we observed that spiral motion is a fundamental action of matter and that the vortex is the mechanism of power multiplication in Nature. A vortex concentrates power into its apex where the highest velocity of motion, the highest pressure and the highest electric potential resides [1, 2, 6, 7]. As electricity propagates along a pulsating phi-based spiral [6,7], a phi-based antenna/waveguide is suitable to focus its energy into the apex of a vortex inside the antenna. A phi-based pyramid is optimal for this purpose.

[0076] As atomic bodies can oscillate in a very wide frequency range [1, 2, 7, 8], a pyramidal antenna/waveguide coupled to an oscillator that is tuned to a suitable frequency can focus the "electric noise" from Earth's atomic oscillators into the apex of the pyramid at a high voltage. Russell observed that energy moves towards the higher potential during its generative cycle [7]; therefore, it is essential that the pyramidal antenna be at a high potential. Our results corroborated this assumption.

[0077] For practical reasons on our small pyramid, we have chosen a frequency above the audio range but below the radio frequency spectrum; our antenna was made to emit at the target wavelength. The wavelength of the 50-120 kHz range is 6 km to 25 km, thus allowing energy to be harvested over a large atmospheric domain. As electrical energy propagates in a vortex [6,7], the emitted electric vortex (ionic antenna) over the pyramidal antenna/waveguide increases its "size" and enables it to funnel the same frequency atmospheric electromagnetic radiations back into the antenna. Thus, the pyramid electric generator captures at the selected frequency the energy emitted by Earth's atomic oscillators.

[0078] The presence of an electric (ionic) vortex was demonstrated by radar testing of the space over a 44 m tall fiberglass pyramid located near Moscow [12]. The Russians found that the large ionized column of air over the area of the vertical axis of the pyramid had a width of about 500 m and reached an altitude of 2 km. It is remarkable that this effect was induced by a nonconductive pyramid surface and demonstrating a significant degree of atmospheric ionization even under fair weather conditions. Thus, a suitably sized large or an electrically activated small pyramid should open a low impedance path to higher elevations of relatively conductive atmospheric domains.

[0079] In conclusion, the total power that can be extracted from Earth's atomic oscillators must be extremely large, likely far exceeding current global electric generation capacity. In our experiment, we measured over 196 kVA power at the pyramid's apex at about 200 kV p-p voltage using a 6.26 feet base length pyramid. This power is 175 times greater than the power necessary to drive the pyramid to this operating voltage. By constructing the pyramid generator from appropriate high voltage components and using higher drive voltages, a significant increase in power output is envisioned. The power extraction will also be enhanced by further optimization of the designs of both the pyramid and the coil system.

[0080] The power output will also increase by employing larger pyramid structures and coils. As voltage is the primary factor in attracting power into the system, the necessary voltage can be provided by the vertical atmospheric potential on a tall pyramid. Since the atmospheric vertical potential gradient could go as high as 1200 V/m near Earth's surface under fair weather conditions [13], a pyramid height of 20-150 m seems sufficient to provide the apex voltage for a self-sustaining power generator. As the pyramid scales up volumetrically, a power generator pyramid of the size range of the GPG could likely have an output in the range of hundreds of gigawatts. Groups of several pyramid electric generators could be placed within specific geographical areas, thus combining their energy harvesting capacity.

ADVANTAGES OF THE INVENTION

[0095] The present invention provides a new method of tapping Earth's electric energy pool and providing usable power that can be fed into the power grid or supplied by stand-alone power generators. It does so without the need for mechanical energy or the consumption of fossil fuel or the long-term risks associated with power generated by nuclear fission, including the risk of diversion of fissionable material to terrorist aims or the risk posed by the required long-term storage of spent nuclear fuel. Devices according to the present invention can operate virtually continuously with little to no maintenance.

[0096] Articles of manufacture and methods according to the present invention possess industrial applicability for the generation, storage, and transmission of electrical energy.

[0097] With respect to ranges of values, the invention encompasses each intervening value between the upper and lower limits of the range to at least a tenth of the lower limit's unit, unless the context clearly indicates otherwise. Moreover, the invention encompasses any other stated intervening values and ranges including either or both of the upper and lower limits of the range, unless specifically excluded from the stated range.

[0098] Unless defined otherwise, the meanings of all technical and scientific terms used herein are those commonly understood by one of ordinary skill in the art to which this invention belongs. One of ordinary skill in the art will also appreciate that any methods and materials similar or equivalent to those described herein can also be used to practice or test this invention.

[0099] The publications and patents discussed herein are provided solely for their disclosure prior to the filing date of the present application. Nothing herein is to be construed as an admission that the present invention is not entitled to antedate such publication by virtue of prior invention. Further the dates of publication provided may be different from the actual publication dates which may need to be independently confirmed.

[0100] All the publications cited are incorporated herein by reference in their entireties, including all published patents, patent applications, literature references, as well as those publications that have been incorporated in those published documents. However, to the extent that any publication incorporated herein by reference refers to information to be published, applicants do not admit that any such information published after the filing date of this application to be prior art.

[0101] As used in this specification and in the appended claims, the singular forms include the plural forms. For example the terms "a," "an," and "the" include plural references unless the content clearly dictates otherwise. Additionally, the term "at least" preceding a series of elements is to be understood as referring to every element in the series. The inventions illustratively described herein can suitably be practiced in the absence of any element or elements, limitation or limitations, not specifically disclosed herein. Thus, for example, the terms "comprising," "including," "containing," etc. shall be read expansively and without limitation. Additionally, the terms and expressions employed herein have been used as terms of description and not of limitation, and there is no intention in the use of such terms and expressions of excluding any equivalents of the future shown and described or any portion thereof, and it is recognized that various modifications are possible within the scope of the invention claimed. Thus, it should be understood that although the present invention has been specifically disclosed by preferred embodiments and optional features, modification and variation of the inventions herein disclosed can be resorted by those skilled in the art, and that such modifications and variations are considered to be within the scope of the inventions disclosed herein. The inventions have been described broadly and generically herein. Each of the narrower species and subgeneric groupings falling within the scope of the generic disclosure also form part of these inventions. This includes the generic description of each invention with a proviso or negative limitation removing any subject matter from the genus, regardless of whether or not the excised materials specifically resided therein. In addition, where features or aspects of an invention are described in terms of the Markush group, those schooled in the art will recognize that the invention is also thereby described in terms of any individual member or subgroup of members of the Markush group. It is also to be understood that the above description is intended to be illustrative and not restrictive. Many embodiments will be apparent to those of in the art upon reviewing the above description. The scope of the invention should therefore, be determined not with reference to the above description, but should instead be determined with reference to the appended claims, along with the full scope of equivalents to which such claims are entitled. Those skilled in the art will recognize, or will be able to ascertain using no more than routine experimentation, many equivalents to the specific embodiments of the invention described. Such equivalents are intended to be encompassed by the following claims.

I claim:

1. An electric generator for harvesting the energies of atomic oscillators comprising:

(a) an antenna/waveguide that is geometrically optimized having a conducting surface; and

(b) a coil wound with an insulated conductor over a non-conductive coil form, the coil being connected to an AC or AC-DC driver at its bottom lead and, to the conducting surface of the antenna/waveguide by its top lead near the point where the electric field contacts the antenna/waveguide, with the antenna/waveguide serving as a quasi-capacitive series element to provide a specific resonant frequency;

wherein the generator absorbs impulses from Earth's electric oscillations; and

wherein the attracted energy manifests as high voltage sinusoidal waveforms in the coil, representing harvested electrical energy of atomic oscillators and measurable on the leads of the coil.

2. The electric generator of claim **1**, wherein the electric generator stimulates and attracts the electric emissions of atomic oscillators by the use of high voltage.

3. The electric generator of claim **1**, wherein the antenna/waveguide is designed based on functions of phi and/or pi.

4. The electric generator of claim **1**, wherein the antenna/waveguide is of pyramidal shape.

5. The electric generator of claim **1**, wherein the antenna/waveguide is placed on an insulating base.

6. The electric generator of claim **1**, wherein the antenna/waveguide is at a high voltage during the operation of the generator.

7. The electric generator of claim **1**, wherein the antenna/waveguide voltage is measured by using an E-field antenna.

8. The electric generator of claim **1**, wherein the antenna/waveguide is connected to an oscillator.

9. The electric generator of claim **8**, wherein the oscillator comprises a resonant step-up transformer.

10. The electric generator of claim **1**, wherein the height of the pyramid of the electric generator is from about 0.10 m to about 1000 m.

11. The electric generator of claim **1**, wherein the base surface area of the pyramid is from about 0.01 m^2 to about 1,000,000 m^2.

12. The electric generator of claim **1**, wherein the generator is positioned in the general North-South direction.

13. An electric generator for harvesting the energies of atomic oscillators comprising:

(a) an antenna/waveguide that is geometrically optimized having a conducting surface; and

(b) a primary (apex) coil wound with an insulated conductor over a non-conductive coil form, the coil being connected to an AC or AC-DC driver at its bottom lead and, to the conducting surface of the antenna/waveguide by its top lead near the point where the electric field contacts the antenna/waveguide, and the antenna/waveguide serving as a quasi-capacitive series element to provide a specific resonant frequency; and

(c) a secondary coil of smaller diameter than the primary (apex) coil having a greater number of turns than the primary coil, the secondary coil being positioned coaxially within the primary coil and acting as a resonant step-up transformer winding inductively coupled with the apex coil;

wherein the generator absorbs impulses from Earth's electric oscillations; and

wherein the attracted energy manifests as high voltage sinusoidal waveforms in the secondary coil, representing harvested electrical energy of atomic oscillators and measurable on the leads of the secondary coil.

14. The electric generator of claim **13**, in which more than one resonant step-up transformer winding is used.

15. The electric generator of claim **13**, wherein the electric generator stimulates and attracts the electric emissions of atomic oscillators by the use of high voltage.

16. The electric generator of claim **15**, wherein the high voltage is greater than 500 V_{RMS}.

17. The electric generator of claim **13**, wherein the antenna/waveguide is designed based on functions of phi and/or pi.

18. The electric generator of claim **13**, wherein the antenna/waveguide is of pyramidal shape.

19. The electric generator of claim **13**, wherein the antenna/waveguide is placed on an insulating base.

20. The electric generator of claim **13**, wherein the antenna/waveguide is at a high voltage during the operation of the generator.

21. The electric generator of claim **13**, wherein the antenna/waveguide voltage is measured by using an E-field antenna.

22. The electric generator of claim **13**, wherein the antenna/waveguide is connected to an oscillator.

23. The electric generator of claim **22**, wherein the oscillator comprises a resonant step-up transformer.

24. The electric generator of claim **13**, wherein the primary (apex) coil of the resonant transformer is connected near the point where the electric field contacts the antenna/waveguide.

25. The electric generator of claim **13**, wherein the bottom lead of the secondary coil is connected to ground.

26. The electric generator of claim **13**, wherein the primary (apex) coil is inductively coupled to the secondary coil.

27. The electric generator of claim **13**, wherein the output of the secondary coil is connected to a load.

28. The electric generator of claim **13**, wherein the height of the pyramid of the electric generator is from about 0.10 m to about 1000 m.

29. The electric generator of claim **13**, wherein the base surface area of the pyramid is from about 0.01 m^2 to about 1,000,000 m^2.

30. The electric generator of claim **13**, wherein the generator is positioned in the general North-South direction.

31. An electric generator for harvesting the electric emissions of atomic oscillations comprising an oscillator.

32. The electric generator of claim **31**, wherein the oscillator operates in the LF or ELF bands.

33. The electric generator of claim **31** wherein the electric generator comprises:

(a) a primary (apex) coil wound with a conductor over a secondary coil, the primary (apex) coil being connected electrically at its bottom lead to a driver operating in the LF or ELF bands while connected by its top lead near the point at which the electric field contacts the conductive surface of the antenna/waveguide; and

(b) a secondary coil of smaller diameter than the primary coil having a greater number of turns than the primary coil, the secondary coil being positioned coaxially within the first coil and acting as a resonant step-up transformer winding inductively coupled with the primary;

wherein said resonant step-up transformer's output voltage exceeds 500 V_{RMS};

wherein the electric generator attracts impulses from Earth's electric oscillations;

and wherein the attracted energy manifests as high voltage sinusoidal waveforms representing harvested electric energy of atomic oscillations in the secondary coil.

34. The electric generator of claim **33**, wherein the output of the secondary coil is connected to a load for drawing power from the generator.

35. A method of tapping Earth's electric oscillatory energies comprising the steps of:

(a) positioning the electric generator of claim **1** such that it is exposed to Earth's electric oscillations; and

(b) generating a sinusoidal voltage signal representing harvested electric energy of atomic oscillators by the operation of the generator.

36. A method of tapping Earth's electric oscillatory energies comprising the steps of:

(a) positioning the electric generator of claim **2** such that it is exposed to Earth's electric oscillations; and

(b) generating a sinusoidal voltage signal representing harvested electric energy of atomic oscillators by the operation of the generator.

37. A method of tapping Earth's electric oscillatory energies comprising the steps of:

(a) positioning the electric generator of claim **32** such that it is exposed to Earth's electric oscillations; and

(b) generating a sinusoidal voltage signal representing harvested electric energy of atomic oscillators by the operation of the generator.

(57) **ABSTRACT**

A pyramid electric generator for harvesting the vibrational energies of Earth's atomic oscillators according to the present invention comprises: (1) an antenna/waveguide that is geometrically optimized; (2) a secondary coil wound with an insulated conductor on a nonconductive coil form, the coil being attached electrically to the conducting surface of the antenna/waveguide such that the secondary coil is attached near the point at which the electric field contacts the antenna/waveguide; (3) the antenna/waveguide connected with the secondary coil serving as a quasi-capacitive series element to provide a specific resonant frequency; and (4) a primary coil of a few turns wound around the secondary coil, the secondary coil being positioned coaxially within the primary coil and acting as a resonant step-up transformer winding, inductively coupled with the primary coil. The generator resonantly couples into specific frequencies of Earth's atomic oscillators and extracts electric energy therefrom.

CROSS-REFERENCES

This application is a continuation-in-part of PCT Application Ser. No. PCT/US07/69804 by Grandics, entitled "An Electric Power Converter for Extraction of Atmospheric Electrical Energy," designating the United States and filed on May 25, 2007, which in turn claimed priority from U.S. Provisional Application Ser. No. 60/818,360 by Grandics, also entitled "An Electric Power Converter for Extraction of Atmospheric Electrical Energy," and filed on Jul. 3, 2006. The specifications of these two applications are incorporated herein in their entirety by this reference.

BACKGROUND OF THE INVENTION

This invention relates to the generation of electrical power by drawing energy from Earth's electric field. Earth represents a resonant system in which both atmospheric and telluric electrical processes can be harvested. In U.S. Pat. No. 6,974,110, we have provided an apparatus and method for converting the electrostatic potential energy of Earth's atmosphere. The present invention aims to provide an electric generator that, in addition to tapping atmospheric electric processes, extracts electrical power from the vibrational energy of atomic oscillators by a novel resonant coupling method.

SUMMARY OF THE INVENTION

An electrical generator according to the present invention provides a new method of tapping Earth's electric energy field.

One aspect of the present invention is an apparatus for capturing both atmospheric and telluric electric energies, comprising:

(1) an antenna/waveguide that is geometrically optimized, having a conducting surface;

(2) a primary coil wound with a conductor over a secondary coil, the coil being attached electrically to a driver operating in the LF radio band; and

(3) a secondary coil smaller in diameter than the primary coil having a greater length and a greater number of turns than the primary coil and having a first lead and a second lead, the secondary coil being positioned coaxially within the first coil and acting as a resonant step-up transformer winding, inductively coupled with the primary coil and an external capacitor connected in parallel with the secondary coil to provide a specific resonant frequency; or

(4) a secondary coil smaller in diameter than the primary coil, having a greater length and a greater number of turns than the primary coil and having a first lead and a second lead, the secondary coil being positioned coaxially within the first coil and acting as a resonant step-up transformer winding, inductively coupled with the primary coil and connected with the antenna/waveguide serving as a quasi-capacitive series element to provide a specific resonant frequency;

wherein the conducting surface of the antenna/waveguide is configured such that the secondary coil is connected near the point at which the electric field contacts the antenna/waveguide;

wherein the generator absorbs electromagnetic impulses from Earth's electric field; and wherein a high voltage sinusoidal waveform is generated in the secondary coil representing harvested atmospheric and telluric electrical energy and measurable on the leads of the secondary coil.

Preferably, the antenna/waveguide is of pyramidal shape. When the antenna/waveguide is of pyramidal shape, the secondary coil is preferably connected near or at the apex of the antenna/waveguide.

Another aspect of the present invention is an electric generator for harvesting the electric emissions of atomic oscillations comprising an oscillator. Typically, the oscillator operates in the LF or ELF bands.

Typically, in this aspect of the present invention, the generator comprises:

(1) a primary coil wound with a conductor over a secondary coil, the coil being connected electrically to a driver operating in the LF or ELF bands; and

(2) a secondary coil of smaller diameter than the primary coil having a greater length and a greater number of turns than the primary coil, the secondary coil being positioned coaxially within the first coil and acting as a resonant step-up transformer winding inductively coupled with the primary;

wherein said resonant step-up transformer's output voltage exceeds 500 V_{RMS};

wherein the electric generator attracts impulses from Earth's electric oscillations; and

wherein the attracted energy manifests as high voltage sinusoidal waveforms representing harvested electric energy of atomic oscillations in the secondary coil and measurable on leads of the secondary coil.

Another aspect of the present invention is a method of tapping Earth's electric energy field, comprising these steps:

(1) positioning an electric generator according to the present invention as described above, so that it is exposed to a source of atmospheric and telluric electric energy; and

(2) producing a high-voltage sinusoidal signal representing electrical energy harvested by the operation of the generator.

BRIEF DESCRIPTION OF THE DRAWINGS

The following invention will be better understood with reference to the specification, appended claims, and accompanying drawings, where:

FIG. **1** is a graph showing the formation of electric vortices across and around the pyramid.

FIG. **2** is a graph showing the circuit diagram of the pyramid generator.

FIG. **3** is a graph showing the power in the secondary coil vs. the power in the primary coil.

FIG. **4** is a graph showing the power in the secondary coil vs. the apex voltage on the pyramid.

FIG. **5** is a graph showing the circuit diagram of the pyramid generator with the measurement points.

DETAILED DESCRIPTION OF THE INVENTION

One aspect of the present invention is an electric generator for attracting the electric emissions of atomic oscillations by the use of high voltage, to harvest electric energy therefrom.

One embodiment of this aspect of the invention is an apparatus for capturing atmospheric and telluric electric energies by harvesting the energies of atomic oscillators, comprising:

(1) an antenna/waveguide that is geometrically optimized, having a conducting surface;

(2) a primary coil wound with an insulated conductor, the coil being connected to an AC or AC-DC driver; and

(3) a secondary coil smaller in diameter than the primary coil, having a greater length and a greater number of turns than the primary coil and having a first lead and a second lead, the secondary coil being positioned coaxially within the first coil and acting as a resonant step-up transformer winding,

inductively coupled with the first coil; and an external capacitor connected in parallel with the secondary coil to provide a specific resonant frequency; or

(4) a secondary coil smaller in diameter than the primary coil, having a greater length and a greater number of turns than the primary coil and having a first lead and a second lead, the secondary coil being positioned coaxially within the first coil and acting as a resonant step-up transformer winding, inductively coupled with the first coil and connected with the antenna/waveguide serving as a quasi-capacitive series element to provide a specific resonant frequency, with the secondary coil attached near the point at which the electric field contacts the antenna/waveguide;

wherein the generator absorbs electromagnetic impulses from Earth's electric field; and

wherein a high-voltage, sinusoidal waveform is generated in the secondary coil representing harvested atmospheric and telluric electrical energy and measurable on leads of the secondary coil.

Preferably, the antenna/waveguide is of pyramidal shape. However, any geometric shape can be used for the antenna/waveguide. When it is of pyramidal shape, the secondary coil is preferably connected near or at the apex of the antenna/waveguide. The shape and size of the antenna/waveguide can be optimized depending on the intended use of the generator. Preferably, the antenna/waveguide exhibits ratios of pi and the Fibonacci number (phi).

Typically, the generator further comprises an insulated base on which the antenna/waveguide is placed. The size and shape of the insulated base can also be optimized, depending on the intended use of the generator. The second lead of the secondary coil is typically connected to earth ground.

Typically, the output of the secondary coil is harvested. This can be done by connecting to a rectifier-capacitor-load resistance, or by a third coil inductively coupled with the secondary coil. In one alternative, the output of the secondary coil is coupled to a load for drawing power from the generator. The optimal circuit can be selected by one of ordinary skill in the art to optimize power extraction. The load draws power from the generator. The load can be a resistor, a rectifier or a storage capacitor powering a DC load. Typically, the antenna/waveguide is at a high voltage during the operation of the generator. Typically, the antenna/waveguide voltage is greater than 500 V_{RMS}. The antenna/waveguide can be connected to an oscillator. The oscillator can comprise a resonant step-up transformer.

Typically, the antenna/waveguide is in resonance with the secondary coil. Typically, the primary coil is inductively coupled to the secondary coil.

Typically, the antenna/waveguide is positioned in a generally north-south direction to tap atmospheric and telluric electric energy. In this arrangement, when the antenna/waveguide is of pyramidal shape, the height of the pyramid can be from about 0.5 m to about 1000 m, more typically, from about 0.50 m to about 150 m. The optimal pyramid size is a function of the power requirements. However, a pyramid can be built even 1 km in height. Typically, the base surface area of the pyramid ranges from about 0.25 m^2 to about 1,000,000 m^2; more typically, from about 0.25 m^2 to about 25,000 m^2. Naturally, other heights and base surface areas can be used for particular applications. The numbers of sides can also vary. When the pyramid is small (e.g., 6-feet base length described in this application), there is an insufficient atmospheric potential on its apex to trigger the attraction of power. In such event, an AC or AC-DC driver is necessary to bring the pyramid to the electric potential necessary. A suitable voltage is typically greater than 500 V_{RMS}.

In one alternative, the primary coil is wound with a conductor over the secondary coil, the primary coil being connected electrically to a driver operating in the LF or ELF bands.

Another aspect of the present invention is an electric generator for harvesting the electric emissions of atomic oscillations comprising an oscillator. Typically, the oscillator operates in the LF or ELF bands.

Typically, in this aspect of the present invention, the generator comprises:

(1) a primary coil wound with a conductor over a secondary coil, the coil being connected electrically to a driver operating in the LF or ELF bands; and

(2) a secondary coil of smaller diameter than the primary coil having a greater length and a greater number of turns than the primary coil, the secondary coil being positioned coaxially within the first coil and acting as a resonant step-up transformer winding inductively coupled with the primary;

wherein said resonant step-up transformer's output voltage exceeds 500 V_{RMS};

wherein the electric generator attracts impulses from Earth's electric oscillations; and

wherein the attracted energy manifests as high voltage sinusoidal waveforms representing harvested electric energy of atomic oscillations in the secondary coil and measurable on leads of the secondary coil.

In this alternative, the output of the secondary coil can be coupled to a load for drawing power from the generator.

Another aspect of the invention is a method of tapping Earth's electric energy based on the following concepts:

(1) utilizing a pyramidal antenna/waveguide designed based on the ratios of pi and phi;

(2) using the antenna/waveguide to absorb and focus specific frequencies of Earth's electric field;

(3) positioning a resonant coil system connected to said antenna/waveguide near or at its apex according to the present invention; and

(4) generating a high-voltage sinusoidal signal, representing harvested atmospheric and telluric electrical energy, by the operation of the coil system.

Typically, in this method, the method comprises the steps of:

(1) positioning an electric generator according to the present invention as described above such that it is exposed to Earth's electric oscillations; and

(2) generating a high voltage sinusoidal signal representing harvested electric energy of atomic oscillators by the operation of the generator.

Typically, the harvested electric energy can be fed into a power grid for distribution, but smaller units capable of distributed power generation or for use as stand-alone generators are also feasible by the concept of this invention.

The invention is described by the following Example. This Example is included for illustrative purposes only and is not intended to limit the invention.

EXAMPLE

We have introduced a new theory of space, energy and matter that predicted that electromagnetic interaction propagates through a carrier medium called the space lattice that is made up of pulsating, phi-based spiral vortices (STAR), the excitation of which generates propagating sinusoidal lines of force across the space lattice recorded as electromagnetic waves by our instruments [1,2]. We have also predicted that natural pressure gradients exist within the space lattice that can be used for power generation by inserting a capacitor into such gradient. Furthermore, we proposed that a pyramid-shaped capacitor is an optimally shaped device for tapping the energy gradient of the space lattice that manifests in the form of an electrical potential gradient in Earth's atmosphere. This was demonstrated subsequently [3-5]. We also found that the pyramid-shaped capacitor design should be based on ratios of pi and phi [5] because electrical energy propagates along a phi-based spiral [6].

We suggested that elemental particles are composed of STAR oscillators that make up the space lattice by electromagnetic compression of its elemental cubes into pulsating conical/vortexual subunits that form the basis for all particles of matter [1,2]. We proposed that atomic and subatomic oscillators could vibrate in a very wide frequency range from sub-acoustic to extremely high EM frequencies [1,2]. This does not mean that material bodies can take or maintain a physical form at any energy level, but this allows the recycling of atoms into the space lattice as part of their natural evolution [2,6].

Atomic oscillators are constantly in motion, and such motion is electric because all motion and energy is fundamentally electric [2,6]. It is known that atomic bodies constantly exchange electric energy. Such energy flow can be harvested when the spiral physical nature of electric waves is recognized. Russell observed that energy always moves during its generative cycle in spirals towards the higher potential [7]; therefore, we reasoned that an "attractor" of high electric potential must be provided to pull in the random electromagnetic emissions of atomic oscillators. The "attractor" must function as a phi-based antenna/waveguide to focus the phi-based electric emissions of atomic bodies into the apex of a vortex, the same method Nature uses for power multiplication [6,7]. Therefore, a phi-based pyramidal antenna/waveguide must be at a high voltage in order to perform its attractor function.

As all material manifestations are tonal [8], acoustic vibrations are always generated during the oscillations of atomic bodies, even though they are inaudible most of the time. Sometimes, however, they are detected; one such example is Earth's hum [9-11]. Earth's solid mass and its atmosphere represent a coupled resonant system, and is therefore our expanded target power source. Acoustic waves are also electrical [8] and can be harvested. To achieve this goal, the geometrically optimized pyramidal antenna/waveguide must be connected to an oscillator that operates at a high voltage and is tuned to a suitably selected frequency.

The appropriate resonant frequency is dictated by practical considerations. Atomic oscillators can vibrate in a very wide frequency range [1,2,6-8] but short wavelength radiations are readily re-absorbed by atoms and are rapidly attenuated; therefore, long wavelength electromagnetic emissions must be targeted. The operation of the pyramid generator is feasible in the ELF to the LF range. As electric radiation propagates in a vortex [2,6-8], the emitted electric vortex over the pyramidal antenna (FIG. **1**) increases its "size," and so it is capable of funneling atmospheric electromagnetic emissions of the same frequency back into the antenna/receiver. Thus, the pyramid electric generator could capture the energy emitted by both telluric and atmospheric atomic oscillators. We have tested these assumptions and demonstrated the basic principles of an electric generator.

Methods and Results

In our previous papers, we reported that a pyramid-shaped capacitor/antenna converts atmospheric electrostatic discharge impulses (ESD) into a periodic high-frequency signal that can be detected in an insulated coil placed in proximity of the capacitor [3,4]. Here, we report on further developments including a new design for the resonant coil system and an expanded range of energy sources targeted. A Tektronix TPS 2024 digital oscilloscope was used for signal acquisition and analysis, and Tektronix A503 current amplifiers were used with the Tektronix A6302 and A6303 probes for current measurement. High voltage was measured using a Tektronix P6015 probe. An ENI-1140LA amplifier was used to activate the primary coil of the resonant coil system at the selected frequency.

For the experiments, we used a geometrically optimized pyramid-shaped antenna/waveguide [3-5]. The pyramid expressed ratios of pi and phi and was approximately a 1:125 scaled down replica of the Great Pyramid of Giza (GPF), 6 feet base length. The pyramid was built of a wooden frame and covered with triangular copper sheets of 0.66 mm thickness on its sides that were electrically connected. It was placed on an insulating base and positioned in the general North-South direction.

The secondary coil (coil **2**) was wound with a 20 AWG insulated magnet wire with a monofilament nylon spacer (0.06 mm diameter) between the turns on a fiberglass cylindrical coil form, and connected to the conducting surface of the pyramid near its apex. Thus, the secondary coil was connected with the pyramidal antenna/waveguide as a quasi-capacitive series element to provide a specific resonant frequency with coupling to the surrounding electromagnetic environment. The other lead of coil **2** was grounded (FIG. **2**). The purpose of the monofilament spacer was to reduce inter-winding capacitance in coil **2** by increasing distance between wire turns of the coil.

A primary coil of larger diameter (coil **1**) was wound on or near the lower cylindrical volume of coil **2** with the lead connected to earth ground, and served as a driver coil inductively coupled with the secondary (coil **2**). The secondary was isolated from the primary by layers of silicon rubber and foam. The two coils make a resonant step-up transformer, the parameters of which are shown in Table 1.

TABLE 1

Physical and Electrical Parameters of the Resonant Transformer	
Secondary turns of wire	840 turns
Height	0.85 m
Wire diameter	0.00081 m
Primary turns of wire	5 + 9/10 turns
Height	0.21 m
Wire diameter	¼" O.D. copper pipe with .030" wall thickness
Primary	
Inductance	98 μH
Resistance	0.118 ohms
Secondary	
Inductance	24.16 mH
Resistance	24.42 ohms
Capacitance	1040 nF
Winding ratio	1:143
Mutual inductance	6.13 mH

In the experiment; the controlled variable was the voltage, which was increased in steps until the maximum voltage in the secondary (permitted by circuit components and test equipment) was achieved for the given resonant frequency. The objective was to "drive the atmosphere" by radiating a high voltage (~20 kV p-p), LF (40-120 kHz) signal developed by the high ratio step-up transformer and fed by a powerful signal generator at a resonant frequency either with an L-C resonant secondary coil, or a resonance determined by the pyramid as a quasi-capacitive series element connected to the secondary coil of the transformer and radiating to the local atmosphere. The data are shown in Table 2.

The experimental data are shown in Table 2. The current readings were also confirmed by using "current sensing" resistors (not shown). A apparent power gain of nearly 100-fold was achieved in the secondary coil relative to input power in the primary coil, and a linear increase of power in the secondary coil with the increase of input power into the primary coil (FIG. **3**). The power in the secondary coil exponentially increases with the pyramid apex voltage (FIG. **4**).

TABLE 2

Power Measurements in the Pyramid-Resonant Coil System

Primary								
Frequency (kHz)	83.00							
$V_{P\ RMS}$	3.97	6.38	9.86	20.3	26.7	33.8	39	40.8

$I_{A\ RMS}$ (mA)	62.2	148	193	438	579	728	834	919
$I_{A\ angle\ with\ respect\ to}V_S$	42°	43°	44°	52°	52°	54°	53°	52°
Total power (VA)	21.2	129.5	222.8	1552	2707.8	4530.2	5957.5	7087.3
True power (W)	15.7	94.7	160.3	956	1668.1	2664.5	3587.6	4366
Power sec/prim	61.1	91.4	75.4	96.9	91.2	96.9	99.4	94.8

A load may be connected to coil **2** to draw power from the system. The load may also be connected via a tertiary coil inductively coupled to the secondary coil. The load may be a resistor, a rectifier or storage capacitor powering a DC load.

A graphic representation of the test system is shown in FIG. **5**. The pyramidal antenna/waveguide, placed on an insulating base, is coupled to the surrounding electromagnetic environment and serves as an antenna/waveguide for the concentration of atmospheric and telluric electromagnetic oscillations at resonance frequency. As the flow of electric energy is always balanced [6], two vortices may cross the pyramidal antenna: one from the direction of the ground concentrating into its apex, and another one from its apex propagating into the atmosphere (FIG. **1**). The atmospheric electric vortex possibly acts as an ionic antenna pulling in EM radiations from a large atmospheric domain. In FIG. **5**, the antenna/waveguide **10** is attached to a coil **12**. To drive the system, a RF generator **14** is connected to a signal amplifier **16**. The signal amplifier **16** is also connected to an uninterruptible power supply (UPS) **18** through a sinewave generator **20** and a frequency counter **22**. Outputs from the sinewave generator **20** and frequency counter **22** are also connected to a first current amplifier **24**. The output from the antenna/waveguide **10** and coil **12** are also connected to a second current amplifier **26**. The sinewave generator **20**, frequency counter **22**, first current amplifier **24**, and second current amplifier **26** are connected to a digital oscilloscope **28**. Outputs from the antenna/waveguide **10** and coil **12** are also connected to the digital oscilloscope **28**. A laptop computer **30** controls the sinewave generator **20** and frequency counter **22**.

The pyramid's apex is attached to a coil of high turn number (FIGS. **2** & **4**). This secondary coil wound on a nonconductive coil form serves as a step-up transformer, and forms a resonant circuit with the pyramid that acts as a quasi-capacitive series element. The secondary coil is activated by a signal from an RF generator via a primary coil of a few turn numbers inductively coupled to coil **2**. The measurement points are also indicated, displaying the positions of voltage and current probes. The data are captured by a digital oscilloscope and recorded on a laptop computer.

Discussion

This invention demonstrates a novel approach to harvest Earth's electric energy. The masses of Earth and its atmosphere represent a coupled resonant system that is continually electrified by solar radiation. We have found that a pyramidal antenna designed based on the ratios of phi and pi is optimal for the capture of atmospheric electrostatic discharge (ESD) impulses [3-5]. Atmospheric ESD is a product of solar radiation and is a wide bandwidth phenomenon. The pyramid as a wideband, non-resonant antenna is uniquely adapted to harvest the energy of atmospheric ESD.

This invention also points out an additional energizing mechanism at work during the operation of the pyramid electric generator. The observation is derived from our theory on energy, matter and space [1,2] as well as that of Russell [6,7]. Both Russell and we observed that spiral motion is a fundamental action of matter and that the vortex is the mechanism of power multiplication in Nature. A vortex concentrates power into its apex where the highest velocity of motion, the highest pressure and the highest electric potential resides [1,2,6,7]. As electricity propagates along a pulsating phi-based spiral [6,7], a phi-based antenna/waveguide is suitable to focus its energy into the apex of a vortex inside the antenna. A phi-based pyramid is optimal for this purpose.

As atomic bodies can oscillate in a very wide frequency range [1,2,6-8], a pyramidal antenna/waveguide coupled to an oscillator that is tuned to a suitable frequency can focus the "electric noise" from Earth's atomic oscillators into the apex of the pyramid at a high voltage. Russell observed that energy moves towards the higher potential during its generative cycle [7]; therefore, it is essential that the pyramidal antenna be at a high potential. Our data corroborated this assumption.

To select a suitable frequency range, one can begin with the observation that all material manifestations are tonal [8], and that acoustic frequencies are always generated during the oscillations of atomic bodies even though they remain inaudible most of the time. Acoustic waves are also electric [8] and therefore Earth's enormous mass and its atmosphere represent a coupled resonant system that offer a vast source of power.

For practical reasons on our small pyramid, we have chosen a frequency above the audio range but below the radio frequency spectrum; our antenna was made to radiate at the target wavelength. The wavelength of the 50-120 kHz range is 6 km to 25 km, thus allowing energy to be harvested over a large atmospheric domain. As electrical energy propagates in a vortex [6,7], the emitted electric vortex (ionic antenna) over the pyramidal antenna/waveguide increases its "size" and enables it to funnel the same frequency atmospheric electromagnetic radiations back into the antenna. Thus, the pyramid electric generator captures at the selected frequency the energy emitted by Earth's atomic oscillators.

The presence of an electric (ionic) vortex was demonstrated by radar testing of the space over a 44 m tall fiberglass pyramid located near Moscow [12]. The Russians found that the large ionized column of air over the area of the vertical axis of the pyramid had a width of about 500 m and reached an altitude of 2 km. It is remarkable that this effect was induced by a nonconductive pyramid surface demonstrating a significant degree of atmospheric ionization even under fair weather conditions. Thus, a suitably sized large or an electrically activated small pyramid should open a low impedance path to higher elevations of relatively conductive atmospheric domains.

In conclusion, the total power that can be extracted from Earth's atomic oscillators must be extremely large, likely far exceeding current global electric generation capacity. In our experiment, we obtained over 7000 VA power at about 20 kV p-p pyramid voltage using a 6 feet base length pyramid. This power is nearly 100 times greater than the power necessary to drive the pyramid to the required operating voltage. By constructing the pyramid generator from dedicated high voltage components and using higher drive voltages, a significant increase in power output is envisioned. The power extraction will also be enhanced by further optimization of the designs of both the pyramid and the coil system.

The power output will also increase by employing larger pyramid structures and coils. As voltage is the primary factor in attracting power into the system, the necessary voltage can be provided by the vertical atmospheric potential on a tall pyramid. Since the atmospheric vertical potential gradient could go as high as 1200 V/m near Earth's surface under fair weather conditions [13], a pyramid height of 80-150 m seems sufficient to provide the apex voltage for a self-sustaining power generator. As the pyramid scales up volumetrically, a power generator pyramid of the size range of the GPG could likely have an output in the hundreds to thousands of megawatts range. Groups of several pyramid electric generators could be placed within specific geographical areas, thus combining their energy harvesting capacity.

ADVANTAGES OF THE INVENTION

The present invention provides a new method of tapping Earth's electric energy and providing usable power that can be fed into a power grid or supplied by stand-alone power generators. It does so without the need for mechanical energy or the consumption of fossil fuel or the long-term risks associated with power generated by nuclear fission, including the risk of diversion of fissionable material to terrorist aims or the risk posed by the required long-term storage of spent nuclear fuel. Devices according to the present invention can operate virtually continuously with little to no maintenance.

With respect to ranges of values, the invention encompasses each intervening value between the upper and lower limits of the range to at least a tenth of the lower limit's unit, unless the context clearly indicates otherwise. Moreover, the invention encompasses any other stated intervening values and ranges including either or both of the upper and lower limits of the range, unless specifically excluded from the stated range.

Unless defined otherwise, the meanings of all technical and scientific terms used herein are those commonly understood by one of ordinary skill in the art to which this invention belongs. One of ordinary skill in the art will also appreciate that any methods and materials similar or equivalent to those described herein can also be used to practice or test this invention.

The publications and patents discussed herein are provided solely for their disclosure prior to the filing date of the present application. Nothing herein is to be construed as an admission that the present invention is not entitled to antedate such publication by virtue of prior invention. Further the dates of publication provided may be different from the actual publication dates which may need to be independently confirmed.

All the publications cited are incorporated herein by reference in their entireties, including all published patents, patent applications, and literature references, as well as those publications that have been incorporated in those published documents. However, to the extent that any publication incorporated herein by reference refers to information to be published, applicants do not admit that any such information published after the filing date of this application is to be considered prior art.

As used in this specification and in the appended claims, the singular forms include the plural forms. For example the terms "a," "an," and "the" include plural references unless the content clearly dictates otherwise. Additionally, the term "at least" preceding a series of elements is to be understood as referring to every element in the series. The inventions illustratively described herein can suitably be practiced in the absence of any element or elements, limitation or limitations, not specifically disclosed herein. Thus, for example, the terms "comprising," "including," "containing," etc. shall be read expansively and without limitation. Additionally, the terms and expressions employed herein have been used as terms of description and not of limitation, and there is no intention in the use of such terms and expressions of excluding any equivalents of the future shown and described or any portion thereof, and it is recognized that various modifications are possible within the scope of the invention claimed. Thus, it should be understood that although the present invention has been specifically disclosed by preferred embodiments and optional features, modification and variation of the inventions herein disclosed can be resorted to by those skilled in the art, and that such modifications and variations are considered to be within the scope of the inventions disclosed herein. The inventions have been described broadly and generically herein. Each of the narrower species and subgeneric groupings falling within the scope of the generic disclosure also form part of these inventions. This includes the generic description of each invention with a proviso or negative limitation removing any subject matter from the genus, regardless of whether or not the excised materials specifically resided therein. In addition, where features or aspects of an invention are described in terms of the Markush group, those schooled in the art will recognize that the invention is also thereby described in terms of any individual member or subgroup of members of the Markush group. It is also to be understood that the above description is intended to be illustrative and not restrictive. Many embodiments will be apparent to those of in the art upon reviewing the above description. The scope of the invention should therefore, be determined not with reference to the above description, but should instead be determined with reference to the appended claims, along with the full scope of equivalents to which such claims are entitled. Those skilled in the art will recognize, or will be able to ascertain using no more than routine experimentation, many equivalents to the specific embodiments of the invention described. Such equivalents are intended to be encompassed by the following claims.

I claim:

1. An electric generator for harvesting the energies of atomic oscillators comprising:

(a) an antenna/waveguide that is geometrically optimized having a conducting surface;

(b) a primary coil wound with an insulated conductor over a secondary coil, the coil being connected to an AC or AC-DC driver; and

(c) a secondary coil of smaller diameter than the primary coil having a greater length and a greater number of turns than the primary coil and having a first lead and a second lead, the secondary coil being positioned coaxially within the first coil and acting as a resonant step-up transformer winding inductively coupled with the primary and an external capacitor connected in parallel with the secondary coil to provide a specific resonant frequency; or

(d) a secondary coil of smaller diameter than the primary coil having a greater length and a greater number of turns than the primary coil and having a first lead and a second lead, the secondary coil being positioned coaxially within the first coil and acting as a resonant step-up transformer winding inductively coupled with the primary and connected with the antenna/waveguide serving as a quasi-capacitive series element to provide a specific resonant frequency;

wherein the conducting surface of the antenna/waveguide is configured such that the secondary coil is attached near the point at which the electric field contacts the antenna/waveguide;

wherein the generator absorbs impulses from Earth's electric oscillations; and wherein the attracted energy manifests as high voltage sinusoidal waveforms in the secondary coil, representing harvested atmospheric and telluric electrical energy and measurable on the leads of the secondary coil.

2. The electric generator of claim 1, wherein a suitable voltage is greater than 500 V_{RMS}.

3. The electric generator of claim 1, wherein the antenna/waveguide is designed based on ratios of pi and phi.

4. The electric generator of claim 1, wherein the antenna/waveguide is of pyramidal shape.

5. The electric generator of claim 1, wherein the antenna/waveguide is placed on an insulated base.

6. The electric generator of claim 1, wherein the antenna/waveguide is at a high voltage during the operation of the generator.

7. The electric generator of claim 6, wherein the antenna/waveguide voltage is greater than 500 V_{RMS}.

8. The electric generator of claim 1, wherein the antenna/waveguide is connected to an oscillator.

9. The electric generator of claim 8, wherein the oscillator comprises a resonant step-up transformer.

10. The electric generator of claim 4, wherein the secondary coil of the transformer is connected near the apex of the antenna/waveguide.

11. The electric generator of claim 1 wherein the second lead of the secondary coil is connected to earth ground.

12. The electric generator of claim 1 wherein the primary coil is wound with a conductor over the secondary coil, the primary coil being connected electrically to a driver operating in the LF or ELF bands.

13. The electric generator of claim 1, wherein the primary coil is inductively coupled to the secondary coil.

14. An electric generator for harvesting the electric emissions of atomic oscillations of claim 1 comprising an oscillator.

15. The electric generator of claim 14, wherein said oscillator operates in the LF or ELF bands.

16. The electric generator of claim 14 wherein the generator comprises:

(a) a primary coil wound with a conductor over a secondary coil, the coil being connected electrically to a driver operating in the LF or ELF bands; and

(b) a secondary coil of smaller diameter than the primary coil having a greater length and a greater number of turns than the primary coil, the secondary coil being positioned coaxially within the first coil and acting as a resonant step-up transformer winding inductively coupled with the primary; wherein said resonant step-up transformer's output voltage exceeds 500V_{RMS};

wherein the electric generator attracts impulses from Earth's electric oscillations; and wherein the attracted energy manifests as high voltage sinusoidal waveforms representing harvested electric energy of atomic oscillations in the secondary coil and measurable on leads of the secondary coil.

17. The electric generator of claim **4**, wherein the height of the pyramidal electric generator is from about 0.50 m to about 1000 m.

18. The electric generator of claim **4**, wherein the base surface area of the pyramid is from about 0.25 m^2 to about 1,000,000 m^2.

19. The electric generator of claim **1**, wherein the generator is positioned in a generally north-south direction.

(57) ABSTRACT

A new method is described to produce useful electrical energy from DC electrostatic fields using a pyramid-shaped capacitor. The system uses no moving parts and no mechanical energy is introduced. Also, when a pyramid-shaped electrode is charged with DC high voltage, a propulsive force is generated. This will allow the manufacture of vehicles capable of levitation and flight.

METHOD AND APPARATUS FOR CONVERTING ELECTROSTATIC POTENTIAL ENERGY

CROSS-REFERENCES

This application is a continuation-in-part of application Ser. No. 09/732,110, filed Dec. 7, 2000, now abandoned, entitled "Method and Apparatus for Converting Electrostatic Potential Energy," by Peter Grandics, which claims the benefit of Provisional application Ser. No. 60/169,378, filed Dec. 7, 1999, which is incorporated herein in its entirety by this reference.

BACKGROUND OF THE INVENTION

This invention relates to the generation of electrical power by drawing energy from an electrostatic potential field. The conversion of DC electrostatic energy into useable electrical energy by electrostatic generators is already described in the prior art as disclosed in U.S. Pat. Nos. 3,013,201, 4,127,804, 4,151,409 and 4,595,852. Generally, such prior art electrostatic generators utilize mechanical energy to separate charges and thus contain complex mechanics that is difficult to scale up for a high output system. Therefore, the present invention aims to provide an electrostatic generator in which electrical power is derived exclusively from the energy of DC electrostatic fields without the input of mechanical power.

SUMMARY OF THE INVENTION

Pursuant to this invention a simple technique is described to convert the energy of a DC electrostatic field into an alternating current by wrapping a coil around the pyramid. The resulting AC current can be rectified and used for practical purposes. A pyramid-shaped capacitor can also be used in an inverse mode of operation for the generation of propulsive force.

Accordingly, one embodiment of the present invention is a method for converting DC electrostatic energy into usable electrical energy, the method comprising the steps of:

(1) providing a capacitor of pyramidal shape;

(2) placing an insulated coil on the surface of the capacitor, the coil having leads;

(3) attaching a rectifier to the leads of the coil, the rectifier having leads; and

(4) attaching a capacitor or a battery to the leads of the rectifier so that DC electrostatic energy is converted into usable electrical energy.

Another embodiment of the present invention comprises a method for converting DC electrostatic energy into propulsive force comprising the steps of:

(1) providing a first capacitor of pyramidal shape;

(2) placing an insulated conductive tip on the point of the capacitor;

(3) providing a static generator for charging the capacitor, and

(4) attaching 3 ball-shaped smaller capacitors to the bottom of the pyramidal-shaped capacitor; and

(5) providing means to extend or retract the ball-shaped capacitors from the pyramidal-shaped capacitor, so DC electrostatic energy is converted into propulsive force by the action of the first capacitor and the 3 ball-shaped smaller capacitors provide directional control.

BRIEF DESCRIPTION OF THE DRAWINGS

The following invention will become better understood with reference to the specification, appended claims, and accompanying drawings, where:

FIG. **1** is a diagram demonstrating the pyramid experimental setup;

FIG. **2** is the pyramid coil signal as detected by oscilloscope; and

FIG. **3** is a diagram demonstrating power transmission on the pyramid setup.

DESCRIPTION OF THE PREFERRED EMBODIMENT

Pursuant to this invention, a novel method is described to convert DC electrostatic energy into an AC current that can be rectified and used for practical purposes. The shape of the capacitor and the body of such device is designed to convert the DC electrostatic energy into the AC current for maximal effect.

A pyramidal or conical shape is preferred for one of the capacitor electrodes (FIG. **1**). In FIG. **1**, a detector coil **102** is provided that is in turn connected to an oscilloscope **104**. The coil surrounds the metallic pyramid **100**. In the experimental setup shown, the field is established between a top plate **106** and the pyramid **100** by using a ground **108** connected to a source of DC electrical energy **110**. When a high voltage DC field (30 kV) is established on such capacitor, a regularly repeating, clocklike signal is detected in the coil placed on the pyramid's surface (FIG. **2**). This is an unexpected observation as corona discharges are irregular by nature.

The alternating current from the coil can be rectified and used for practical purposes. If a suitable DC electrostatic field could be found in nature, this principle would be useful in tapping the energy of such field. To test for this possibility, I have measured the rectified signal from the coil without an external power source. The rectified coil output was collected in a capacitor and voltage measured in 1 h intervals. The voltage measured is significantly higher if the capacitor electrode is pyramid-shaped as opposed to a box-shaped electrode of the same height and volume. When the pyramid is placed into a Faraday cage, the signal is abolished (see details in the Example). The data has demonstrated in principle that with this experimental setup electrical energy can be extracted from the Earth's electrostatic field. The Earth's surface and the ionosphere substitutes for the two charged electrodes, which exhibit negative and positive polarities, respectively.

Atmospheric electricity manifests as a buildup of electrostatic energy, a phenomenon that permanently electrifies our environment (Anderson, R. V. in Electrical Processes in Atmospheres, H. Holezalek and R. Reiter, eds., (Steinkopff, Darmstadt, 1977) pp. 87–99). The voltage gradient between the Earth's surface and the ionosphere is thought to be maintained by the electrical activity of the troposphere as well as the solar wind-coupled magnetospheric dynamo (Roble, R. G. Tzur, I. in The Earth's Electrical Environment, Studies in Geophysics (National Academy Press, Washington D.C., 1986) pp. 206–231). The Earth's electrostatic field is never depleted, despite the constant discharges of energy. There are two segments of atmospheric electrical processes that potentially could be tapped, fair weather and thunderstorm related atmospheric electrical phenomena.

The Earth's voltage field creates a potential difference of about 400,000 V (Feynman, R. P. Lectures on Physics (Addison Wesley, Inc., Palo Alto, Calif., 1964) v.2, Chapter 9), with a voltage gradient of about 200–300 V/m around the surface of the Earth (W. Gringell, J. M. Rosen, D. I. Hofmann, in The Earth's Electrical Environment, Studies in Geophysics (National Academy Press, Washington D.C.,

1986) pp. 166–182). Given this voltage drop of 200–300 V/m, the desired 30 kV potential can be obtained at a pyramid height of about 100–150 m.

Due to the evolving nature of our understanding of atmospheric electrical processes, we do not have a clear picture of the magnitude of electrical energy generated (and dissipated) in the global atmospheric electrical circuit by localized convective phenomena. Direct measurement of the atmospheric vertical potential difference using tethered balloons have shown that under fair weather conditions and at low altitudes (150–550 m), short circuit currents on the order of 10 μA were obtained with a single wire collector yielding a power of about 1 W (Holzworth, R. H. et al., Direct measurement of lower atmospheric vertical potential differences, Geophys. Res. Lett. 8, 783–786 (1981), and Holzworth, R. H. Hy-wire measurement of atmospheric potential, J. Geophys. Res. 89, 1395–1401 (1984)).

These data remarkably demonstrated that it is possible to couple to a large portion of the atmosphere and also gave an indirect proof of the presence of a fair weather convective generation process. Since at a low altitude of 1500 m, the entire atmospheric vertical electric potential (400 kV) could be bridged, it may even be possible to couple right into ionospheric electrical processes (Holzworth, R. H. et al., Direct measurement of lower atmospheric vertical potential differences, Geophys. Res. Lett. 8,783–786 (1981)). This would significantly expand the available energy pool for this device.

The other possibility is to tap localized peaks of atmospheric electrical activity arising from thunderstorm activity. The approximate order of magnitude of electrostatic energy generated in the troposphere could be estimated by the amount of energy dissipated by lightning discharges. The estimates for the total number of lightning strikes over the entire surface of the Earth vary from 100 to 300 per second (Orville, R. E. in The Earth's Electrical Environment, Studies in Geophysics (National Academy Press. Washington D.C., 1986) pp. 23–29). The estimate for the power discharged in an average lightning event is 10^{12} watts over a time period of about 0.2 sec (Christian, H. J. and McCook, M. A. in A lightning primer at http://thunder.msfc.nasa.gov/). This yields a total of $2–6\times10^{13}$ W-sec of electrical energy spent by lightning discharges globally in each second, or approximately 4×10^{17} W-h per year. Over 90% of all lightning occur over landmasses. The distribution of tropospheric electrical activity is highly concentrated, the major production zones being Central Africa, the south central United States and the Amazon Basin (Miller, T. L. Global lighting activity at http://www.ghcc.msfc.nasa.gov/rotating/otd_oval_full.html). This suggests that the density of atmospheric electrical activity in these zones may be high enough to tap.

The current annual global electricity production by the world's power generating industry is $1,22\times10^{16}$ W-h (Seth, A. Nuclear power and its role in global electricity and energy, Institute for Energy and Environmental Research, at http://www.ieer.org/ensec/no-1/glbnrg.html (1997)) which is only a small fraction, about 1⁄30th, of the electricity generated and discharged naturally by lightning activity. As lightning represents only peak charge density events, the localized total charge production of thunderstorms is necessarily underestimated by a factor, the magnitude of which is still unknown.

These indicate that atmospheric electricity, if harnessed, could meet all the energy needs of mankind. This invention describes a new electrical phenomenon that allows the conversion of electrostatic energy into an alternating current.

Research on the average electrical power generated and dissipated by the Earth's global electrical circuit suggests that about 2000 thunderstorms are in progress at any given time, and that the average storm current delivered to the ionosphere is of the order of one ampere (Roble, R. G. Tzur, I. in The Earth's Electrical Environment, Studies in Geophysics (National Academy Press, Washington D.C., 1986) pp. 206–231). The potential difference between the Earth and the ionosphere is of the order of 500 kV; therefore, the total source power is of the order $2000\times1\times5\times10^{5}$, or 10_9 watts over the entire planet. Thunderstorms produce an average of one to several nanoamperes per square meter at the surface (Standler, R. B. and Winn, W. P. Quart. J. Met. Soc. 105 285 (1979)). These estimates would suggest that there might not be sufficient energy to tap.

However, the limitation of these low, average Earth surface current densities is not applicable to the pyramid collector for several reasons. In thunderstorms, terawatts of electrical power are generated over relatively long periods of time. To capture this electric power and prevent its dissipation, an effective "charge sink" is necessary. The sub-optimal geometry of the Earth's surface terrain and its relatively low conductivity produce an ineffective sink which leads to small ground surface current densities. A metal pyramid, however, due to its optimal geometry and construction acts as an effective charge sink.

FIG. **3** shows power transmission on the pyramid setup. In FIG. **3**, a pyramid **200** as described above is in contact with a coil **202** and a bridge rectifier **204**. The latter is charging capacitor **206** which feeds load **208**. Oscilloscope **210** measures the voltage drop on the load.

Accordingly, one embodiment of the invention is a method for converting DC electrostatic energy into usable electrical energy, the method comprising the steps of:

(1) providing a capacitor of pyramidal shape;

(2) placing an insulated coil on the surface of the capacitor, the coil having leads;

(3) attaching a rectifier to the leads of the coil, the rectifier having leads; and

(4) attaching a capacitor or a battery to the leads of the rectifier so that DC electrostatic energy is converted into usable electrical energy.

As detailed below, typically, a clock-like signal is detected from the leads of the coil. The signal can be rectified, pooled in a capacitor, or pooled in a battery.

A production pyramid, with a projected 40,000 m^2 base surface area, a height of 150 m, and a metallic composition would provide a far more effective charge sink than the surrounding ground surface. As current always flows in the direction of least resistance, this would lead to a concentrated flow of current from the thunderclouds into the pyramid. As a result, a column of air above the surface of the pyramid would become highly ionized and much more conductive than the air in the surrounding area. This would ensure a rapid transfer of charges from the thunderclouds into the pyramid. Therefore, the current flowing into the pyramid would likely be very strong. As a result, lightning activity could be reduced or abolished. In addition, since the threshold effect causes exponential power amplification, such a pyramid could produce very large quantities of electrical energy.

The generation of thunderstorm-related electrical energy in the atmosphere shows a high degree of concentration into three major geographical zones (Miller, T. L. Global lightning activity at http://www.ghcc.msfc.nasa.gov/rotating/otd_oval_full.html). By placing energy-producing pyramids into these zones of high-energy electrical activity, vast quantities of electricity could be obtained. Atmospheric electricity would be a renewable, clean energy source, and could give us the opportunity to begin reversing the process of global warming caused by anthropogenic greenhouse gas emissions. This process, which now produces well-measurable results, threatens to upset our ecosystem with unpredictable consequences (Kerr, R. A. Science 286 1828 (1999)).

Electrostatic energy could also be used to produce a propulsive force. A capacitor made into the shape of a pyramid or cone is suitable. The conductive elements of the capacitor are layered into the pyramidal or conical segment of the hull of such craft. Optimally, there should be several layers of negatively charged conductors on the outside while a single layer of positively charged conductor is in the inside of the craft. All conductive elements should be carefully insulated in order to maintain the charges inside the capacitor.

In the center of the craft, a conductive, insulated pole is mounted such that the pole extends out into the exterior at the top of the craft. The tip of that pole has a metal ball mounted on which is also positively charged. When all capacitor plates are charged, a pressure differential is induced and above the craft the pressure will be higher than at the bottom of the craft. This pressure differential is unstable and progresses towards an equilibrium. It will propel the craft forward in order to eliminate the pressure gradient. This requires that a sufficiently high voltage (>100,000 V) be applied. The capacitors incorporated into the hull will give control over the lift.

To obtain directional control over all three axes of movement, three capacitors need to be mounted at the bottom of the craft placed 120° apart from each other. These capacitors could take the shape of a ball and would be mounted on retractable shafts. The top half of the capacitors would be positively charged while the bottom half is negatively charged. When in flight, the capacitors are retracted and charged based on the needs of directional control so that the ball-shaped capacitors provide lateral movement control for the vehicle. To achieve forward movement, the charges on one capacitor facing the direction of the desired path should be reduced relative to the other two capacitors. This would make the craft tilt forward and start moving in that direction. An alternative method of lateral directional control could be obtained by dividing the capacitor bank inside the hull into segments which segments would be charged individually.

Upon landing, the three ball capacitors would be protracted on their shafts and serve as landing gear. On landing, they would be discharged because the earth is the greater ground. On launching, the main capacitors of the hull would be activated leading to takeoff. The three-capacitor landing gear would then be retracted and charged up so that they can function for lateral directional control after takeoff. On-board static generators would supply voltage required for the operation of the craft.

Accordingly, another embodiment of the invention comprises a method for converting DC electrostatic energy into propulsive force comprising the steps of:

(1) providing a first capacitor of pyramidal shape;

(2) placing an insulated conductive tip on the point of the capacitor;

(3) providing a static generator for charging the capacitor, and

(4) attaching 3 ball-shaped smaller capacitors to the bottom of the pyramidal-shaped capacitor; and

(5) providing means to extend or retract the ball-shaped capacitors from the pyramidal-shaped capacitor, so DC electrostatic energy is converted into propulsive force by the action of the first capacitor and the 3 ball-shaped smaller capacitors provide directional control.

Inertial forces pose great obstacles to improving the performance of current propulsion systems. The most significant aspect of this type of propulsion would be the loss of inertia during acceleration. The passengers of such craft would feel no forces acting upon their bodies even if the craft achieved enormous accelerations.

This overall design is suitable for the development of a wide range of transportation vehicles, from automobile-type to aircraft and potentially to spacecraft. With such technology, we could eliminate a major factor in environmental pollution which place a great stress on our ecosystem. In the United States, transportation vehicles produce 66% of the greenhouse gases.

The subject invention offers a solution by providing a renewable, non-polluting electricity generation method as well as an electricity-based transportation method capable of levitation and flight.

The following Example illustrates the features and advantages of the subject invention. Accordingly, it is to be understood that the description in this disclosure is to facilitate comprehension of the invention and should not be construed to limit the scope thereof as persons skilled in the art can, in light of this disclosure, generate additional embodiments without exceeding the scope or departing from the spirit of the claimed invention.

EXAMPLE 1

Demonstration of the pyramid generator: For the experiments, I have selected a one-foot base length foam pyramid from a pyramid vendor (The Pyramid Project, Ft. Wayne, Ind.). The outside of the pyramid was covered with aluminum foil. The pyramid was placed on a 2'×2'insulating polyethylene platform equipped with an adjustable height 2'×2'size aluminum top plate, 1/16" thick. The height of the aluminum plate was adjusted as needed and a gap of 1 1/4" between the plate and the tip of the pyramid was used in the experiments. In some experiments, an aluminum pyramid was used with a wall thickness of 1/16".

A high voltage (HV) CRT power source producing 30 kV DC was taken from a color monitor. I have assumed that an actual energy-producing pyramid should be relatively high in order to obtain a large voltage drop from its tip to the ground. Therefore, assuming a height of 100–150 m for a life-size pyramid and a voltage drop of 200–300 V/m near the surface of the Earth, the 30 kV is in the range of the voltage-drop expected for the height of a life size pyramid.

The positive pole was attached to the top aluminum plate. This simulated the positive charge of the atmosphere. One corner of the pyramid was attached to the negative pole of the high voltage power source, while the opposite corner of the pyramid was grounded. This setup served as a model for the electrostatic field distribution around a potential life-sized pyramid. As controls, either a 1'×1' sheet of aluminum foil or an aluminum foil-covered box, having the main dimensions of the test pyramid (1'×1'×7 5/8"), was used as a negative pole. The detector coils were made by winding up a 24 gauge enamel-coated magnet wire (20 turns, approximately 8 cm in diameter). A Tektronix high-frequency oscilloscope, Model no. 2236 was used for signal acquisition and analysis.

The first sets of experiments were control measurements with a box of the same height and base length as the test pyramid. The detector coil was placed on the top of the box. Measurements were taken with or without the high voltage applied. One corner of the box was attached to the HV power source (negative pole) and the opposite corner to the ground.

The same arrangement was used for the flat square (1'×1') foil. The peak-to-peak signal amplitude for the box was 8 mV and the signal frequency was 2 MHz. For the flat foil sheet, the signal amplitude was 12 mV with a frequency of 1.43 MHz. The signal form was of a decaying sine wave.

When high voltage was applied to these shapes, signal amplitude of 14 mV was obtained for the flat sheet and of 16 mV for the box. The signal frequency was 1.54 MHz for the flat sheet and 2 MHz for the box. The waveforms were of decaying sine waves in all these experiments.

When the pyramid was tested without HV, the peak-to-peak signal amplitude was measured at 60 mV with a frequency of 2 MHz. When the high voltage was applied, the signal amplitude increased up to 180–200 mV, while the frequency remained at 2 MHz. The pyramid produced signal intensity significantly higher than the controls. The signal is regularly repeating, clock-like in nature (FIG. **2**). When a metal (aluminum) pyramid of the same size (wall thickness 1⁄16" inch) was tested in the same high voltage field using the same detection coil, a voltage of 1–1.5 V was detected at the frequency of 2 MHz.

To collect energy from the coil, a bridge rectifier (1000 V peak voltage at 6 A) was attached to the leads of the coil. The rectified current was fed into a capacitor (1500 μF, 250 V DC max.), and a direct current of 45 V was obtained. This has demonstrated a simple method to convert electrostatic energy into a continuous direct current. An 8-turn coil having an output of 200–300 V AC (peak-to-peak) was also used for energy conversion. The rectified current from the 8-turn coil powered a 0.186 W light bulb (FIG. **3**). The bridge rectifier is optimally made of fast-recovery diodes.

Even in the absence of an externally applied voltage, current is always present in the circuit. Charge builds up in the capacitor and 1 V was obtained overnight using the 20-turn coil setup. Over 48 h, a voltage of 5 V was measured. Faraday shielding practically abolished the phenomenon.

The preferred shape of the pyramid as a charge collector was again demonstrated in further experiments using the 8-turn coil-bridge rectifier-capacitor (1,500 μF) assembly placed on the 1 ft base length aluminum pyramid. A same volume and height aluminum box was used as control. Charging times of 1–2 h were used under fair weather conditions. For the pyramid, 550 mV was measured on the capacitor while on the box 100 mV was obtained. This demonstrated the superiority of the pyramidal shape in capturing atmospheric electrostatic energy. It also demonstrated that we could tap into the electrostatic field of the atmosphere and draw electric energy. For the collection of energy, a battery could substitute for the capacitor.

I claim:

1. A method for converting DC electrostatic energy into usable electrical energy, the method comprising the steps of:

(a) providing a first capacitor of pyramidal shape, the first capacitor capable of being charged by and storing DC electrostatic energy;

(b) placing an insulated coil on the surface of the first capacitor, the coil having leads;

(c) attaching a rectifier to the leads of the coil, the rectifier having leads; and

(d) attaching a second capacitor or battery to the leads of the rectifier so that DC electrostatic energy stored by the capacitor of pyramidal shape is converted into usable electric energy.

2. The method of claim **1** wherein a clock-like signal is detected from the leads of the coil.

3. The method of claim **1** wherein the signal is rectified.

4. The method of claim **1** wherein the signal is pooled in the second capacitor.

5. The method of claim **1** wherein the rectified signal is pooled in the battery.

6. A method for converting DC electrostatic energy into propulsive force comprising the steps of:

(a) providing a first capacitor of pyramidal shape, the first capacitor capable of being charged by and storing DC electrostatic energy;

(b) placing an insulated conductive tip on the point of the first capacitor;

(c) providing a static generator for charging the first capacitor;

(d) attaching 3 ball-shaped smaller second, third, and fourth capacitors to the bottom of the pyramidal-shaped first capacitor; and

(e) providing means to extend or retract the ball-shaped second, third, and fourth capacitors from the pyramidal-shaped first capacitor, so DC electrostatic energy stored by the first capacitor of pyramidal shape is converted into propulsive force by the action of the first capacitor and the 3 ball-shaped smaller second, third, and fourth capacitors provide directional control.

7. The method of claim **6** wherein the energy stored in the pyramidal first capacitor is used for the propulsion of a vehicle.

8. The method of claim **6** wherein the pyramidal first capacitor is negatively charged.

9. The method of claim **6** wherein the insulated conductive tip placed on the point of the pyramidal first capacitor is positively charged.

10. The method of claim **6** wherein the ball-shaped second, third, and fourth capacitors provide lateral movement control for the vehicle.

11. The method of claim **6** wherein the ball-shaped second, third, and fourth capacitors serve as landing pods.

12. The method of claim **6** wherein the ball-shaped second, third, and fourth capacitors are retracted after take-off.

13. The method of claim **10** wherein the ball-shaped second, third, and fourth capacitors are charged for lateral directional control after takeoff.

(57) **ABSTRACT**

A pyramid electric generator for harvesting the vibrational energies of Earth's atomic oscillators according to the present invention comprises: (1) an antenna/waveguide that is geometrically optimized; (2) a secondary coil wound with an insulated conductor on a nonconductive coil form, the coil being attached electrically to the conducting surface of the antenna/waveguide such that the secondary coil is attached near the point at which the electric field contacts the antenna/waveguide; (3) the antenna/waveguide connected with the secondary coil serving as a quasi-capacitive series element to provide a specific resonant frequency; and (4) a primary coil of a few turns wound around the secondary coil, the secondary coil being positioned coaxially within the primary coil and acting as a resonant step-up transformer winding, inductively coupled with the primary coil. The generator resonantly couples into specific frequencies of Earth's atomic oscillators and extracts electric energy therefrom.

PYRAMID ELECTRIC GENERATOR

CROSS-REFERENCES

This application is a continuation-in-part of PCT Application Ser. No. PCT/US07/69804 by Grandics, entitled "An Electric Power Converter for Extraction of Atmospheric Electrical Energy," designating the United States and filed on May 25, 2007, which in turn claimed priority from U.S. Provisional Application Ser. No. 60/818,360 by Grandics, also entitled "An Electric Power Converter for Extraction of Atmospheric Electrical Energy," and filed on Jul. 3, 2006. The specifications of these two applications are incorporated herein in their entirety by this reference.

BACKGROUND OF THE INVENTION

This invention relates to the generation of electrical power by drawing energy from Earth's electric field. Earth represents a resonant system in which both atmospheric and telluric electrical processes can be harvested. In U.S. Pat. No. 6,974,110, we have provided an apparatus and method for converting the electrostatic potential energy of Earth's atmosphere. The present invention aims to provide an electric generator that, in addition to tapping atmospheric electric processes, extracts electrical power from the vibrational energy of atomic oscillators by a novel resonant coupling method.

SUMMARY OF THE INVENTION

An electrical generator according to the present invention provides a new method of tapping Earth's electric energy field.

One aspect of the present invention is an apparatus for capturing both atmospheric and telluric electric energies, comprising:

(1) an antenna/waveguide that is geometrically optimized, having a conducting surface;

(2) a primary coil wound with a conductor over a secondary coil, the coil being attached electrically to a driver operating in the LF radio band; and

(3) a secondary coil smaller in diameter than the primary coil having a greater length and a greater number of turns than the primary coil and having a first lead and a second lead, the secondary coil being positioned coaxially within the first coil and acting as a resonant step-up transformer winding, inductively coupled with the primary coil and an external capacitor connected in parallel with the secondary coil to provide a specific resonant frequency; or

(4) a secondary coil smaller in diameter than the primary coil, having a greater length and a greater number of turns than the primary coil and having a first lead and a second lead, the secondary coil being positioned coaxially within the first coil and acting as a resonant step-up transformer winding, inductively coupled with the primary coil and connected with the antenna/waveguide serving as a quasi-capacitive series element to provide a specific resonant frequency;

wherein the conducting surface of the antenna/waveguide is configured such that the secondary coil is connected near the point at which the electric field contacts the antenna/waveguide;

wherein the generator absorbs electromagnetic impulses from Earth's electric field; and wherein a high voltage sinusoidal waveform is generated in the secondary coil representing harvested atmospheric and telluric electrical energy and measurable on the leads of the secondary coil.

Preferably, the antenna/waveguide is of pyramidal shape. When the antenna/waveguide is of pyramidal shape, the secondary coil is preferably connected near or at the apex of the antenna/waveguide.

Another aspect of the present invention is an electric generator for harvesting the electric emissions of atomic oscillations comprising an oscillator. Typically, the oscillator operates in the LF or ELF bands.

Typically, in this aspect of the present invention, the generator comprises:

(1) a primary coil wound with a conductor over a secondary coil, the coil being connected electrically to a driver operating in the LF or ELF bands; and

(2) a secondary coil of smaller diameter than the primary coil having a greater length and a greater number of turns than the primary coil, the secondary coil being positioned coaxially within the first coil and acting as a resonant step-up transformer winding inductively coupled with the primary;

wherein said resonant step-up transformer's output voltage exceeds 500 V_{RMS};

wherein the electric generator attracts impulses from Earth's electric oscillations; and

wherein the attracted energy manifests as high voltage sinusoidal waveforms representing harvested electric energy of atomic oscillations in the secondary coil and measurable on leads of the secondary coil.

Another aspect of the present invention is a method of tapping Earth's electric energy field, comprising these steps:

(1) positioning an electric generator according to the present invention as described above, so that it is exposed to a source of atmospheric and telluric electric energy; and

(2) producing a high-voltage sinusoidal signal representing electrical energy harvested by the operation of the generator.

BRIEF DESCRIPTION OF THE DRAWINGS

The following invention will be better understood with reference to the specification, appended claims, and accompanying drawings, where:

FIG. **1** is a graph showing the formation of electric vortices across and around the pyramid.

FIG. **2** is a graph showing the circuit diagram of the pyramid generator.

FIG. **3** is a graph showing the power in the secondary coil vs. the power in the primary coil.

FIG. **4** is a graph showing the power in the secondary coil vs. the apex voltage on the pyramid.

FIG. **5** is a graph showing the circuit diagram of the pyramid generator with the measurement points.

DETAILED DESCRIPTION OF THE INVENTION

One aspect of the present invention is an electric generator for attracting the electric emissions of atomic oscillations by the use of high voltage, to harvest electric energy therefrom.

One embodiment of this aspect of the invention is an apparatus for capturing atmospheric and telluric electric energies by harvesting the energies of atomic oscillators, comprising:

(1) an antenna/waveguide that is geometrically optimized, having a conducting surface;

(2) a primary coil wound with an insulated conductor, the coil being connected to an AC or AC-DC driver; and

(3) a secondary coil smaller in diameter than the primary coil, having a greater length and a greater number of turns than the primary coil and having a first lead and a second lead, the secondary coil being positioned coaxially within the first coil and acting as a resonant step-up transformer winding,

inductively coupled with the first coil; and an external capacitor connected in parallel with the secondary coil to provide a specific resonant frequency; or

(4) a secondary coil smaller in diameter than the primary coil, having a greater length and a greater number of turns than the primary coil and having a first lead and a second lead, the secondary coil being positioned coaxially within the first coil and acting as a resonant step-up transformer winding, inductively coupled with the first coil and connected with the antenna/waveguide serving as a quasi-capacitive series element to provide a specific resonant frequency, with the secondary coil attached near the point at which the electric field contacts the antenna/waveguide;

wherein the generator absorbs electromagnetic impulses from Earth's electric field; and

wherein a high-voltage, sinusoidal waveform is generated in the secondary coil representing harvested atmospheric and telluric electrical energy and measurable on leads of the secondary coil.

Preferably, the antenna/waveguide is of pyramidal shape. However, any geometric shape can be used for the antenna/waveguide. When it is of pyramidal shape, the secondary coil is preferably connected near or at the apex of the antenna/waveguide. The shape and size of the antenna/waveguide can be optimized depending on the intended use of the generator. Preferably, the antenna/waveguide exhibits ratios of pi and the Fibonacci number (phi).

Typically, the generator further comprises an insulated base on which the antenna/waveguide is placed. The size and shape of the insulated base can also be optimized, depending on the intended use of the generator. The second lead of the secondary coil is typically connected to earth ground.

Typically, the output of the secondary coil is harvested. This can be done by connecting to a rectifier-capacitor-load resistance, or by a third coil inductively coupled with the secondary coil. In one alternative, the output of the secondary coil is coupled to a load for drawing power from the generator. The optimal circuit can be selected by one of ordinary skill in the art to optimize power extraction. The load draws power from the generator. The load can be a resistor, a rectifier or a storage capacitor powering a DC load. Typically, the antenna/waveguide is at a high voltage during the operation of the generator. Typically, the antenna/waveguide voltage is greater than 500 V_{RMS}. The antenna/waveguide can be connected to an oscillator. The oscillator can comprise a resonant step-up transformer.

Typically, the antenna/waveguide is in resonance with the secondary coil. Typically, the primary coil is inductively coupled to the secondary coil.

Typically, the antenna/waveguide is positioned in a generally north-south direction to tap atmospheric and telluric electric energy. In this arrangement, when the antenna/waveguide is of pyramidal shape, the height of the pyramid can be from about 0.5 m to about 1000 m, more typically, from about 0.50 m to about 150 m. The optimal pyramid size is a function of the power requirements. However, a pyramid can be built even 1 km in height. Typically, the base surface area of the pyramid ranges from about 0.25 m^2 to about 1,000,000 m^2; more typically, from about 0.25 m^2 to about 25,000 m^2. Naturally, other heights and base surface areas can be used for particular applications. The numbers of sides can also vary. When the pyramid is small (e.g., 6-feet base length described in this application), there is an insufficient atmospheric potential on its apex to trigger the attraction of power. In such event, an AC or AC-DC driver is necessary to bring the pyramid to the electric potential necessary. A suitable voltage is typically greater than 500 V_{RMS}.

In one alternative, the primary coil is wound with a conductor over the secondary coil, the primary coil being connected electrically to a driver operating in the LF or ELF bands.

Another aspect of the present invention is an electric generator for harvesting the electric emissions of atomic oscillations comprising an oscillator. Typically, the oscillator operates in the LF or ELF bands.

Typically, in this aspect of the present invention, the generator comprises:

(1) a primary coil wound with a conductor over a secondary coil, the coil being connected electrically to a driver operating in the LF or ELF bands; and

(2) a secondary coil of smaller diameter than the primary coil having a greater length and a greater number of turns than the primary coil, the secondary coil being positioned coaxially within the first coil and acting as a resonant step-up transformer winding inductively coupled with the primary;

wherein said resonant step-up transformer's output voltage exceeds 500 V_{RMS};

wherein the electric generator attracts impulses from Earth's electric oscillations; and

wherein the attracted energy manifests as high voltage sinusoidal waveforms representing harvested electric energy of atomic oscillations in the secondary coil and measurable on leads of the secondary coil.

In this alternative, the output of the secondary coil can be coupled to a load for drawing power from the generator.

Another aspect of the invention is a method of tapping Earth's electric energy based on the following concepts:

(1) utilizing a pyramidal antenna/waveguide designed based on the ratios of pi and phi;

(2) using the antenna/waveguide to absorb and focus specific frequencies of Earth's electric field;

(3) positioning a resonant coil system connected to said antenna/waveguide near or at its apex according to the present invention; and

(4) generating a high-voltage sinusoidal signal, representing harvested atmospheric and telluric electrical energy, by the operation of the coil system.

Typically, in this method, the method comprises the steps of:

(1) positioning an electric generator according to the present invention as described above such that it is exposed to Earth's electric oscillations; and

(2) generating a high voltage sinusoidal signal representing harvested electric energy of atomic oscillators by the operation of the generator.

Typically, the harvested electric energy can be fed into a power grid for distribution, but smaller units capable of distributed power generation or for use as stand-alone generators are also feasible by the concept of this invention.

The invention is described by the following Example. This Example is included for illustrative purposes only and is not intended to limit the invention.

EXAMPLE

We have introduced a new theory of space, energy and matter that predicted that electromagnetic interaction propagates through a carrier medium called the space lattice that is made up of pulsating, phi-based spiral vortices (STAR), the excitation of which generates propagating sinusoidal lines of force across the space lattice recorded as electromagnetic waves by our instruments [1,2]. We have also predicted that natural pressure gradients exist within the space lattice that can be used for power generation by inserting a capacitor into such gradient. Furthermore, we proposed that a pyramid-shaped capacitor is an optimally shaped device for tapping the energy gradient of the space lattice that manifests in the form of an electrical potential gradient in Earth's atmosphere. This was demonstrated subsequently [3-5]. We also found that the pyramid-shaped capacitor design should be based on ratios of pi and phi [5] because electrical energy propagates along a phi-based spiral [6].

We suggested that elemental particles are composed of STAR oscillators that make up the space lattice by electromagnetic compression of its elemental cubes into pulsating conical/vortexual subunits that form the basis for all particles of matter [1,2]. We proposed that atomic and subatomic oscillators could vibrate in a very wide frequency range from sub-acoustic to extremely high EM frequencies [1,2]. This does not mean that material bodies can take or maintain a physical form at any energy level, but this allows the recycling of atoms into the space lattice as part of their natural evolution [2,6].

Atomic oscillators are constantly in motion, and such motion is electric because all motion and energy is fundamentally electric [2,6]. It is known that atomic bodies constantly exchange electric energy. Such energy flow can be harvested when the spiral physical nature of electric waves is recognized. Russell observed that energy always moves during its generative cycle in spirals towards the higher potential [7]; therefore, we reasoned that an "attractor" of high electric potential must be provided to pull in the random electromagnetic emissions of atomic oscillators. The "attractor" must function as a phi-based antenna/waveguide to focus the phi-based electric emissions of atomic bodies into the apex of a vortex, the same method Nature uses for power multiplication [6,7]. Therefore, a phi-based pyramidal antenna/waveguide must be at a high voltage in order to perform its attractor function.

As all material manifestations are tonal [8], acoustic vibrations are always generated during the oscillations of atomic bodies, even though they are inaudible most of the time. Sometimes, however, they are detected; one such example is Earth's hum [9-11]. Earth's solid mass and its atmosphere represent a coupled resonant system, and is therefore our expanded target power source. Acoustic waves are also electrical [8] and can be harvested. To achieve this goal, the geometrically optimized pyramidal antenna/waveguide must be connected to an oscillator that operates at a high voltage and is tuned to a suitably selected frequency.

The appropriate resonant frequency is dictated by practical considerations. Atomic oscillators can vibrate in a very wide frequency range [1,2,6-8] but short wavelength radiations are readily re-absorbed by atoms and are rapidly attenuated; therefore, long wavelength electromagnetic emissions must be targeted. The operation of the pyramid generator is feasible in the ELF to the LF range. As electric radiation propagates in a vortex [2,6-8], the emitted electric vortex over the pyramidal antenna (FIG. **1**) increases its "size," and so it is capable of funneling atmospheric electromagnetic emissions of the same frequency back into the antenna/receiver. Thus, the pyramid electric generator could capture the energy emitted by both telluric and atmospheric atomic oscillators. We have tested these assumptions and demonstrated the basic principles of an electric generator.

Methods and Results

In our previous papers, we reported that a pyramid-shaped capacitor/antenna converts atmospheric electrostatic discharge impulses (ESD) into a periodic high-frequency signal that can be detected in an insulated coil placed in proximity of the capacitor [3,4]. Here, we report on further developments including a new design for the resonant coil system and an expanded range of energy sources targeted. A Tektronix TPS 2024 digital oscilloscope was used for signal acquisition and analysis, and Tektronix A503 current amplifiers were used with the Tektronix A6302 and A6303 probes for current measurement. High voltage was measured using a Tektronix P6015 probe. An ENI-1140LA amplifier was used to activate the primary coil of the resonant coil system at the selected frequency.

For the experiments, we used a geometrically optimized pyramid-shaped antenna/waveguide [3-5]. The pyramid expressed ratios of pi and phi and was approximately a 1:125 scaled down replica of the Great Pyramid of Giza (GPF), 6 feet base length. The pyramid was built of a wooden frame and covered with triangular copper sheets of 0.66 mm thickness on its sides that were electrically connected. It was placed on an insulating base and positioned in the general North-South direction.

The secondary coil (coil **2**) was wound with a 20 AWG insulated magnet wire with a monofilament nylon spacer (0.06 mm diameter) between the turns on a fiberglass cylindrical coil form, and connected to the conducting surface of the pyramid near its apex. Thus, the secondary coil was connected with the pyramidal antenna/waveguide as a quasi-capacitive series element to provide a specific resonant frequency with coupling to the surrounding electromagnetic environment. The other lead of coil **2** was grounded (FIG. **2**). The purpose of the monofilament spacer was to reduce inter-winding capacitance in coil **2** by increasing distance between wire turns of the coil.

A primary coil of larger diameter (coil **1**) was wound on or near the lower cylindrical volume of coil **2** with the lead connected to earth ground, and served as a driver coil inductively coupled with the secondary (coil **2**). The secondary was isolated from the primary by layers of silicon rubber and foam. The two coils make a resonant step-up transformer, the parameters of which are shown in Table 1.

TABLE 1

Physical and Electrical Parameters of the Resonant Transformer	
Secondary turns of wire	840 turns
Height	0.85 m
Wire diameter	0.00081 m
Primary turns of wire	5 + 9/10 turns
Height	0.21 m
Wire diameter	¼" O.D. copper pipe with .030" wall thickness
Primary	
Inductance	98 μH
Resistance	0.118 ohms
Secondary	
Inductance	24.16 mH
Resistance	24.42 ohms

Winding ratio	1:143
Mutual inductance	6.13 mH

In the experiment; the controlled variable was the voltage, which was increased in steps until the maximum voltage in the secondary (permitted by circuit components and test equipment) was achieved for the given resonant frequency. The objective was to "drive the atmosphere" by radiating a high voltage (~20 kV p-p), LF (40-120 kHz) signal developed by the high ratio step-up transformer and fed by a powerful signal generator at a resonant frequency either with an L-C resonant secondary coil, or a resonance determined by the pyramid as a quasi-capacitive series element connected to the secondary coil of the transformer and radiating to the local atmosphere. The data are shown in Table 2.

The experimental data are shown in Table 2. The current readings were also confirmed by using "current sensing" resistors (not shown). A apparent power gain of nearly 100-fold was achieved in the secondary coil relative to input power in the primary coil, and a linear increase of power in the secondary coil with the increase of input power into the primary coil (FIG. **3**). The power in the secondary coil exponentially increases with the pyramid apex voltage (FIG. **4**).

A load may be connected to coil **2** to draw power from the system. The load may also be connected via a tertiary coil inductively coupled to the secondary coil. The load may be a resistor, a rectifier or storage capacitor powering a DC load.

A graphic representation of the test system is shown in FIG. **5**. The pyramidal antenna/waveguide, placed on an insulating base, is coupled to the surrounding electromagnetic environment and serves as an antenna/waveguide for the concentration of atmospheric and telluric electromagnetic oscillations at resonance frequency. As the flow of electric energy is always balanced [6], two vortices may cross the pyramidal antenna: one from the direction of the ground concentrating into its apex, and another one from its apex propagating into the atmosphere (FIG. **1**). The atmospheric electric vortex possibly acts as an ionic antenna pulling in EM radiations from a large atmospheric domain. In FIG. **5**, the antenna/waveguide **10** is attached to a coil **12**. To drive the system, a RF generator **14** is connected to a signal amplifier **16**. The signal amplifier **16** is also connected to an uninterruptible power supply (UPS) **18** through a sinewave generator **20** and a frequency counter **22**. Outputs from the sinewave generator **20** and frequency counter **22** are also connected to a first current amplifier **24**. The output from the antenna/waveguide **10** and coil **12** are also connected to a second current amplifier **26**. The sinewave generator **20**, frequency counter **22**, first current amplifier **24**, and second current amplifier **26** are connected to a digital oscilloscope **28**. Outputs from the antenna/waveguide **10** and coil **12** are also connected to the digital oscilloscope **28**. A laptop computer **30** controls the sinewave generator **20** and frequency counter **22**.

The pyramid's apex is attached to a coil of high turn number (FIGS. **2** & **4**). This secondary coil wound on a nonconductive coil form serves as a step-up transformer, and forms a resonant circuit with the pyramid that acts as a quasi-capacitive series element. The secondary coil is activated by a signal from an RF generator via a primary coil of a few turn numbers inductively coupled to coil **2**. The measurement points are also indicated, displaying the positions of voltage and current probes. The data are captured by a digital oscilloscope and recorded on a laptop computer.

Discussion

This invention demonstrates a novel approach to harvest Earth's electric energy. The masses of Earth and its atmosphere represent a coupled resonant system that is continually electrified by solar radiation. We have found that a pyramidal antenna designed based on the ratios of phi and pi is optimal for the capture of atmospheric electrostatic discharge (ESD) impulses [3-5]. Atmospheric ESD is a product of solar radiation and is a wide bandwidth phenomenon. The pyramid as a wideband, non-resonant antenna is uniquely adapted to harvest the energy of atmospheric ESD.

This invention also points out an additional energizing mechanism at work during the operation of the pyramid electric generator. The observation is derived from our theory on energy, matter and space [1,2] as well as that of Russell [6,7]. Both Russell and we observed that spiral motion is a fundamental action of matter and that the vortex is the mechanism of power multiplication in Nature. A vortex concentrates power into its apex where the highest velocity of motion, the highest pressure and the highest electric potential resides [1,2,6,7]. As electricity propagates along a pulsating phi-based spiral [6,7], a phi-based antenna/waveguide is suitable to focus its energy into the apex of a vortex inside the antenna. A phi-based pyramid is optimal for this purpose.

As atomic bodies can oscillate in a very wide frequency range [1,2,6-8], a pyramidal antenna/waveguide coupled to an oscillator that is tuned to a suitable frequency can focus the "electric noise" from Earth's atomic oscillators into the apex of the pyramid at a high voltage. Russell observed that energy moves towards the higher potential during its generative cycle [7]; therefore, it is essential that the pyramidal antenna be at a high potential. Our data corroborated this assumption.

To select a suitable frequency range, one can begin with the observation that all material manifestations are tonal [8], and that acoustic frequencies are always generated during the oscillations of atomic bodies even though they remain inaudible most of the time. Acoustic waves are also electric [8] and therefore Earth's enormous mass and its atmosphere represent a coupled resonant system that offer a vast source of power.

For practical reasons on our small pyramid, we have chosen a frequency above the audio range but below the radio frequency spectrum; our antenna was made to radiate at the target wavelength. The wavelength of the 50-120 kHz range is 6 km to 25 km, thus allowing energy to be harvested over a large atmospheric domain. As electrical energy propagates in a vortex [6,7], the emitted electric vortex (ionic antenna) over the pyramidal antenna/waveguide increases its "size" and enables it to funnel the same frequency atmospheric electromagnetic radiations back into the antenna. Thus, the pyramid electric generator captures at the selected frequency the energy emitted by Earth's atomic oscillators.

The presence of an electric (ionic) vortex was demonstrated by radar testing of the space over a 44 m tall fiberglass pyramid located near Moscow [12]. The Russians found that the large ionized column of air over the area of the vertical axis of the pyramid had a width of about 500 m and reached an altitude of 2 km. It is remarkable that this effect was induced by a nonconductive pyramid surface demonstrating a significant degree of atmospheric ionization even under fair weather conditions. Thus, a suitably sized large or an electrically activated small pyramid should open a low impedance path to higher elevations of relatively conductive atmospheric domains.

In conclusion, the total power that can be extracted from Earth's atomic oscillators must be extremely large, likely far exceeding current global electric generation capacity. In our experiment, we obtained over 7000 VA power at about 20 kV p-p pyramid voltage using a 6 feet base length pyramid. This power is nearly 100 times greater than the power necessary to drive the pyramid to the required operating voltage. By constructing the pyramid generator from dedicated high voltage components and using higher drive voltages, a significant increase in power output is envisioned. The power extraction will also be enhanced by further optimization of the designs of both the pyramid and the coil system.

The power output will also increase by employing larger pyramid structures and coils. As voltage is the primary factor in attracting power into the system, the necessary voltage can be provided by the vertical atmospheric potential on a tall pyramid. Since the atmospheric vertical potential gradient could go as high as 1200 V/m near Earth's surface under fair weather conditions [13], a pyramid height of 80-150 m seems sufficient to provide the apex voltage for a self-sustaining power generator. As the pyramid scales up volumetrically, a power generator pyramid of the size range of the GPG could likely have an output in the hundreds to thousands of megawatts range. Groups of several pyramid electric generators could be placed within specific geographical areas, thus combining their energy harvesting capacity.

ADVANTAGES OF THE INVENTION

The present invention provides a new method of tapping Earth's electric energy and providing usable power that can be fed into a power grid or supplied by stand-alone power generators. It does so without the need for mechanical energy or the consumption of fossil fuel or the long-term risks associated with power generated by nuclear fission, including the risk of diversion of fissionable material to terrorist aims or the risk posed by the required long-term storage of spent nuclear fuel. Devices according to the present invention can operate virtually continuously with little to no maintenance.

With respect to ranges of values, the invention encompasses each intervening value between the upper and lower limits of the range to at least a tenth of the lower limit's unit, unless the context clearly indicates otherwise. Moreover, the invention encompasses any other stated intervening values and ranges including either or both of the upper and lower limits of the range, unless specifically excluded from the stated range.

Unless defined otherwise, the meanings of all technical and scientific terms used herein are those commonly understood by one of ordinary skill in the art to which this invention belongs. One of ordinary skill in the art will also appreciate that any methods and materials similar or equivalent to those described herein can also be used to practice or test this invention.

The publications and patents discussed herein are provided solely for their disclosure prior to the filing date of the present application. Nothing herein is to be construed as an admission that the present invention is not entitled to antedate such publication by virtue of prior invention. Further the dates of publication provided may be different from the actual publication dates which may need to be independently confirmed.

All the publications cited are incorporated herein by reference in their entireties, including all published patents, patent applications, and literature references, as well as those publications that have been incorporated in those published documents. However, to the extent that any publication incorporated herein by reference refers to information to be published, applicants do not admit that any such information published after the filing date of this application is to be considered prior art.

As used in this specification and in the appended claims, the singular forms include the plural forms. For example the terms "a," "an," and "the" include plural references unless the content clearly dictates otherwise. Additionally, the term "at least" preceding a series of elements is to be understood as referring to every element in the series. The inventions illustratively described herein can suitably be practiced in the absence of any element or elements, limitation or limitations, not specifically disclosed herein. Thus, for example, the terms "comprising," "including," "containing," etc. shall be read expansively and without limitation. Additionally, the terms and expressions employed herein have been used as terms of description and not of limitation, and there is no intention in the use of such terms and expressions of excluding any equivalents of the future shown and described or any portion thereof, and it is recognized that various modifications are possible within the scope of the invention claimed. Thus, it should be understood that although the present invention has been specifically disclosed by preferred embodiments and optional features, modification and variation of the inventions herein disclosed can be resorted to by those skilled in the art, and that such modifications and variations are considered to be within the scope of the inventions disclosed herein. The inventions have been described broadly and generically herein. Each of the narrower species and subgeneric groupings falling within the scope of the generic disclosure also form part of these inventions. This includes the generic description of each invention with a proviso or negative limitation removing any subject matter from the genus, regardless of whether or not the excised materials specifically resided therein. In addition, where features or aspects of an invention are described in terms of the Markush group, those schooled in the art will recognize that the invention is also thereby described in terms of any individual member or subgroup of members of the Markush group. It is also to be understood that the above description is intended to be illustrative and not restrictive. Many embodiments will be apparent to those of in the art upon reviewing the above description. The scope of the invention should therefore, be determined not with reference to the above description, but should instead be determined with reference to the appended claims, along with the full scope of equivalents to which such claims are entitled. Those skilled in the art will recognize, or will be able to ascertain using no more than routine experimentation, many equivalents to the specific embodiments of the invention described. Such equivalents are intended to be encompassed by the following claims.

I claim:

1. An electric generator for harvesting the energies of atomic oscillators comprising:

(a) an antenna/waveguide that is geometrically optimized having a conducting surface;

(b) a primary coil wound with an insulated conductor over a secondary coil, the coil being connected to an AC or AC-DC driver; and

(c) a secondary coil of smaller diameter than the primary coil having a greater length and a greater number of turns than the primary coil and having a first lead and a second lead, the secondary coil being positioned coaxially within the first coil and acting as a resonant step-up transformer winding inductively coupled with the primary and an external capacitor connected in parallel with the secondary coil to provide a specific resonant frequency; or

(d) a secondary coil of smaller diameter than the primary coil having a greater length and a greater number of turns than the primary coil and having a first lead and a second lead, the secondary coil being positioned coaxially within the first coil and acting as a resonant step-up transformer winding inductively coupled with the primary and connected with the antenna/waveguide serving as a quasi-capacitive series element to provide a specific resonant frequency;

wherein the conducting surface of the antenna/waveguide is configured such that the secondary coil is attached near the point at which the electric field contacts the antenna/waveguide;

wherein the generator absorbs impulses from Earth's electric oscillations; and wherein the attracted energy manifests as high voltage sinusoidal waveforms in the secondary coil, representing harvested atmospheric and telluric electrical energy and measurable on the leads of the secondary coil.

2. The electric generator of claim **1**, wherein a suitable voltage is greater than 500 V_{RMS}.

3. The electric generator of claim **1**, wherein the antenna/waveguide is designed based on ratios of pi and phi.

4. The electric generator of claim **1**, wherein the antenna/waveguide is of pyramidal shape.

5. The electric generator of claim **1**, wherein the antenna/waveguide is placed on an insulated base.

6. The electric generator of claim **1**, wherein the antenna/waveguide is at a high voltage during the operation of the generator.

7. The electric generator of claim **6**, wherein the antenna/waveguide voltage is greater than 500 V_{RMS}.

8. The electric generator of claim **1**, wherein the antenna/waveguide is connected to an oscillator.

9. The electric generator of claim **8**, wherein the oscillator comprises a resonant step-up transformer.

10. The electric generator of claim **4**, wherein the secondary coil of the transformer is connected near the apex of the antenna/waveguide.

11. The electric generator of claim **1** wherein the second lead of the secondary coil is connected to earth ground.

12. The electric generator of claim **1** wherein the primary coil is wound with a conductor over the secondary coil, the primary coil being connected electrically to a driver operating in the LF or ELF bands.

13. The electric generator of claim **1**, wherein the primary coil is inductively coupled to the secondary coil.

14. An electric generator for harvesting the electric emissions of atomic oscillations of claim **1** comprising an oscillator.

15. The electric generator of claim **14**, wherein said oscillator operates in the LF or ELF bands.

16. The electric generator of claim **14** wherein the generator comprises:

(a) a primary coil wound with a conductor over a secondary coil, the coil being connected electrically to a driver operating in the LF or ELF bands; and

(b) a secondary coil of smaller diameter than the primary coil having a greater length and a greater number of turns than the primary coil, the secondary coil being positioned coaxially within the first coil and acting as a resonant step-up transformer winding inductively coupled with the primary; wherein said resonant step-up transformer's output voltage exceeds 500V_{RMS};

wherein the electric generator attracts impulses from Earth's electric oscillations; and wherein the attracted energy manifests as high voltage sinusoidal waveforms representing harvested electric energy of atomic oscillations in the secondary coil and measurable on leads of the secondary coil.

17. The electric generator of claim **4**, wherein the height of the pyramidal electric generator is from about 0.50 m to about 1000 m.

18. The electric generator of claim **4**, wherein the base surface area of the pyramid is from about 0.25 m^2 to about 1,000,000 m^2.

19. The electric generator of claim **1**, wherein the generator is positioned in a generally north-south direction.

(57) **ABSTRACT**

A charged particle induction apparatus and method comprising a high power light emitting means, such as a laser array, in operable communication with a high energy output means to accomplish initiation of at least two concentric plasma channels in atmosphere extending from the Earth's surface to the charge-rich upper atmosphere, including the ionosphere, for the transmission of charged particles therethrough to ground using the surrounding atmosphere as an insulator. The transmitted energy is drawn down (due to an artificially created potential) through the conductive plasma channels to collection means.

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] The present application is a continuation of U.S. patent application Ser. No. 14/197,698, filed Mar. 5, 2014; which is a continuation of U.S. patent application Ser. No. 12/917,447, filed Nov. 1, 2010 (now U.S. Pat. No. 8,693,160) which claims the benefit of U.S. Provisional Application Ser. No. 61/280,131, filed Oct. 31, 2009; all of which are hereby incorporated by reference herein in their entirety, including any figures, tables, or drawings.

FIELD OF THE INVENTION

[0002] The present invention relates to the transmission of ionospheric energy through at least two "ionosphere-to-ground" coaxial laser-induced plasma channels formed through the Earth's atmosphere. As used herein, the term "ionospheric energy" means charged particles, namely ions and electrons, in the ionosphere. As used herein, the term "channel" means a conduit having walls comprised of ionized or partially ionized gas, the channel being substantially ring-shaped in cross-section, the walls serving as the conductive path through which charged particles are induced to ground.

BACKGROUND OF THE INVENTION

[0003] The need to develop alternative clean renewable energy supplies is becoming critical. Problems of climate change and global warming due to carbon emissions are becoming an accepted fact. The dramatic rise in the cost of petro-chemical energy is due to decreased supplies and increase in world demand. There is increasing political instability of regions of the world that have large oil supplies. There are geo-political and economic ramifications of being dependent on imported energy or on being economically dependent on the export of energy from dwindling energy reserves.

[0004] Heretofore, space solar power has been considered as an alternative clean energy source. Space solar power is clean, inexhaustible, available 24 hours a day, and has the potential to generate as much energy as terrestrial power plants. However, because of the filtering effect of the Earth's atmospheric gases (air acts as an insulator), and for other reasons such as reflection and absorption, only a fraction of solar energy in any given area reaches Earth. The average solar power per unit area outside Earth's atmosphere during any given time period is about 136% that available on Earth's surface during direct sunlight (1336 W/m2). Various apparatus and methods have been considered, and some developed, to compensate for this shortcoming.

[0005] A very recent proposed solution is described in pending U.S. Patent Application No. 2009/0171477 of Neyfeh et al. which describes systems and methods that employ high-intensity lasers to set up a thin plasma sheet, also called a waveguide or "hot shell", in the atmosphere as a function of beam intensity and geometry. A laser beam can be spread and directed with physical optics to generate a thin inverted cone-shaped hot shell waveguide in the atmosphere. According to Neyfeh, the hot shell of the waveguide has a different index of refraction from that of the surrounding air layers and as such serves to internally reflect portions of the entering solar ray entering an aperture in the hot shell, toward the tip of the cone and a solar energy storage component positioned there, thus providing a virtual solar energy concentration system. The Neyfeh et al. systems and methods, therefore, endeavor to make the best of the filtered solar energy present in Earth's atmosphere.

[0006] Another proposed solution is to collect the Sun's energy in space, where it is more concentrated, via satellite-based or lunar-based collection stations. The energy must then be transmitted from the collection point in space to the Earth's surface. Since wires extending from Earth's surface to an orbiting satellite would be impractical, many space-based solar power designs have proposed the use of microwave or laser beams for wireless power transmission. The collecting station would convert solar energy into electrical energy, which would then be used to power a microwave emitter or laser directed at a collector on the Earth's surface. There are numerous technical, political, legal and economic challenges to building space solar power stations. Limitations in photovoltaic technology and the difficulty of building large structures in space are some of the issues. In the past, launch costs have been prohibitive. In addition to the relatively high costs involved with this method, other problems include cumulative radiation damage or micrometeoroid impacts.

[0007] The underlying physics of wireless power transmission resembles that of wireless communications, but with an important difference. Unlike information transfer, where the percentage of received power must be only sufficiently high enough to recover the signal, wireless power transmission places a critical emphasis on the maximum amount of possible energy transfer and conversion efficiency. Ideally, a wireless power transmission system would have the ability to transmit any amount of power to any point in space, but practical limitations such as conversion efficiencies at the source and the receiver, and disturbances in the transmission medium will always limit the performance of an implemented system.

[0008] For instance, as recently as 2006, the highest amount of energy obtained from a receiver when testing high intensity lasers to illuminate vertical multi junction solar cells developed by NASA-GRC was 23.7778 watts. One vertical multi junction solar cell was able to achieve a power density of 13.6 watts per cm^2, at a conversion efficiency of 24%. Although these experiments confirm that the VMJ technology can withstand and utilize the high intensity laser energy without damage or significant reduction in previously known conversion efficiencies, wireless power transmission via high intensity laser beaming technology is not yet ready for high order energy transfer. In short, the main limiting factors to the laser power beaming system are the conversion efficiencies of the laser (electrical to photonic) and the photovoltaic cells (photonic to electrical). Although there are a variety of photovoltaic cells on the market approaching conversion efficiencies of 40% (such as triple junction cells), these technologies cannot operate at intensities 1000 times or greater than that of the sun.

[0009] Based on the above, it is clear that there is a strong desire to harness the energy existing in both our atmosphere and beyond, but it is apparent that the various methods and apparatus designed to capture and utilize this energy source are attendant with various, problems, shortcomings and limitations.

SUMMARY OF THE INVENTION

[0010] In order to meet the need in the art, the subject invention presents an entirely different approach to "tapping" this vast energy source. At least one preferred embodiment of the invention is discussed below.

[0011] The Earth's surface—ocean and solid—and the ionosphere are highly conductive. The atmosphere conducts electricity because of the presence of positive and negative ions plus free electrons. Conductivity is poor near sea level but increases rapidly with height up to the ionosphere; also it is greater at polar latitudes than equatorial. Between ground and the Ionosphere, the atmosphere acts an insulator.

[0012] The ionosphere begins at a height of about 50 km (30 miles) above the Earth's surface, but it is most distinct and important above 80 km (50 miles). In the photochemical ionosphere (which is mostly contained within the thermosphere but also partly extends into the neighboring mesosphere), cosmic radiation of high-energy sub-atomic particles and the absorption of much of the solar ultraviolet radiation separates negative electrons from oxygen and nitrogen molecules. The ions and free electrons move rapidly under the influence of electrical forces—the ionospheric wind—and the ionosphere is highly conductive in this region. During fair weather there is an electric potential difference of 250,000 to 500,000 volts between the ionosphere and the Earth's surface, the surface being negative relative to the ionosphere. This, incidentally, gives rise to the fair weather current, which is a steady flow of electrons from the surface at about one microwatt per square meter. The subject invention is directed generally toward the exploitation of this electric potential difference, and more specifically to a system, method and apparatus for inducing a flow of charged particles from the charged upper atmosphere, including but not limited to the ionosphere, to ground through concentric laser induced plasma channels ("con-channels").

[0013] It is widely recognized that a laser beam of suitable wavelength can penetrate through a gas medium over great distances and will establish a partially ionized trail therethrough. Examples of laser systems used to produce a thin ionizing beam through the atmosphere are taught in U.S. Pat. No. 3,719,829 issued to Vaill in 1973 entitled, Laser Beam Techniques and U.S. Pat. No. 5,726,855 issued to Maourou et al. in 1998 and entitled, Apparatus and Method for Enabling the Creation of Multiple Extended Conduction Paths in the Atmosphere. Mourou et al. teaches an apparatus and method for enabling the creation of multiple laser generated extended conduction paths in the atmosphere to safely control the discharge of lightning strikes to a grounding tower. It is also well known in the art that a plasma channel has a low electrical resistance and, once formed, will permit continuous current flow if the energy source that heats the plasma can be maintained. Unlike a normal electrical conductor, the resistance (and voltage drop) across an unconfined plasma channel decreases with increasing current flow, a property called negative resistance. Because plasmas are conductive and respond to electric and magnetic fields and can be efficient sources of radiation, they are usable in numerous applications where such control is needed or when special sources of energy or radiation are required.

[0014] Unfortunately, it has been observed that a highly-ionized path will tend to lose its straight-line configuration after creation and will begin to wander transversely in serpentine configurations, which wandering, once started, will grow progressively worse. Moreover, charges carried in plasma channels tend to self constrict due to magnetic forces stemming from the current flowing through the plasma. This phenomenon is known as the "plasma pinch". Upon constricting of the charge as a result of the pinch, the current will then follow the path of least resistance to ground which is by its nature unpredictable and dangerous.

[0015] Applicant's methods and apparatus overcome these shortcomings through the creation of at least two concentric conductive paths to and from which the wandering current may "jump", in alternating fashion, thereby maintaining a continuous flow of energy in the desired direction from the ionosphere to the terrestrial target collection apparatus. According to the present invention there is thus provided a ground-to-ionosphere laser-induced conduction path of concentric plasma channels through Earth's atmosphere along which charged particles within the ionosphere may be transmitted to Earth. The term "atmosphere" as used herein means the mass of air surrounding the Earth. The term "plasma" as used herein means a combination of neutrons, ions, electrons and fields that have conductive and collective effects.

[0016] The subject apparatus more specifically comprises high power light emitting means, such as a laser array, in operable communication with a high energy output means to accomplish initiation of at least two concentric plasma channels from the Earth's surface to the ionosphere for the transmission of ionospheric energy therethrough. The path need only remain open for relatively short intervals to transmit high orders of energy. The transmitted energy is drawn down through the conductive plasma channels to at least one intervening electrode mounted to a support structure. Charges flow down through the channels to the electrode as they approach ground and the conductive electrode carries the energy away from the laser assembly to avoid damage to or destruction thereof. The at least one electrode will then pass these charges onto a capacitor bank or other storage means to store them. The at least one electrode is mounted to a support structure housing heat dissipation means well known in the nuclear fission art. The light emitting means is preferably insulated from and/or located remotely from the at least one electrode in order to protect the former from damage which could result if the high order energy being transmitted through the plasma channels was not intercepted by the electrode(s). Ideal locations for the subject apparatus are also described.

[0017] There has thus been outlined, rather broadly, the more important components and features of the invention in order that the detailed description thereof that follows may be better understood, and in order that the present contribution to the art may be better appreciated. There are, of course, additional features of the invention that will be described hereinafter and which will form the subject matter of the claims appended hereto. In this respect, before explaining at least one embodiment of the invention in detail, it is to be understood that the invention is not limited in its application to the details of construction and to the arrangements of the components set forth in the following description or illustrated in the drawings. The invention is capable of other embodiments and of being practiced and carried out in various ways. Also, it is to be understood that the phraseology and terminology employed herein are for the purpose of description and should not be regarded as limiting. As such, those skilled in the art will appreciate that the conception, upon which this disclosure is based, may readily be utilized as a basis for the designing of other structures, methods and systems for carrying out the several purposes of the present invention. It is important, therefore, that the claims be regarded as including such equivalent constructions insofar as they do not depart from the spirit and scope of the present invention.

[0018] Further, the purpose of the foregoing abstract is to enable the U.S. Patent and Trademark Office and the public generally, and especially the scientists, engineers and practitioners in the art who are not familiar with patent or legal terms or phraseology, to determine quickly from a cursory inspection the nature and essence of the technical disclosure of the application. The abstract is neither intended to define the invention of the application, which is measured by the claims, nor is it intended to be limiting as to the scope of the invention in any way.

[0019] For a better understanding of the invention, its advantages and the specific objects attained by its uses, reference should be had to the accompanying drawings and descriptive matter in which there is illustrated a preferred embodiment of the invention.

BRIEF DESCRIPTION OF THE DRAWINGS

[0020] The invention will be better understood and objects other than those set forth above will become apparent when consideration is given to the following detailed description thereof. Such description makes reference to the annexed drawings wherein:

[0021] The invention will be better understood and objects other than those set forth above will become apparent when consideration is given to the following detailed description thereof. Such description makes reference to the annexed drawings wherein:

[0022] FIG. **1** is a highly simplified schematical view of energy being transmitted from the ionosphere to ground via concentric laser-induced plasma channels produced by the subject apparatus in atmosphere (not-to-scale);

[0023] FIG. **2** is simple schematic illustration of the subject apparatus for inducing the flow of charged particles from the ionosphere to ground through concentric laser induced plasma channels (not-to-scale); and

[0024] FIG. **3** is a simplified schematical view of the earth with a magnetic field (force) line along which the present invention may be carried out (not-to-scale).

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

[0025] Reference is now made to FIG. **1** in which there is illustrated a highly simplified schematic view of energy E being transmitted from the ionosphere **100** through atmosphere **102** via concentric plasma channels **36**,**38** generated by the subject apparatus which is designated generally by reference numeral **10**. Apparatus **10** is situated on the earth's surface **104** at preferred locations herein described.

[0026] Referring to FIG. **2**, apparatus **10** is comprised of three primary components: 1) a wireless conductive channel producing means **12** or "atmospheric auger" connected to an energy source **14**, 2) charged particle receiving means **16** and 3) energy storage means **18**. Each primary component is described in detail below, together with secondary components of the subject apparatus.

[0027] Wireless conductive channel producing means **12** (hereinafter "plasma channel producing means") is comprised of first ionizing beam emitting means **20** used to create a first ionizing beam **22**, and second ionizing beam emitting means **24** used to create a second ionizing beam **26**. The term "ionizing beam emitting means" as used herein includes not only presently known lasers, but also other light sources which will excite ionization in a medium. Lasers utilize the natural oscillations of atoms or molecules between energy levels for generating beams **22**,**26** of highly amplified and coherent electromagnetic radiation of one or more discrete frequencies, which in turn generate first and second conductive paths **28**,**30**, respectively. The laser means used to establish conductive paths **28**,**30** should be selected with regard to energy, pulsewidth and wavelength so that it provides control of ionization concentration in each plasma channel. In a gas medium it is important that the ionizing beams **22**,**26** are controlled for optimum transmission of a charge.

[0028] Technologies that facilitate the creation of the subject con-channels include recent advancements in ultra-high intensity pulsed lasers and their transmission optics which together can generate a plasma field and have precise control over the field's geometry. Information regarding the manipulation and transmission of high powered lasers is generally classified due to the nature of their application. It is well known however, that successful high power laser systems are currently operation, and it follows that the condition and control optics are in place to handle such a system. According to an embodiment described herein, this technology is adapted to generate the con-channels. Ultra-high power pulsed or continuous lasers are now available in the Megawatt class, such as the Airborne Laser (ABL) built by Northrop Grumman. The lasers employed by the subject apparatus and methods should also by capable of varying the chirp of the input pulse to achieve control of the filamentation over horizontal kilometric distances. By way of example, one embodiment may include a Ti:sapphire CPA (Chirp Pulse Amplification) laser system operating at 10 Hz and delivering a maximum output power of 0.2 TW per pulse. The pulse duration approximates 130-135 fs (FWHM). The beam may be truncated by a circular aperture having a desired radius in order to have a more stable beam shape with a perfect or near-perfect circular symmetry.

[0029] Those skilled in the art will readily recognize that there are two main mechanisms responsible for the photoionization of air: avalanche ionization and multiphoton ionization. In avalanche ionization, or sometimes known as cascade ionization, the bound electrons in the valence shell of air molecules usually have an energy bandgap greater than the incident laser photon energy. However, a small number of free electrons exist. These free electrons may be generated through high altitude ionization of air molecules, radicals, break-up of aerosol molecules, thermal ionization or multiphoton ionization. These free electrons constitute the required seed electrons for avalanche ionization. Although these free electrons may exist in small number initially and have low kinetic energy, through a process called inverse bremsstrahlung, they can be accelerated to gain enough kinetic energy to impact ionize a molecule in collision, resulting in more free but slower electrons. The whole process repeats itself with more electrons gaining higher kinetic energy, exceeding the ionization potential of the bound electrons, to impact even more molecules, leading to an avalanche with the resultant formation of a plasma. In this inverse bremsstrahlung process, the free electrons absorb photons through the laser field when they collide with atoms or molecules. A free electron does not absorb laser energy directly without any collision. This is because the free electron simply quivers in the oscillating laser field, and when averaged over an optical cycle, it does not gain any net energy. The other dominant photoionization mechanism is the multi photon ionization process. Through this process, bound electrons may absorb several laser photons simultaneously to overcome their ionization potential. Multiphoton ionization depends largely on the laser operating frequency. Either method may be employed with the subject application.

[0030] In order to transform first and second conductive paths **28**,**30** into the desired cylindrical-shaped first and second plasma channels **36**,**38** it is necessary to cause their movement around a common central axis **40**. First and second beam moving means **32**,**34** are provided for this purpose and are comprised of either or a combination of mechanical or optical means. The manner in which at least two concentric plasma channels are generated using first and second ionizing beams **22**,**26** is not critical provided the properties (i.e., length, ionization intensity, uniformity, etc.) of each channel is controllable. Applicant's co-pending U.S. patent application entitled, Wireless Transmission Of Energy Through Concentric Laser-Induced Plasma Channels In Atmosphere, filed contemporaneously with the instant application and incorporated herein in its entirety, teaches at least one method of producing at least two concentric plasma channels. As previously stated, the term "channel" means a conduit, substantially ring-shaped in cross-section, having walls comprised of partially ionized gas ("plasma"), each wall being created by the movement of first and second conductive paths **28**,**30**, respectively. First plasma channel **36** and second plasma channel **38** share a common central longitudinal axis; they are concentric channels (or co-axial from a three-dimensional linear perspective). In alternate embodiments, the outermost channel and any channels between it and the innermost channel may be shaped like a funnel or frustum, narrower at point of origin and progressing outward as it extends into the atmosphere. U.S. Pat. No. 6,377,436 issued to Margolin on Apr. 23, 2002 and entitled, Microwave Transmission Using a Laser-Generated Plasma Beam Waveguide, which said reference is incorporated herein in its entirety to the extent it is not inconsistent with the explicit teachings of this specification, teaches various directed energy beam systems in the form of channels or "shells". Although the Margolin shells are used as a guide through which microwaves are transmitted rather than high order energy, the means by which the shells are created are instructive and find utility in the instant case. It should be appreciated that multiple concentric plasma channels may be created with at least two being the minimum required and at least three channels being preferred.

[0031] With continued reference to FIG. **2**, power to each ionizing beam emitting means is supplied by energy source **14**. The voltage required is related to and increases with the length of the path to be ionized. The energy in Joules required to excite the gas molecules in the path into ionization can be calculated in advance knowing the density of the molecules and the approximate diameter and length of the conductive path over which the energy from the ionosphere is to be transmitted. By way of example, energy source **14** may be comprised of a Marx generator which is capable of generating a high-voltage pulse. Voltages produced may exceed 2 million volts.

[0032] Charged particle collection means **16** comprises a charged particle attraction structure. Such structure includes at least one elongated electrode **42** generally somewhat similar to the lightning rods which are normally used to direct the electrical energy to ground when protecting buildings and the like. Electrode **42** is mounted to a support structure **44** generally, and to a conductive hemispherical dome **46** thereof specifically. A charge indicated by symbol + is applied to the at least one electrode **42** and/or dome **46** via charging means **48** which can impart a charge via conduction or induction (friction being impractical). Note that the + symbol is used as a substitute for the more conventional symbol "e" which of course can be either positive or negative. The hemispherical shape allows for the widest variance of charge wandering during energy transfer to the Earth's surface. This orb-like structure may include openings through its ionosphere-facing surface to allow the transmission of at least one ionizing beam therethrough with the actual light emitting means located remotely enough from the orb surface to mitigate against damage from expected energy loads.

[0033] The induction of ionospheric energy utilizing the subject apparatus **10** may be likened to the induction of a lighting strike, only of greater magnitude. A lightning strike discharges about 1-10 billion joules of energy and produces a current of some 30,000-50,000 amps, which heats the surrounding air to over 20,000 degrees Celsius. A single lightning bolt unleashes as much energy as blowing up a ton of TNT. Because of the enormous amount of heat attendant with the collection of ionospheric energy, even over a relatively short period of time, heat dissipation means are associated with the subject apparatus **10**. In one embodiment, heat dissipation means may be housed within support structure **44** as indicated by the "down arrow delta" symbol. Alternatively, heat dissipation means may be connected to support structure **44** but remote therefrom. Guidance for the design of a safe and efficient cooling system may be found in the nuclear science field of art for example, or in other power generation facilities. The main types (mechanisms) of heat transfer to be employed are 1) Wet cooling towers or simply cooling towers which operate on the principle of evaporation wherein the working fluid and the evaporated fluid (usually H_2O) are one and the same; 2) Dry coolers which operate by heat transfer through a surface that separates the working fluid from ambient air, such as in a heat exchanger, utilizing convective heat transfer (they do not use evaporation); and 3) Fluid coolers which are hybrids that pass the working fluid through a tube bundle, upon which clean water is sprayed and a fan-induced draft applied; the resulting heat transfer performance is much closer to that of a wet cooling tower, with the advantage provided by a dry cooler of protecting the working fluid from environmental exposure. In all applications, water may be tapped from a nearby water source **50** or other fluids used. Steam turbines (not shown) may be utilized to extract thermal energy from pressurized steam and convert it into rotary motion for the generation of electricity which may be utilized locally to power system components and/or fed to a local power grid **106**. Note that the release of steam in the ionospheric energy induction process will interfere with the photo-ionization of surrounding air and is therefore undesirable.

[0034] Once ionospheric particles are attracted to charged particle collection means **16** in the above described manner, the resulting electrical current is directed through the heat dissipation means via a first wire conductor **52** downwardly through support structure **44** to a surge arrestor assembly designated generally by reference numeral **54**. Such surge arrestor assembly is connected directly to ground **56** and has a switching assembly (not shown for purposes of clarity). The switch assembly is a structural adaptation of the surge arrestor assembly **54** serves automatically or manually to direct current flow either to energy storage means **18** via second wire conductor **58** when the conductive path is "open" or to ground **56** when the conduction path is closed. Energy storage means **18** may be comprised of, for example, a capacitor bank as illustrated or some other suitable means such as a collection coil of superconductive material as has been proposed in the art.

[0035] Various systems, methods and apparatus may be employed to convert the energy stored in energy storage means **18** to use. By way of example only, when energy stored within energy storage means **18** is required, a suitable switching apparatus (not shown for purposes of clarity) may be activated and the stored energy passed through a converter apparatus **60** structurally adapted to convert current coming from energy storage means **18** from D.C. to A.C. The A.C. current may then be passed through a transformer **62** for the purpose of regulating voltage before the current is directed into the power grid **106** for practical distribution and use. Energy may be transmitted from transformer **62** to power grid **106** via conventional power take-off means **64** and/or wirelessly **66** in a manner described in applicant's aforementioned co-pending application.

[0036] In operation, ionizing beam emitting means may be applied in continuous or, more likely, pulsed fashion, as determined by controller **68** used to activate energy source **14**. Alternatively, at least one ionizing beam emitting means may be operated in continuous fashion while at least one other ionizing beam emitting means may be operated in pulsed fashion. The intensity of both may additionally be modulated. In the event that the emitting means provides outputs which are continuous the control circuit will comprise merely on-off means, but where pulsed lasers and/or a pulsed energy source are used, the control circuit will comprise a trigger, suitable for firing each ionizing beam emitting, and also for controlling the rate at which each repeat their outputs. Pulsed systems have the advantage of providing quiescent intervals between their output pulses during which the ionized plasma in the portion of the beam which is located between the electrodes can die out to permit the system to start all over again and re-establish a straight-line highly conductive path of narrow and well defined proportions. The periodic extinguishing of each channel in a pulsed system is beneficial since it allows unstable ionization to die out so that it can be reestablished in a new channel which is both straight, and highly defined and concentrated. The subject apparatus provides a means of assuring that at least one plasma channel **36**,**38**, etc. is always open at any point in time thereby assuring that the energy to be transmitted always has a pre-defined conductive path to travel upon to the target collection means **16**. For instance, while plasma channel **32** is extinguished, controller **68** assures that plasma channel **36** is active. As previously stated, the periodic discharges from the at least two ionizing beam emitting means can be synchronized to produce, in the aggregate, a constant directional plasma channel between the ionosphere and ground. The overall transition of the Earth's atmosphere within the concentric laser induced plasma channels from insulator to conductor is in correlation to the Bose-Hubbard (boson Hubbard) model. In contrast to relatively low order energy transfer at colder temperatures demonstrated by fermion conductors, the subject invention provides high order energy transfer at ambient temperatures using Hubbard's principles as applied to bosons.

[0037] FIG. **2** illustrates the manner in which energy is transmitted from its point of origin in the ionosphere **104** to collection means **16**. First and second plasma channels **36**,**38** comprise a plasma which is highly conductive and which is propagating along directional arrow **108**. Prior to transmission of ionospheric charged particles, designated by circumscribed minus signs, through plasma channels **36**,**38**, the channels remain fairly well defined for a usable interval of time. However, when the energy to be transmitted is introduced into and travels along a given plasma channel, the charge will eventually begin to self constrict due to magnetic forces stemming from the current flowing through the plasma causing the charge to close upon itself and leaving the energy being transmitted with no clear path to follow, potentially striking unintended targets.

[0038] The employment of at least two, and preferably at least three, concentric plasma channels in accordance with the subject invention mitigates such occurrences by providing adjacent conductive paths which ionospheric energy can "jump to" when losing its point-to-point direction. After the charge transitions to its new conductive path, the last-travelled path is regenerated by its corresponding ionization beam emitting means. The subject apparatus and methods, therefore, provide that at least one conductive path is always open and in close proximity to a neighboring current-carrying plasma channel.

[0039] In the example illustrated in FIG. **2**, a potential exists between free charged particles in the ionosphere, on the one hand, and charged electrode **42** and dome **46** on the other. First and second plasma channels **36**,**38** provide a bridge between them for the transmission of the former to the latter. Charged particles from the ionosphere are drawn into the walls of whichever plasma channel is open at the time (in the instant illustration, plasma channel **36**, and begin to travel downwardly there along a first distance or time interval d_1 until the current is pinched and can no longer travel along its current channel. At that time the errant current will seek out a new path of least resistance on the way to collection means **16**. The closest path of least resistance will be the then open neighboring channel **38** onto which the current will "jump" and then travel a second distance or time interval d_2. As energy traverses its new channel the previously traversed plasma channel **36** will be reformed serving as the next adjacent "jump site" for current to find when it again experiences pinch. The charge will jump from channel to channel, traveling a distance or time interval along each, in alternating or "stair-step" down fashion until reaching energy collection means **16**. Once energy collection means **16** reaches capacity, power to the light emitting means may be relinquished and the magnetic spin of the transferred charged particles will close the field. It is possible, of course, that in certain circumstances a particular charge will remain open while traversing a single channel to the target. What is important is that there is always a predefined alternate directional conductive path in close proximity for the energy to travel upon.

[0040] As previously mentioned, the ionosphere is most distinct above 80 km (50 miles) where the ions and free electrons move rapidly under the influence of electrical forces-the ionospheric wind-and where the ionosphere is highly conductive. During fair weather there is an electric potential difference of 250,000 to 500,000 volts between the ionosphere and the Earth's surface. Accordingly, construction of the subject apparatus in locations which facilitate tapping this region of the atmosphere are desirable, particularly at high elevations where the air to be ionized contains a lower percentage of contaminants which adversely affect propagation of conductive plasma channels.

[0041] Additionally, reference now being made to FIG. **3**, in the upper regions of the ionosphere, beginning several hundred kilometers above Earth's surface and extending tens of thousands of kilometers into space, is the magnetosphere, a region where the behavior of charged particles is strongly affected by the magnetic fields of Earth and the Sun. The solar wind is a stream of charged particles ejected from the upper atmosphere of the sun. It consists mostly of electrons and protons with energies of about 1 keV. As the solar wind approaches Earth's well-developed magnetic field, the particles are deflected by the Lorentz force. This region, known as the magnetosphere, causes the particles to travel around the planet rather than bombarding the atmosphere or surface. However some of the charged particles leak through this magnetic barrier and become trapped in the Van Allen radiation belt. A smaller number of particles from the solar wind manage to travel, as though on an electromagnetic energy transmission line, to the Earth's upper atmosphere and ionosphere in the auroral zones. More specifically, the charged particles travel through funnel-like openings (cusps **110**) at the North and South Poles, releasing tremendous energy when they hit the upper atmosphere. The Northern and Southern Lights (auroras) are the visible evidence of this energy transfer from the Sun to the Earth. These regions, approximately 13 latitude 14 n longitude, and where magnetic field lines intersect the Earth, are believed to be ideal for employment of the subject apparatus **10**. It may be advantageous to locate the subject system and apparatus at a dwindling or soon to be decommissioned mine, because of pre-existing environmental permits and useful tunnels.

[0042] Although the present invention has been described with reference to the particular embodiments herein set forth, it is understood that the present disclosure has been made only by way of example and that numerous changes in details of construction may be resorted to without departing from the spirit and scope of the invention. Thus, the scope of the invention should not be limited by the foregoing specifications, but rather only by the scope of the claims appended hereto.

1. An apparatus for inducing the flow of charged particles from the charge-rich outer atmosphere to ground, comprising:

a. means for generating a first conductive channel through the atmosphere and in communication with the charge-rich outer atmosphere, said first conductive channel being substantially ring-shaped in cross-section and comprised of a wall of partially ionized atmosphere; said first conductive channel having a diameter;

b. means for generating a second conductive channel through the atmosphere and in communication with the charge-rich outer atmosphere, said second conductive channel being substantially ring-shaped in cross-section and comprised of a wall of partially ionized atmosphere; said second conductive channel having a diameter greater than said diameter of said first conductive channel; said first conductive channel and said second conductive channel being concentric; and

c. charged particle collection means associated with said means for generating said first and said second conductive channels.

2. The apparatus for inducing the flow of charged particles from the charge-rich outer atmosphere to ground of claim **1**, wherein said charged particle collection means is comprised of a at least one electrode attached to a support structure.

3. The apparatus for inducing the flow of charged particles from the charge-rich outer atmosphere to ground of claim **2**, wherein said support structure comprises a conductive hemispherical dome.

4. The apparatus for inducing the flow of charged particles from the charge-rich outer atmosphere to ground of claim **2**, wherein one or more of said at least one electrode and said support structure are charged.

5. The apparatus for inducing the flow of charged particles from the charge-rich outer atmosphere to ground of claim **3**, wherein one or more of said at least one electrode and said hemispherical dome are charged.

6. The apparatus for inducing the flow of charged particles from the charge-rich outer atmosphere to ground of claim **1**, wherein said second conductive channel is funnel shaped being more narrow at its point of origin.

7. The apparatus for inducing the flow of charged particles from the charge-rich outer atmosphere to ground of claim **2**, wherein said second conductive channel is funnel shaped being more narrow at its point of origin.

8. The apparatus for inducing the flow of charged particles from the charge-rich outer atmosphere to ground of claim **3**, wherein said second conductive channel is funnel shaped being more narrow at its point of origin.

9. The apparatus for inducing the flow of charged particles from the charge-rich outer atmosphere to ground of claim **4**, wherein said second conductive channel is funnel shaped being more narrow at its point of origin.

10. The apparatus for inducing the flow of charged particles from the charge-rich outer atmosphere to ground of claim **5**, wherein said second conductive channel is funnel shaped being more narrow at its point of origin.

11. The apparatus for inducing the flow of charged particles from the charge-rich outer atmosphere to ground of claim **1**, further including means for momentarily or periodically extinguishing said first conductive channel, said second conductive channel, or asynchronously both.

12. The apparatus for inducing the flow of charged particles from the charge-rich outer atmosphere to ground of claim **2**, further including means for momentarily or periodically extinguishing said first conductive channel, said second conductive channel, or asynchronously both.

13. The apparatus for inducing the flow of charged particles from the charge-rich outer atmosphere to ground of claim **3**, further including means for momentarily or periodically extinguishing said first conductive channel, said second conductive channel, or asynchronously both.

14. The apparatus for inducing the flow of charged particles from the charge-rich outer atmosphere to ground of claim **4**, further including means for momentarily or periodically extinguishing said first conductive channel, said second conductive channel, or asynchronously both.

15. The apparatus for inducing the flow of charged particles from the charge-rich outer atmosphere to ground of claim **5**, further including means for momentarily or periodically extinguishing said first conductive channel, said second conductive channel, or asynchronously both.

16. The apparatus for inducing the flow of charged particles from the charge-rich outer atmosphere to ground of claim **6**, further including means for momentarily or periodically extinguishing said first conductive channel, said second conductive channel, or asynchronously both.

17. The apparatus for inducing the flow of charged particles from the charge-rich outer atmosphere to ground of claim **7**, further including means for momentarily or periodically extinguishing said first conductive channel, said second conductive channel, or asynchronously both.

18. The apparatus for inducing the flow of charged particles from the charge-rich outer atmosphere to ground of claim **8**, further including means for momentarily or periodically extinguishing said first conductive channel, said second conductive channel, or asynchronously both.

19. The apparatus for inducing the flow of charged particles from the charge-rich outer atmosphere to ground of claim **9**, further including means for momentarily or periodically extinguishing said first conductive channel, said second conductive channel, or asynchronously both.

20. The apparatus for inducing the flow of charged particles from the charge-rich outer atmosphere to ground of claim **10**, further including means for momentarily or periodically extinguishing said first conductive channel, said second conductive channel, or asynchronously both.

[57] ABSTRACT

A method and apparatus for altering at least one selected region which normally exists above the earth's surface. The region is excited by electron cyclotron resonance heating to thereby increase its charged particle density. In one embodiment, circularly polarized electromagnetic radiation is transmitted upward in a direction substantially parallel to and along a field line which extends through the region of plasma to be altered. The radiation is transmitted at a frequency which excites electron cyclotron resonance to heat and accelerate the charged particles. This increase in energy can cause ionization of neutral particles which are then absorbed as part of the region thereby increasing the charged particle density of the region.

FIG. 5

METHOD AND APPARATUS FOR ALTERING A REGION IN THE EARTH'S ATMOSPHERE, IONOSPHERE, AND/OR MAGNETOSPHERE

DESCRIPTION

1. Technical Field

This invention relates to a method and apparatus for altering at least one selected region normally existing above the earth's surface and more particularly relates to a method and apparatus for altering said at least one region by initially transmitting electromagnetic radiation from the earth's surface essentially parallel to and along naturally-occurring, divergent magnetic field lines which extend from the earth's surface through the region or regions to be altered.

2. Background Art

In the late 1950's, it was discovered that naturally-occuring belts exist at high altitudes above the earth's surface, and it is now established that these belts result from charged electrons and ions becoming trapped along the magnetic lines of force (field lines) of the earth's essentially dipole magnetic field. The trapped electrons and ions are confined along the field lines between two magnetic mirrors which exist at spaced apart points along those field lines. The trapped electrons and ions move in helical paths around their particular field lines and "bounce" back and forth between the magnetic mirrors. These trapped electrons and ions can oscillate along the field lines for long periods of time.

In the past several years, substantial effort has been made to understand and explain the phenomena involved in belts of trapped electrons and ions, and to explore possible ways to control and use these phenomena for beneficial purposes. For example, in the late 1950's and early 1960's both the United States and U.S.S.R. detonated a series of nuclear devices of various yields to generate large numbers of charged particles at various altitudes, e.g., 200 kilometers (km) or greater. This was done in order to establish and study artifical belts of trapped electrons and ions. These experiments established that at least some of the extraneous electrons and ions from the detonated devices did become trapped along field lines in the earth's magnetosphere to form artificial belts which were stable for prolonged periods of time. For a discussion of these experiments see "The Radiation Belt and Magnetosphere", W. N. Hess, Blaisdell Publishing Co., 1968, pps. 155 et sec.

Other proposals which have been advanced for altering existing belts of trapped electrons and ions and/or establishing similar artificial belts include injecting charged particles from a satellite carrying a payload of radioactive beta-decay material or alpha emitters; and injecting charged particles from a satellite-borne electron accelerator. Still another approach is described in U.S. Pat. No. 4,042,196 wherein a low energy ionized gas, e.g., hydrogen, is released from a synchronous orbiting satellite near the apex of a radiation belt which is naturally-occurring in the earth's magnetosphere to produce a substantial increase in energetic particle precipitation and, under certain conditions, produce a limit in the number of particles that can be stably trapped. This precipitation effect arises from an enhancement of the whistler-mode and ion-cyclotron mode interactions that result from the ionized gas or "cold plasma" injection.

It has also been proposed to release large clouds of barium in the magnetosphere so that photoionization will increase the cold plasma density, thereby producing electron precipitation through enhanced whistler-mode interactions.

However, in all of the above-mentioned approaches, the mechanisms involved in triggering the change in the trapped particle phenomena must be actually positioned within the affected zone, e.g., the magnetosphere, before they can be actuated to effect the desired change.

The earth's ionosphere is not considered to be a "trapped" belt since there are few trapped particles therein. The term "trapped" herein refers to situations where the force of gravity on the trapped particles is balanced by magnetic forces rather than hydrostatic or collisional forces. The charged electrons and ions in the ionosphere also follow helical paths around magnetic field lines within the ionosphere but are not trapped between mirrors, as in the case of the trapped belts in the magnetosphere, since the gravitational force on the particles is balanced by collisional or hydrostatic forces.

In recent years, a number of experiments have actually been carried out to modify the ionosphere in some controlled manner to investigate the possibility of a beneficial result. For detailed discussions of these operations see the following papers: (1) Ionospheric Modification Theory; G. Meltz and F. W. Perkins; (2) The Platteville High Power Facility; Carrol et al.; (3) Arecibo Heating Experiments; W. E. Gordon and H. C. Carlson, Jr.; and (4) Ionospheric Heating by Powerful Radio Waves; Meltz et al., all published in Radio Science, Vol. 9, No. 11, November, 1974, at pages 885–888; 889–894; 1041–1047; and 1049–1063, respectively, all of which are incorporated herein by reference. In such experiments, certain regions of the ionosphere are heated to change the electron density and temperature within these regions. This is accomplished by transmitting from earth-based antennae high frequency electromagnetic radiation at a substantial angle to, not parallel to, the ionosphere's magnetic field to heat the ionospheric particles primarily by ohmic heating. The electron temperature of the ionosphere has been raised by hundreds of degrees in these experiments, and electrons with several electron volts of energy have been produced in numbers sufficient to enhance airglow. Electron concentrations have been reduced by a few percent, due to expansion of the plasma as a result of increased temperature.

In the Elmo Bumpy Torus (EBT), a controlled fusion device at the Oak Ridge National Laboratory, all heating is provided by microwaves at the electron cyclotron resonance interaction. A ring of hot electrons is formed at the earth's surface in the magnetic mirror by a combination of electron cyclotron resonance and stochastic heating. In the EBT, the ring electrons are produced with an average "temperature" of 250 kilo electron volts or kev (2.5×10^9K) and a plasma beta between 0.1 and 0.4; see, "A Theoretical Study of Electron—Cyclotron Absorption in Elmo Bumpy Torus", Batchelor and Goldfinger, Nuclear Fusion, Vol. 20, No. 4 (1980) pps. 403–418.

Electron cyclotron resonance heating has been used in experiments on the earth's surface to produce and accelerate plasmas in a diverging magnetic field. Kosmahl et al. showed that power was transferred from the electromagnetic waves and that a fully ionized plasma

was accelerated with a divergence angle of roughly 13 degrees. Optimum neutral gas density was 1.7×10^{14} per cubic centimeter; see, "Plasma Acceleration with Microwaves Near Cyclotron Resonance", Kosmahl et al., Journal of Applied Physics, Vol. 38, No. 12, Nov., 1967, pps. 4576–4582.

DISCLOSURE OF THE INVENTION

The present invention provides a method and apparatus for altering at least one selected region which normally exists above the earth's surface. The region is excited by electron cyclotron resonance heating of electrons which are already present and/or artifically created in the region to thereby increase the charged particle energy and ultimately the density of the region.

In one embodiment this is done by transmitting circularly polarized electromagnetic radiation from the earth's surface at or near the location where a naturally-occurring dipole magnetic field (force) line intersects the earth's surface. Right hand circular polarization is used in the northern hemisphere and left hand circular polarization is used in the southern hemisphere. The radiation is deliberately transmitted at the outset in a direction substantially parallel to and along a field line which extends upwardly through the region to be altered. The radiation is transmitted at a frequency which is based on the gyrofrequency of the charged particles and which, when applied to the at least one region, excites electron cyclotron resonance within the region or regions to heat and accelerate the charged particles in their respective helical paths around and along the field line. Sufficient energy is employed to cause ionization of neutral particles (molecules of oxygen, nitrogen and the like, particulates, etc.) which then become a part of the region thereby increasing the charged particle density of the region. This effect can further be enhanced by providing artificial particles, e.g., electrons, ions, etc., directly into the region to be affected from a rocket, satellite, or the like to supplement the particles in the naturally-occurring plasma. These artificial particles are also ionized by the transmitted electromagnetic radiation thereby increasing charged particle density of the resulting plasma in the region.

In another embodiment of the invention, electron cyclotron resonance heating is carried out in the selected region or regions at sufficient power levels to allow a plasma present in the region to generate a mirror force which forces the charged electrons of the altered plasma upward along the force line to an altitude which is higher than the original altitude. In this case the relevant mirror points are at the base of the altered region or regions. The charged electrons drag ions with them as well as other particles that may be present. Sufficient power, e.g., 10^{15} joules, can be applied so that the altered plasma can be trapped on the field line between mirror points and will oscillate in space for prolonged periods of time. By this embodiment, a plume of altered plasma can be established at selected locations for communication modification or other purposes.

In another embodiment, this invention is used to alter at least one selected region of plasma in the ionosphere to establish a defined layer of plasma having an increased charged particle density. Once this layer is established, and while maintaining the transmission of the main beam of circularly polarized electromagnetic radiation, the main beam is modulated and/or at least one second different, modulated electromagnetic radiation beam is transmitted from at least one separate source at a different frequency which will be absorbed in the plasma layer. The amplitude of the frequency of the main beam and/or the second beam or beams is modulated in resonance with at least one known oscillation mode in the selected region or regions to excite the known oscillation mode to propagate a known frequency wave or waves throughout the ionosphere.

BRIEF DESCRIPTION OF THE DRAWINGS

The actual construction, operation, and apparent advantages of this invention will be better understood by referring to the drawings in which like numerals identify like parts and in which:

FIG. **1** is a simplified schematical view of the earth (not to scale) with a magnetic field (force) line along which the present invention is carried out;

FIG. **2** is one embodiment within the present invention in which a selected region of plasma is raised to a higher altitude;

FIG. **3** is a simplified, idealized representation of a physical phenomenon involved in the present invention; and

FIG. **4** is a schematic view of another embodiment within the present invention.

FIG. **5** is a schematic view of an apparatus embodiment within this invention.

BEST MODES FOR CARRYING OUT THE INVENTION

The earth's magnetic field is somewhat analogous to a dipole bar magnet. As such, the earth's magnetic field contains numerous divergent field or force lines, each line intersecting the earth's surface at points on opposite sides of the Equator. The field lines which intersect the earth's surface near the poles have apexes which lie at the furthest points in the earth's magnetosphere while those closest to the Equator have apexes which reach only the lower portion of the magnetosphere.

At various altitudes above the earth's surface, e.g., in both the ionosphere and the magnetosphere, plasma is naturally present along these field lines. This plasma consists of equal numbers of positively and negatively charged particles (i.e., electrons and ions) which are guided by the field line. It is well established that a charged particle in a magnetic field gyrates about field lines, the center of gyration at any instance being called the "guiding center" of the particle. As the gyrating particle moves along a field line in a uniform field, it will follow a helical path about its guiding center, hence linear motion, and will remain on the field line. Electrons and ions both follow helical paths around a field line but rotate in opposite directions. The frequencies at which the electrons and ions rotate about the field line are called gyromagnetic frequencies or cyclotron frequencies because they are identical with the expression for the angular frequencies of gyration of particles in a cyclotron. The cyclotron frequency of ions in a given magnetic field is less than that of electrons, in inverse proportion to their masses.

If the particles which form the plasma along the earth's field lines continued to move with a constant pitch angle, often designated "alpha", they would soon impact on the earth's surface. Pitch angle alpha is defined as the angle between the direction of the earth's magnetic field and the velocity (V) of the particle. However, in converging force fields, the pitch angle does change in such a way as to allow the particle to

turn around and avoid impact. Consider a particle moving along a field line down toward the earth. It moves into a region of increasing magnetic field strength and therefore sine alpha increases. But sine alpha can only increase to 1.0, at which point, the particle turns around and starts moving up along the field line, and alpha decreases. The point at which the particle turns around is called the mirror point, and there alpha equals ninety degrees. This process is repeated at the other end of the field line where the same magnetic field strength value B, namely Bm, exists. The particle again turns around and this is called the "conjugate point" of the original mirror point. The particle is therefore trapped and bounces between the two magnetic mirrors. The particle can continue oscillating in space in this manner for long periods of time. The actual place where a particle will mirror can be calculated from the following:

$$\sin^2 \text{alpha}_o = B_o/B_m \quad (1)$$

wherein:

alpha_o = equatorial pitch angle of particle

B_o = equatorial field strength on a particular field line

B_m = field strength at the mirror point

Recent discoveries have established that there are substantial regions of naturally trapped particles in space which are commonly called "trapped radiation belts". These belts occur at altitudes greater than about 500 km and accordingly lie in the magnetosphere and mostly above the ionosphere.

The ionosphere, while it may overlap some of the trapped-particle belts, is a region in which hydrostatic forces govern its particle distribution in the gravitational field. Particle motion within the ionosphere is governed by both hydrodynamic and electrodynamic forces. While there are few trapped particles in the ionosphere, nevertheless, plasma is present along field lines in the ionosphere. The charged particles which form this plasma move between collisions with other particles along similar helical paths around the field lines and although a particular particle may diffuse downward into the earth's lower atmosphere or lose energy and diverge from its original field line due to collisions with other particles, these charged particles are normally replaced by other available charged particles or by particles that are ionized by collision with said particle. The electron density (N_e) of the plasma will vary with the actual conditions and locations involved. Also, neutral particles, ions, and electrons are present in proximity to the field lines.

The production of enhanced ionization will also alter the distribution of atomic and molecular constituents of the atmosphere, most notably through increased atomic nitrogen concentration. The upper atmosphere is normally rich in atomic oxygen (the dominant atmospheric constituent above 200 km altitude), but atomic nitrogen is normally relatively rare. This can be expected to manifest itself in increased airglow, among other effects.

As known in plasma physics, the characteristics of a plasma can be altered by adding energy to the charged particles or by ionizing or exciting additional particles to increase the density of the plasma. One way to do this is by heating the plasma which can be accomplished in different ways, e.g., ohmic, magnetic compression, shock waves, magnetic pumping, electron cyclotron resonance, and the like.

Since electron cyclotron resonance heating is involved in the present invention, a brief discussion of same is in order. Increasing the energy of electrons in a plasma by invoking electron cyclotron resonance heating, is based on a principle similar to that utilized to accelerate charged particles in a cyclotron. If a plasma is confined by a static axial magnetic field of strength B, the charged particles will gyrate about the lines of force with a frequency given, in hertz, as $f_g = 1.54 \times 10^3 B/A$, where: B = magnetic field strength in gauss, and A = mass number of the ion.

Suppose a time-varying field of this frequency is superimposed on the static field B confining the plasma, by passage of a radiofrequency current through a coil which is concentric with that producing the axial field, then in each half-cycle of their rotation about the field lines, the charged particles acquire energy from the oscillating electric field associated with the radio frequency. For example, if B is 10,000 gauss, the frequency of the field which is in resonance with protons in a plasma is 15.4 megahertz.

As applied to electrons, electron cyclotron resonance heating requires an oscillating field having a definite frequency determined by the strength of the confining field. The radio-frequency radiation produces time-varying fields (electric and magnetic), and the electric field accelerates the charged particle. The energized electrons share their energy with ions and neutrals by undergoing collisions with these particles, thereby effectively raising the temperature of the electrons, ions, and neutrals. The apportionment of energy among these species is determined by collision frequencies. For a more detailed understanding of the physics involved, see "Controlled Thermonuclear Reactions", Glasstone and Lovberg, D. Van Nostrand Company, Inc., Princeton, N.J., 1960 and "The Radiation Belt and Magnetosphere", Hess, Blaisdell Publishing Company, 1968, both of which are incorporated herein by reference.

Referring now to the drawings, the present invention provides a method and apparatus for altering at least one region of plasma which lies along a field line, particularly when it passes through the ionosphere and/or magnetosphere. FIG. **1** is a simplified illustration of the earth **10** and one of its dipole magnetic force or field lines **11**. As will be understood, line **11** may be any one of the numerous naturally existing field lines and the actual geographical locations **13** and **14** of line **11** will be chosen based on a particular operation to be carried out. The actual locations at which field lines intersect the earth's surface is documented and is readily ascertainable by those skilled in the art.

Line **11** passes through region R which lies at an altitude above the earth's surface. A wide range of altitudes are useful given the power that can be employed by the practice of this invention. The electron cyclotron resonance heating effect can be made to act on electrons anywhere above the surface of the earth. These electrons may be already present in the atmosphere, ionosphere, and/or magnetosphere of the earth, or can be artificially generated by a variety of means such as x-ray beams, charged particle beams, lasers, the plasma sheath surrounding an object such as a missile or meteor, and the like. Further, artificial particles, e.g., electrons, ions, etc., can be injected directly into region R from an earth-launched rocket or orbiting satellite carrying, for example, a payload of radioactive beta-decay material; alpha emitters; an electron accelerator; and/or ionized gases such as hydrogen; see U.S. Pat. No. 4,042,196. The altitude can be greater than about 50 km if desired,

e.g., can be from about 50 km to about 800 km, and, accordingly may lie in either the ionosphere or the magnetosphere or both. As explained above, plasma will be present along line **11** within region R and is represented by the helical line **12**. Plasma **12** is comprised of charged particles (i.e., electrons and ions) which rotate about opposing helical paths along line **11**.

Antenna **15** is positioned as close as is practical to the location **14** where line **11** intersects the earth's surface. Antenna **15** may be of any known construction for high directionality, for example, a phased array, beam spread angle (θ) type. See "The MST Radar at Poker Flat, Alaska", Radio Science, Vol. 15, No. 2, Mar.-Apr. 1980, pps. 213–223, which is incorporated herein by reference. Antenna **15** is coupled to transmitter **16** which generates a beam of high frequency electromagnetic radiation at a wide range of discrete frequencies, e.g., from about 20 to about 1800 kilohertz (kHz).

Transmitter **16** is powered by power generator means **17** which is preferably comprised of one or more large, commercial electrical generators. Some embodiments of the present invention require large amounts of power, e.g., up to 10^9 to 10^{11} watts, in continuous wave or pulsed power. Generation of the needed power is within the state of the art. Although the electrical generators necessary for the practice of the invention can be powered in any known manner, for example, by nuclear reactors, hydroelectric facilities, hydrocarbon fuels, and the like, this invention, because of its very large power requirement in certain applications, is particularly adapted for use with certain types of fuel sources which naturally occur at strategic geographical locations around the earth. For example, large reserves of hydrocarbons (oil and natural gas) exist in Alaska and Canada. In northern Alaska, particularly the North Slope region, large reserves are currently readily available. Alaska and northern Canada also are ideally located geographically as to magnetic latitudes. Alaska provides easy access to magnetic field lines that are especially suited to the practice of this invention, since many field lines which extend to desirable altitudes for this invention intersect the earth in Alaska. Thus, in Alaska, there is a unique combination of large, accessible fuel sources at desirable field line intersections. Further, a particularly desirable fuel source for the generation of very large amounts of electricity is present in Alaska in abundance, this source being natural gas. The presence of very large amounts of clean-burning natural gas in Alaskan latitudes, particularly on the North Slope, and the availability of magnetohydrodynamic (MHD), gas turbine, fuel cell, electrogasdynamic (EGD) electric generators which operate very efficiently with natural gas provide an ideal power source for the unprecedented power requirements of certain of the applications of this invention. For a more detailed discussion of the various means for generating electricity from hydrocarbon fuels, see "Electrical Aspects of Combustion", Lawton and Weinberg, Clarendon Press, 1969. For example, it is possible to generate the electricity directly at the high frequency needed to drive the antenna system. To do this, typically the velocity of flow of the combustion gases (v), past magnetic field perturbation of dimension d (in the case of MHD), follow the rule:

$$v=df$$

where f is the frequency at which electricity is generated. Thus, if $v=1.78\times10^6$ cm/sec and $d=1$ cm then electricity would be generated at a frequency of 1.78 mHz.

Put another way, in Alaska, the right type of fuel (natural gas) is naturally present in large amounts and at just the right magnetic latitudes for the most efficient practice of this invention, a truly unique combination of circumstances. Desirable magnetic latitudes for the practice of this invention interest the earth's surface both northerly and southerly of the equator, particularly desirable latitudes being those, both northerly and southerly, which correspond in magnitude with the magnetic latitudes that encompass Alaska.

Referring now to FIG. **2** a first ambodiment is illustrated where a selected region R_1 of plasma **12** is altered by electron cyclotron resonance heating to accelerate the electrons of plasma **12**, which are following helical paths along field line **11**.

To accomplish this result, electromagnetic radiation is transmitted at the outset, essentially parallel to line **11** via antenna **15** as right hand circularly polarized radiation wave **20**. Wave **20** has a frequency which will excite electron cyclotron resonance with plasma **12** at its initial or original altitude. This frequency will vary depending on the electron cyclotron resonance of region R_1 which, in turn, can be determined from available data based on the altitudes of region R_1, the particular field line **11** being used, the strength of the earth's magnetic field, etc. Frequencies of from about 20 to about 7200 kHz, preferably from about 20 to about 1800 kHz can be employed. Also, for any given application, there will be a threshhold (minimum power level) which is needed to produce the desired result. The minimum power level is a function of the level of plasma production and movement required, taking into consideration any loss processes that may be dominant in a particular plasma or propagation path.

As electron cyclotron resonance is established in plasma **12**, energy is transferred from the electromagnetic radiation **20** into plasma **12** to heat and accelerate the electrons therein and, subsequently, ions and neutral particles. As this process continues, neutral particles which are present within R_1 are ionized and absorbed into plasma **12** and this increases the electron and ion densities of plasma **12**. As the electron energy is raised to values of about 1 kilo electron volt (kev), the generated mirror force (explained below) will direct the excited plasma **12** upward along line **11** to form a plume R_2 at an altitude higher than that of R_1.

Plasma acceleration results from the force on an electron produced by a nonuniform static magnetic field ($\overline{B}$). The force, called the mirror force, is given by

$$F=-\mu\nabla B \quad (2)$$

where μ is the electron magnetic moment and $\nabla\overline{B}$ is the gradient of the magnetic field, μ being further defined as:

$$W_{\perp}/B=mV_{\perp}^2/2B$$

where $W_{\perp}$ is the kinetic energy in the direction perpendicular to that of the magnetic field lines and B is the magnetic field strength at the line of force on which the guiding center of the particle is located. The force as represented by equation (2) is the force which is responsible for a particle obeying equation (1).

Since the magnetic field is divergent in region R_1, it can be shown that the plasma will move upwardly from the heating region as shown in FIG. **1** and further it can be shown that

$$\tfrac{1}{2}M_eV_{e\perp}^2(x) \simeq \tfrac{1}{2}M_eV_{e\perp}^2(Y) + \tfrac{1}{2}M_iV_{i\parallel}^2(Y) \quad (3)$$

where the left hand side is the initial electron transverse kinetic energy; the first term on the right is the transverse electron kinetic energy at some point (Y) in the expanded field region, while the final term is the ion kinetic energy parallel to B at point (Y). This last term is what constitutes the desired ion flow. It is produced by an electrostatic field set up by electrons which are accelerated according to Equation (2) in the divergent field region and pulls ions along with them. Equation (3) ignores electron kinetic energy parallel to B because $V_{e\parallel} \approx V_{i\parallel}$, so the bulk of parallel kinetic energy resides in the ions because of their greater masses. For example, if an electromagnetic energy flux of from about 1 to about 10 watts per square centimeter is applied to region R, whose altitude is 115 km, a plasma having a density (N_e) of 10^{12} per cubic centimeter will be generated and moved upward to region R_2 which has an altitude of about 1000 km. The movement of electrons in the plasma is due to the mirror force while the ions are moved by ambipolar diffusion (which results from the electrostatic field). This effectively "lifts" a layer of plasma **12** from the ionosphere and/or magnetosphere to a higher elevation R_2. The total energy required to create a plasma with a base area of 3 square kilometers and a height of 1000 km is about 3×10^{13} joules.

FIG. **3** is an idealized representation of movement of plasma **12** upon excitation by electron cyclotron resonance within the earth's divergent force field. Electrons (e) are accelerated to velocities required to generate the necessary mirror force to cause their upward movement. At the same time neutral particles (n) which are present along line **11** in region $R_1$are ionized and become part of plasma **12**. As electrons (e) move upward along line **11**, they drag ions (i) and neutrals (n) with them but at an angle θ of about 13 degrees to field line **11**. Also, any particulates that may be present in region R_1, will be swept upwardly with the plasma. As the charged particles of plasma **12** move upward, other particles such as neutrals within or below R_1, move in to replace the upwardly moving particles. These neutrals, under some conditions, can drag with them charged particles.

For example, as a plasma moves upward, other particles at the same altitude as the plasma move horizontally into the region to replace the rising plasma and to form new plasma. The kinetic energy developed by said other particles as they move horizontally is, for example, on the same order of magnitude as the total zonal kinetic energy of stratospheric winds known to exist.

Referring again to FIG. **2**, plasma **12** in region R_1 is moved upward along field line **11**. The plasma **12** will then form a plume (cross-hatched area in FIG. **2**) which will be relatively stable for prolonged periods of time. The exact period of time will vary widely and be determined by gravitational forces and a combination of radiative and diffusive loss terms. In the previous detailed example, the calculations were based on forming a plume by producing 0^+energies of 2 ev/particle. About 10 ev per particle would be required to expand plasma **12** to apex point C (FIG. **1**). There at least some of the particles of plasma **12** will be trapped and will oscillate between mirror points along field line **11**. This oscillation will then allow additional heating of the trapped plasma **12** by stochastic heating which is associated with trapped and oscillating particles. See "A New Mechanism for Accelerating Electrons in the Outer Ionosphere" by R. A. Helliwell and T. F. Bell, Journal of Geophysical Research, Vol. 65, No. 6, June, 1960. This is preferably carried out at an altitude of at least 500 km.

The plasma of the typical example might be employed to modify or disrupt microwave transmissions of satellites. If less than total black-out of transmission is desired (e.g., scrambling by phase shifting digital signals), the density of the plasma (N_e) need only be at least about 10^6 per cubic centimeter for a plasma orginating at an altitude of from about 250 to about 400 km and accordingly less energy (i.e., electromagnetic radiation), e.g., 10^8 joules need be provided. Likewise, if the density $N_e$is on the order of 10^8, a properly positioned plume will provide a reflecting surface for VHF waves and can be used to enhance, interfere with, or otherwise modify communication transmissions. It can be seen from the foregoing that by appropriate application of various aspects of this invention at strategic locations and with adequate power sources, a means and method is provided to cause interference with or even total disruption of communications over a very large portion of the earth. This invention could be employed to disrupt not only land based communications, both civilian and military, but also airborne communications and sea communications (both surface and subsurface). This would have significant military implications, particularly as a barrier to or confusing factor for hostile missiles or airplanes. The belt or belts of enhanced ionization produced by the method and apparatus of this invention, particularly if set up over Northern Alaska and Canada, could be employed as an early warning device, as well as a communications disruption medium. Further, the simple ability to produce such a situation in a practical time period can by itself be a deterring force to hostile action. The ideal combination of suitable field lines intersecting the earth's surface at the point where substantial fuel sources are available for generation of very large quantitities of electromagnetic power, such as the North Slope of Alaska, provides the wherewithal to accomplish the foregoing in a practical time period, e.g., strategic requirements could necessitate achieving the desired altered regions in time periods of two minutes or less and this is achievable with this invention, especially when the combination of natural gas and magnetohydrodynamic, gas turbine, fuel cell and/or EGD electric generators are employed at the point where the useful field lines intersect the earth's surface. One feature of this invention which satisfies a basic requirement of a weapon system, i.e., continuous checking of operability, is that small amounts of power can be generated for operability checking purposes. Further, in the exploitation of this invention, since the main electromagnetic beam which generates the enhanced ionized belt of this invention can be modulated itself and/or one or more additional electromagnetic radiation waves can be impinged on the ionized region formed by this invention as will be described in greater detail herein after with respect to FIG. **4**, a substantial amount of randomly modulated signals of very large power magnitude can be generated in a highly nonlinear mode. This can cause confusion of or interference with or even complete disruption of guidance systems employed by

even the most sophisticated of airplanes and missiles. The ability to employ and transmit over very wide areas of the earth a plurality of electromagnetic waves of varying frequencies and to change same at will in a random manner, provides a unique ability to interfere with all modes of communications, land, sea, and/or air, at the same time. Because of the unique juxtaposition of usable fuel source at the point where desirable field lines intersect the earth's surface, such wide ranging and complete communication interference can be achieved in a resonably short period of time. Because of the mirroring phenomenon discussed hereinabove, it can also be prolonged for substantial time periods so that it would not be a mere transient effect that could simply be waited out by an opposing force. Thus, this invention provides the ability to put unprecedented amounts of power in the earth's atmosphere at strategic locations and to maintain the power injection level, particularly if random pulsing is employed, in a manner far more precise and better controlled than heretofore accomplished by the prior art, particularly by the detonation of nuclear devices of various yeilds at various altitudes. Where the prior art approaches yielded merely transitory effects, the unique combination of fuel and desirable field lines at the point where the fuel occurs allows the establishment of, compared to prior art approaches, precisely controlled and long-lasting effects which cannot, practically speaking, simply be waited out. Further, by knowing the frequencies of the various electromagnetic beams employed in the practice of this invention, it is possible not only to interfere with third party communications but to take advantage of one or more such beams to carry out a communications network even though the rest of the world's communications are disrupted. Put another way, what is used to disrupt another's communications can be employed by one knowledgeable of this invention as a communications network at the same time. In addition, once one's own communication network is established, the far-reaching extent of the effects of this invention could be employed to pick up communication signals of other for intelligence purposes. Thus, it can be seen that the disrupting effects achievable by this invention can be employed to benefit by the party who is practicing this invention since knowledge of the various electromagnetic waves being employed and how they will vary in frequency and magnitude can be used to an advantage for positive communication and eavesdropping purposes at the same time. However, this invention is not limited to locations where the fuel source naturally exists or where desirable field lines naturally intersect the earth's surface. For example, fuel, particularly hydrocarbon fuel, can be transported by pipeline and the like to the location where the invention is to be practiced.

FIG. 4 illustrates another embodiment wherein a selected region of plasma R_3which lies within the earth's ionosphere is altered to increase the density thereof whereby a relatively stable layer **30** of relatively dense plasma is maintained within region R_3. Electromagnetic radiation is transmitted at the outset essentially parallel to field line **11** via antenna **15** as a right hand circularly polarized wave and at a frequency (e.g., 1.78 megahertz when the magnetic field at the desired altitude is 0.66 gauss) capable of exciting electron cyclotron resonance in plasma **12** at the particular altitude of plasma **12**. This causes heating of the particles (electrons, ions, neutrals, and particulates) and ionization of the uncharged particles adjacent line **11**, all of which are absorbed into plasma **12** to increase the density thereof. The power transmitted, e.g., 2×10^6 watts for up to 2 minutes heating time, is less than that required to generate the mirror force F required to move plasma **12** upward as in the previous embodiment.

While continuing to transmit electromagnetic radiation **20** from antenna **15**, a second electromagnetic radiation beam **31**, which is at a defined frequency different from the radiation from antenna **15**, is transmitted from one or more second sources via antenna **32** into layer **30** and is absorbed into a portion of layer **30** (cross-hatched area in FIG. **4**). The electromagnetic radiation wave from antenna **32** is amplitude modulated to match a known mode of oscillation f_3 in layer **30**. This creates a resonance in layer **30** which excites a new plasma wave **33** which also has a frequency of f_3 and which then propogates through the ionosphere. Wave **33** can be used to improve or disrupt communications or both depending on what is desired in a particular application. Of course, more than one new wave **33** can be generated and the various new waves can be modulated at will and in a highly nonlinear fashion.

FIG. **5** shows apparatus useful in this invention, particularly when those applications of this invention are employed which require extremely large amounts of power. In FIG. **5** there is shown the earth's surface **40** with a well **41** extending downwardly thereinto until it penetrates hydrocarbon producing reservoir **42**. Hydrocarbon reservoir **42** produces natural gas alone or in combination with crude oil. Hydrocarbons are produced from reservoir **42** through well **41** and wellhead **43** to a treating system **44** by way of pipe **45**. In treater **44**, desirable liquids such as crude oil and gas condensates are separated and recovered by way of pipe **46** while undesirable gases and liquids such as water, H_2S, and the like are separated by way of pipe **47**. Desirable gases such as carbon dioxide are separated by way of pipe **48**, and the remaining natural gas stream is removed from treater **44** by way of pipe **49** for storage in conventional tankage means (not shown) for future use and/or use in an electrical generator such as a magnetohydrodynamic, gas turbine, fuel cell or EGD generator **50**. Any desired number and combination of different types of electric generators can be employed in the practice of this invention. The natural gas is burned in generator **50** to produce substantial quantities of electricity which is then stored and/or passed by way of wire **51** to a transmitter **52** which generates the electromagnetic radiation to be used in the method of this invention. The electromagnetic radiation is then passed by way of wire **53** to antenna **54** which is located at or near the end of field line **11**. Antenna **54** sends circularly polarized radiation wave **20** upwards along field line **11** to carry out the various methods of this invention as described hereinabove.

Of course, the fuel source need not be used in its naturally-occurring state but could first be converted to another second energy source form such as hydrogen, hydrazine and the like, and electricity then generated from said second energy source form.

It can be seen from the foregoing that when desirable field line **11** intersects earth's surface **40** at or near a large naturally-occurring hydrocarbon source **42**, exceedingly large amounts of power can be very efficiently produced and transmitted in the direction of field lines. This is particularly so when the fuel source is natural gas and magnetohydrodynamic generators are employed. Further, this can all be accomplished in a

relatively small physical area when there is the unique coincidence of fuel source **42** and desirable field line **11**. Of course, only one set of equipment is shown in FIG. **5** for sake of simplicity. For a large hydrocarbon reservoir **42**, a plurality of wells **41** can be employed to feed one or more storage means and/or treaters and as large a number of generators **55** as needed to power one or more transmitters **52** and one or more antennas **54**. Since all of the apparatus **44** through **54** can be employed and used essentially at the sight where naturally-occurring fuel source **42** is located, all the necessary electromagnetic radiation **20** is generated essentially at the same location as fuel source **42**. This provides for a maximum amount of usable electromagnetic radiation **20** since there are no significant storage or transportation losses to be incurred. In other words, the apparatus is brought to the sight of the fuel source where desirable field line **11** intersects the earth's surface **40** on or near the geographical location of fuel source **42**, fuel source **42** being at a desirable magnetic latitude for the practice of this invention, for example, Alaska.

The generation of electricity by motion of a conducting fluid through a magnetic field, i.e., magnetohydrodynamics (MHD), provides a method of electric power generation without moving mechanical parts and when the conducting fluid is a plasma formed by combustion of a fuel such as natural gas, an idealized combination of apparatus is realized since the very clean-burning natural gas forms the conducting plasma in an efficient manner and the thus formed plasma, when passed through a magnetic field, generates electricity in a very efficient manner. Thus, the use of fuel source **42** to generate a plasma by combustion thereof for the generation of electricity essentially at the site of occurrence of the fuel source is unique and ideal when high power levels are required and desirable field lines **11** intersect the earth's surface **40** at or near the site of fuel source **42**. A particular advantage for MHD generators is that they can be made to generate large amounts of power with a small volume, light weight device. For example, a 1000 megawatt MHD generator can be construed using superconducting magnets to weigh roughly 42,000 pounds and can be readily air lifted.

This invention has a phenomenal variety of possible ramifications and potential future developments. As alluded to earlier, missile or aircraft destruction, deflection, or confusion could result, particularly when relativistic particles are employed. Also, large regions of the atmosphere could be lifted to an unexpectedly high altitude so that missiles encounter unexpected and unplanned drag forces with resultant destruction or deflection of same. Weather modification is possible by, for example, altering upper atmosphere wind patterns or altering solar absorption patterns by constructing one or more plumes of atmospheric particles which will act as a lens or focusing device. Also as alluded to earlier, molecular modifications of the atmosphere can take place so that positive environmental effects can be achieved. Besides actually changing the molecular composition of an atmospheric region, a particular molecule or molecules can be chosen for increased presence. For example, ozone, nitrogen, etc. concentrations in the atmosphere could be artificially increased. Similarly, environmental enhancement could be achieved by causing the breakup of various chemical entities such as carbon dioxide, carbon monoxide, nitrous oxides, and the like. Transportation of entities can also be realized when advantage is taken of the drag effects caused by regions of the atmosphere moving up along diverging field lines. Small micron sized particles can be then transported, and, under certain circumstances and with the availability of sufficient energy, larger particles or objects could be similarly affected. Particles with desired characteristics such as tackiness, reflectivity, absorptivity, etc., can be transported for specific purposes or effects. For example, a plume of tacky particles could be established to increase the drag on a missile or satellite passing therethrough. Even plumes of plasma having substantially less charged particle density than described above will produce drag effects on missiles which will affect a lightweight (dummy) missile in a manner substantially different than a heavy (live) missile and this affect can be used to distinguish between the two types of missiles. A moving plume could also serve as a means for supplying a space station or for focusing vast amount of sunlight on selected portions of the earth. Surveys of global scope could also be realized because the earth's natural magnetic field could be significantly altered in a controlled manner by plasma beta effects resulting in, for example, improved magnetotelluric surveys. Electromagnetic pulse defenses are also possible. The earth's magnetic field could be decreased or disrupted at appropriate altitudes to modify or eliminate the magnetic field in high Compton electron generation (e.g., from high altitude nuclear bursts) regions. High intensity, well controlled electrical fields can be provided in selected locations for various purposes. For example, the plasma sheath surrounding a missile or satellite could be used as a trigger for activating such a high intensity field to destroy the missile or satellite. Further, irregularities can be created in the ionosphere which will interfere with the normal operation of various types of radar, e.g., synthetic aperture radar. The present invention can also be used to create artificial belts of trapped particles which in turn can be studied to determine the stability of such parties. Still further, plumes in accordance with the present invention can be formed to simulate and/or perform the same functions as performed by the detonation of a "heave" type nuclear device without actually having to detonate such a device. Thus it can be seen that the ramifications are numerous, far-reaching, and exceedingly varied in usefulness.

I claim:

1. A method for altering at least one region normally existing above the earth's surface with electromagnetic radiation using naturally-occurring and diverging magnetic field lines of the earth comprising transmitting first electromagnetic radiation at a frequency between 20 and 7200 kHz from the earth's surface, said transmitting being conducted essentially at the outset of transmission substantially parallel to and along at least one of said field lines, adjusting the frequency of said first radiation to a value which will excite electron cyclotron resonance at an initial elevation at least 50 km above the earth's surface, whereby in the region in which said electron cyclotron resonance takes place heating, further ionization, and movement of both charged and neutral particles is effected, said cyclotron resonance excitation of said region is continued until the electron concentration of said region reaches a value of at least 10^6 per cubic centimeter and has an ion energy of at least 2 ev.

2. The method of claim **1** including the step of providing artificial particles in said at least one region which are excited by said electron cyclotron resonance.

3. The method of claim **2** wherein said artificial particles are provided by injecting same into said at least one region from an orbiting satellite.

4. The method of claim **1** wherein said threshold excitation of electron cyclotron resonance is about 1 watt per cubic centimeter and is sufficient to cause movement of a plasma region along said diverging magnetic field lines to an altitude higher than the altitude at which said excitation was initiated.

5. The method of claim **4** wherein said rising plasma region pulls with it a substantial portion of neutral particles of the atmosphere which exist in or near said plasma region.

6. The method of claim **1** wherein there is provided at least one separate source of second electromagnetic radiation, said second radiation having at least one frequency different from said first radiation, impinging said at least one second radiation on said region while said region is undergoing electron cyclotron resonance excitation caused by said first radiation.

7. The method of claim **6** wherein said second radiation has a frequency which is absorbed by said region.

8. The method of claim **6** wherein said region is plasma in the ionosphere and said second radiation excites plasma waves within said ionosphere.

9. The method of claim **8** wherein said electron concentration reaches a value of at least 10^{12} per cubic centimeter.

10. The method of claim **8** wherein said excitation of electron cyclotron resonance is initially carried out within the ionosphere and is continued for a time sufficient to allow said region to rise above said ionosphere.

11. The method of claim **1** wherein said excitation of electron cyclotron resonance is carried out above about 500 kilometers and for a time of from 0.1 to 1200 seconds such that multiple heating of said plasma region is achieved by means of stochastic heating in the magnetosphere.

12. The method of claim **1** wherein said first electromagnetic radiation is right hand circularly polarized in the northern hemisphere and left hand circularly polarized in the southern hemisphere.

13. The method of claim **1** wherein said electromagnetic radiation is generated at the site of a naturally-occurring hydrocarbon fuel source, said fuel source being located in at least one of northerly or southerly magnetic latitudes.

14. The method of claim **13** wherein said fuel source is natural gas and electricity for generating said electromagnetic radiation is obtained by burning said natural gas in at least one of magnetohydrodynamic, gas turbine, fuel cell, and EGD electric generators located at the site where said natural gas naturally occurs in the earth.

15. The method of claim **14** wherein said site of natural gas is within the magnetic latitudes that encompass Alaska.

[57] **ABSTRACT**

A method and apparatus for altering at least one selected region which normally exists above the earth's surface. The region is excited by electron cyclotron resonance heating to thereby increase its charged particle density. In one embodiment, circularly polarized electromagnetic radiation is transmitted upward in a direction substantially parallel to and along a field line which extends through the region of plasma to be altered. The radiation is transmitted at a frequency which excites electron cyclotron resonance to heat and accelerate the charged particles. This increase in energy can cause ionization of neutral particles which are then absorbed as part of the region thereby increasing the charged particle density of the region.

METHOD AND APPARATUS FOR ALTERING A REGION IN THE EARTH'S ATMOSPHERE, IONOSPHERE, AND/OR MAGNETOSPHERE

DESCRIPTION

1. Technical Field

This invention relates to a method and apparatus for altering at least one selected region normally existing above the earth's surface and more particularly relates to a method and apparatus for altering said at least one region by initially transmitting electromagnetic radiation from the earth's surface essentially parallel to and along naturally-occurring, divergent magnetic field lines which extend from the earth's surface through the region or regions to be altered.

2. Background Art

In the late 1950's, it was discovered that naturally-occuring belts exist at high altitudes above the earth's surface, and it is now established that these belts result from charged electrons and ions becoming trapped along the magnetic lines of force (field lines) of the earth's essentially dipole magnetic field. The trapped electrons and ions are confined along the field lines between two magnetic mirrors which exist at spaced apart points along those field lines. The trapped electrons and ions move in helical paths around their particular field lines and "bounce" back and forth between the magnetic mirrors. These trapped electrons and ions can oscillate along the field lines for long periods of time.

In the past several years, substantial effort has been made to understand and explain the phenomena involved in belts of trapped electrons and ions, and to explore possible ways to control and use these phenomena for beneficial purposes. For example, in the late 1950's and early 1960's both the United States and U.S.S.R. detonated a series of nuclear devices of various yields to generate large numbers of charged particles at various altitudes, e.g., 200 kilometers (km) or greater. This was done in order to establish and study artifical belts of trapped electrons and ions. These experiments established that at least some of the extraneous electrons and ions from the detonated devices did become trapped along field lines in the earth's magnetosphere to form artificial belts which were stable for prolonged periods of time. For a discussion of these experiments see "The Radiation Belt and Magnetosphere", W. N. Hess, Blaisdell Publishing Co., 1968, pps. 155 et sec.

Other proposals which have been advanced for altering existing belts of trapped electrons and ions and/or establishing similar artificial belts include injecting charged particles from a satellite carrying a payload of radioactive beta-decay material or alpha emitters; and injecting charged particles from a satellite-borne electron accelerator. Still another approach is described in U.S. Pat. No. 4,042,196 wherein a low energy ionized gas, e.g., hydrogen, is released from a synchronous orbiting satellite near the apex of a radiation belt which is naturally-occurring in the earth's magnetosphere to produce a substantial increase in energetic particle precipitation and, under certain conditions, produce a limit in the number of particles that can be stably trapped. This precipitation effect arises from an enhancement of the whistler-mode and ion-cyclotron mode interactions that result from the ionized gas or "cold plasma" injection.

It has also been proposed to release large clouds of barium in the magnetosphere so that photoionization will increase the cold plasma density, thereby producing electron precipitation through enhanced whistler-mode interactions.

However, in all of the above-mentioned approaches, the mechanisms involved in triggering the change in the trapped particle phenomena must be actually positioned within the affected zone, e.g., the magnetosphere, before they can be actuated to effect the desired change.

The earth's ionosphere is not considered to be a "trapped" belt since there are few trapped particles therein. The term "trapped" herein refers to situations where the force of gravity on the trapped particles is balanced by magnetic forces rather than hydrostatic or collisional forces. The charged electrons and ions in the ionosphere also follow helical paths around magnetic field lines within the ionosphere but are not trapped between mirrors, as in the case of the trapped belts in the magnetosphere, since the gravitational force on the particles is balanced by collisional or hydrostatic forces.

In recent years, a number of experiments have actually been carried out to modify the ionosphere in some controlled manner to investigate the possibility of a beneficial result. For detailed discussions of these operations see the following papers: (1) Ionospheric Modification Theory; G. Meltz and F. W. Perkins; (2) The Platteville High Power Facility; Carrol et al.; (3) Arecibo Heating Experiments; W. E. Gordon and H. C. Carlson, Jr.; and (4) Ionospheric Heating by Powerful Radio Waves; Meltz et al., all published in Radio Science, Vol. 9, No. 11, November, 1974, at pages 885–888; 889–894; 1041–1047; and 1049–1063, respectively, all of which are incorporated herein by reference. In such experiments, certain regions of the ionosphere are heated to change the electron density and temperature within these regions. This is accomplished by transmitting from earth-based antennae high frequency electromagnetic radiation at a substantial angle to, not parallel to, the ionosphere's magnetic field to heat the ionospheric particles primarily by ohmic heating. The electron temperature of the ionosphere has been raised by hundreds of degrees in these experiments, and electrons with several electron volts of energy have been produced in numbers sufficient to enhance airglow. Electron concentrations have been reduced by a few percent, due to expansion of the plasma as a result of increased temperature.

In the Elmo Bumpy Torus (EBT), a controlled fusion device at the Oak Ridge National Laboratory, all heating is provided by microwaves at the electron cyclotron resonance interaction. A ring of hot electrons is formed at the earth's surface in the magnetic mirror by a combination of electron cyclotron resonance and stochastic heating. In the EBT, the ring electrons are produced with an average "temperature" of 250 kilo electron volts or kev (2.5×10^9K) and a plasma beta between 0.1 and 0.4; see, "A Theoretical Study of Electron—Cyclotron Absorption in Elmo Bumpy Torus", Batchelor and Goldfinger, Nuclear Fusion, Vol. 20, No. 4 (1980) pps. 403–418.

Electron cyclotron resonance heating has been used in experiments on the earth's surface to produce and accelerate plasmas in a diverging magnetic field. Kosmahl et al. showed that power was transferred from the electromagnetic waves and that a fully ionized plasma

was accelerated with a divergence angle of roughly 13 degrees. Optimum neutral gas density was 1.7×10^{14} per cubic centimeter; see, "Plasma Acceleration with Microwaves Near Cyclotron Resonance", Kosmahl et al., Journal of Applied Physics, Vol. 38, No. 12, Nov., 1967, pps. 4576–4582.

DISCLOSURE OF THE INVENTION

The present invention provides a method and apparatus for altering at least one selected region which normally exists above the earth's surface. The region is excited by electron cyclotron resonance heating of electrons which are already present and/or artifically created in the region to thereby increase the charged particle energy and ultimately the density of the region.

In one embodiment this is done by transmitting circularly polarized electromagnetic radiation from the earth's surface at or near the location where a naturally-occurring dipole magnetic field (force) line intersects the earth's surface. Right hand circular polarization is used in the northern hemisphere and left hand circular polarization is used in the southern hemisphere. The radiation is deliberately transmitted at the outset in a direction substantially parallel to and along a field line which extends upwardly through the region to be altered. The radiation is transmitted at a frequency which is based on the gyrofrequency of the charged particles and which, when applied to the at least one region, excites electron cyclotron resonance within the region or regions to heat and accelerate the charged particles in their respective helical paths around and along the field line. Sufficient energy is employed to cause ionization of neutral particles (molecules of oxygen, nitrogen and the like, particulates, etc.) which then become a part of the region thereby increasing the charged particle density of the region. This effect can further be enhanced by providing artificial particles, e.g., electrons, ions, etc., directly into the region to be affected from a rocket, satellite, or the like to supplement the particles in the naturally-occurring plasma. These artificial particles are also ionized by the transmitted electromagnetic radiation thereby increasing charged particle density of the resulting plasma in the region.

In another embodiment of the invention, electron cyclotron resonance heating is carried out in the selected region or regions at sufficient power levels to allow a plasma present in the region to generate a mirror force which forces the charged electrons of the altered plasma upward along the force line to an altitude which is higher than the original altitude. In this case the relevant mirror points are at the base of the altered region or regions. The charged electrons drag ions with them as well as other particles that may be present. Sufficient power, e.g., 10^{15} joules, can be applied so that the altered plasma can be trapped on the field line between mirror points and will oscillate in space for prolonged periods of time. By this embodiment, a plume of altered plasma can be established at selected locations for communication modification or other purposes.

In another embodiment, this invention is used to alter at least one selected region of plasma in the ionosphere to establish a defined layer of plasma having an increased charged particle density. Once this layer is established, and while maintaining the transmission of the main beam of circularly polarized electromagnetic radiation, the main beam is modulated and/or at least one second different, modulated electromagnetic radiation beam is transmitted from at least one separate source at a different frequency which will be absorbed in the plasma layer. The amplitude of the frequency of the main beam and/or the second beam or beams is modulated in resonance with at least one known oscillation mode in the selected region or regions to excite the known oscillation mode to propagate a known frequency wave or waves throughout the ionosphere.

BRIEF DESCRIPTION OF THE DRAWINGS

The actual construction, operation, and apparent advantages of this invention will be better understood by referring to the drawings in which like numerals identify like parts and in which:

FIG. **1** is a simplified schematical view of the earth (not to scale) with a magnetic field (force) line along which the present invention is carried out;

FIG. **2** is one embodiment within the present invention in which a selected region of plasma is raised to a higher altitude;

FIG. **3** is a simplified, idealized representation of a physical phenomenon involved in the present invention; and

FIG. **4** is a schematic view of another embodiment within the present invention.

FIG. **5** is a schematic view of an apparatus embodiment within this invention.

BEST MODES FOR CARRYING OUT THE INVENTION

The earth's magnetic field is somewhat analogous to a dipole bar magnet. As such, the earth's magnetic field contains numerous divergent field or force lines, each line intersecting the earth's surface at points on opposite sides of the Equator. The field lines which intersect the earth's surface near the poles have apexes which lie at the furthest points in the earth's magnetosphere while those closest to the Equator have apexes which reach only the lower portion of the magnetosphere.

At various altitudes above the earth's surface, e.g., in both the ionosphere and the magnetosphere, plasma is naturally present along these field lines. This plasma consists of equal numbers of positively and negatively charged particles (i.e., electrons and ions) which are guided by the field line. It is well established that a charged particle in a magnetic field gyrates about field lines, the center of gyration at any instance being called the "guiding center" of the particle. As the gyrating particle moves along a field line in a uniform field, it will follow a helical path about its guiding center, hence linear motion, and will remain on the field line. Electrons and ions both follow helical paths around a field line but rotate in opposite directions. The frequencies at which the electrons and ions rotate about the field line are called gyromagnetic frequencies or cyclotron frequencies because they are identical with the expression for the angular frequencies of gyration of particles in a cyclotron. The cyclotron frequency of ions in a given magnetic field is less than that of electrons, in inverse proportion to their masses.

If the particles which form the plasma along the earth's field lines continued to move with a constant pitch angle, often designated "alpha", they would soon impact on the earth's surface. Pitch angle alpha is defined as the angle between the direction of the earth's magnetic field and the velocity (V) of the particle. However, in converging force fields, the pitch angle does change in such a way as to allow the particle to

turn around and avoid impact. Consider a particle moving along a field line down toward the earth. It moves into a region of increasing magnetic field strength and therefore sine alpha increases. But sine alpha can only increase to 1.0, at which point, the particle turns around and starts moving up along the field line, and alpha decreases. The point at which the particle turns around is called the mirror point, and there alpha equals ninety degrees. This process is repeated at the other end of the field line where the same magnetic field strength value B, namely Bm, exists. The particle again turns around and this is called the "conjugate point" of the original mirror point. The particle is therefore trapped and bounces between the two magnetic mirrors. The particle can continue oscillating in space in this manner for long periods of time. The actual place where a particle will mirror can be calculated from the following:

$$\sin^2 \text{alpha}_o = B_o/B_m \tag{1}$$

wherein:

alpha$_o$=equatorial pitch angle of particle

B_o=equatorial field strength on a particular field line

B_m=field strength at the mirror point

Recent discoveries have established that there are substantial regions of naturally trapped particles in space which are commonly called "trapped radiation belts". These belts occur at altitudes greater than about 500 km and accordingly lie in the magnetosphere and mostly above the ionosphere.

The ionosphere, while it may overlap some of the trapped-particle belts, is a region in which hydrostatic forces govern its particle distribution in the gravitational field. Particle motion within the ionosphere is governed by both hydrodynamic and electrodynamic forces. While there are few trapped particles in the ionosphere, nevertheless, plasma is present along field lines in the ionosphere. The charged particles which form this plasma move between collisions with other particles along similar helical paths around the field lines and although a particular particle may diffuse downward into the earth's lower atmosphere or lose energy and diverge from its original field line due to collisions with other particles, these charged particles are normally replaced by other available charged particles or by particles that are ionized by collision with said particle. The electron density (N_e) of the plasma will vary with the actual conditions and locations involved. Also, neutral particles, ions, and electrons are present in proximity to the field lines.

The production of enhanced ionization will also alter the distribution of atomic and molecular constituents of the atmosphere, most notably through increased atomic nitrogen concentration. The upper atmosphere is normally rich in atomic oxygen (the dominant atmospheric constituent above 200 km altitude), but atomic nitrogen is normally relatively rare. This can be expected to manifest itself in increased airglow, among other effects.

As known in plasma physics, the characteristics of a plasma can be altered by adding energy to the charged particles or by ionizing or exciting additional particles to increase the density of the plasma. One way to do this is by heating the plasma which can be accomplished in different ways, e.g., ohmic, magnetic compression, shock waves, magnetic pumping, electron cyclotron resonance, and the like.

Since electron cyclotron resonance heating is involved in the present invention, a brief discussion of same is in order. Increasing the energy of electrons in a plasma by invoking electron cyclotron resonance heating, is based on a principle similar to that utilized to accelerate charged particles in a cyclotron. If a plasma is confined by a static axial magnetic field of strength B, the charged particles will gyrate about the lines of force with a frequency given, in hertz, as $f_g = 1.54 \times 10^3 B/A$, where: B=magnetic field strength in gauss, and A=mass number of the ion.

Suppose a time-varying field of this frequency is superimposed on the static field B confining the plasma, by passage of a radiofrequency current through a coil which is concentric with that producing the axial field, then in each half-cycle of their rotation about the field lines, the charged particles acquire energy from the oscillating electric field associated with the radio frequency. For example, if B is 10,000 gauss, the frequency of the field which is in resonance with protons in a plasma is 15.4 megahertz.

As applied to electrons, electron cyclotron resonance heating requires an oscillating field having a definite frequency determined by the strength of the confining field. The radio-frequency radiation produces time-varying fields (electric and magnetic), and the electric field accelerates the charged particle. The energized electrons share their energy with ions and neutrals by undergoing collisions with these particles, thereby effectively raising the temperature of the electrons, ions, and neutrals. The apportionment of energy among these species is determined by collision frequencies. For a more detailed understanding of the physics involved, see "Controlled Thermonuclear Reactions", Glasstone and Lovberg, D. Van Nostrand Company, Inc., Princeton, N.J., 1960 and "The Radiation Belt and Magnetosphere", Hess, Blaisdell Publishing Company, 1968, both of which are incorporated herein by reference.

Referring now to the drawings, the present invention provides a method and apparatus for altering at least one region of plasma which lies along a field line, particularly when it passes through the ionosphere and/or magnetosphere. FIG. **1** is a simplified illustration of the earth **10** and one of its dipole magnetic force or field lines **11**. As will be understood, line **11** may be any one of the numerous naturally existing field lines and the actual geographical locations **13** and **14** of line **11** will be chosen based on a particular operation to be carried out. The actual locations at which field lines intersect the earth's surface is documented and is readily ascertainable by those skilled in the art.

Line **11** passes through region R which lies at an altitude above the earth's surface. A wide range of altitudes are useful given the power that can be employed by the practice of this invention. The electron cyclotron resonance heating effect can be made to act on electrons anywhere above the surface of the earth. These electrons may be already present in the atmosphere, ionosphere, and/or magnetosphere of the earth, or can be artificially generated by a variety of means such as x-ray beams, charged particle beams, lasers, the plasma sheath surrounding an object such as a missile or meteor, and the like. Further, artificial particles, e.g., electrons, ions, etc., can be injected directly into region R from an earth-launched rocket or orbiting satellite carrying, for example, a payload of radioactive beta-decay material; alpha emitters; an electron accelerator; and/or ionized gases such as hydrogen; see U.S. Pat. No. 4,042,196. The altitude can be greater than about 50 km if desired,

e.g., can be from about 50 km to about 800 km, and, accordingly may lie in either the ionosphere or the magnetosphere or both. As explained above, plasma will be present along line **11** within region R and is represented by the helical line **12**. Plasma **12** is comprised of charged particles (i.e., electrons and ions) which rotate about opposing helical paths along line **11**.

Antenna **15** is positioned as close as is practical to the location **14** where line **11** intersects the earth's surface. Antenna **15** may be of any known construction for high directionality, for example, a phased array, beam spread angle (θ) type. See "The MST Radar at Poker Flat, Alaska", Radio Science, Vol. 15, No. 2, Mar.-Apr. 1980, pps. 213–223, which is incorporated herein by reference. Antenna **15** is coupled to transmitter **16** which generates a beam of high frequency electromagnetic radiation at a wide range of discrete frequencies, e.g., from about 20 to about 1800 kilohertz (kHz).

Transmitter **16** is powered by power generator means **17** which is preferably comprised of one or more large, commercial electrical generators. Some embodiments of the present invention require large amounts of power, e.g., up to 10^9 to 10^{11} watts, in continuous wave or pulsed power. Generation of the needed power is within the state of the art. Although the electrical generators necessary for the practice of the invention can be powered in any known manner, for example, by nuclear reactors, hydroelectric facilities, hydrocarbon fuels, and the like, this invention, because of its very large power requirement in certain applications, is particularly adapted for use with certain types of fuel sources which naturally occur at strategic geographical locations around the earth. For example, large reserves of hydrocarbons (oil and natural gas) exist in Alaska and Canada. In northern Alaska, particularly the North Slope region, large reserves are currently readily available. Alaska and northern Canada also are ideally located geographically as to magnetic latitudes. Alaska provides easy access to magnetic field lines that are especially suited to the practice of this invention, since many field lines which extend to desirable altitudes for this invention intersect the earth in Alaska. Thus, in Alaska, there is a unique combination of large, accessible fuel sources at desirable field line intersections. Further, a particularly desirable fuel source for the generation of very large amounts of electricity is present in Alaska in abundance, this source being natural gas. The presence of very large amounts of clean-burning natural gas in Alaskan latitudes, particularly on the North Slope, and the availability of magnetohydrodynamic (MHD), gas turbine, fuel cell, electrogasdynamic (EGD) electric generators which operate very efficiently with natural gas provide an ideal power source for the unprecedented power requirements of certain of the applications of this invention. For a more detailed discussion of the various means for generating electricity from hydrocarbon fuels, see "Electrical Aspects of Combustion", Lawton and Weinberg, Clarendon Press, 1969. For example, it is possible to generate the electricity directly at the high frequency needed to drive the antenna system. To do this, typically the velocity of flow of the combustion gases (v), past magnetic field perturbation of dimension d (in the case of MHD), follow the rule:

$$v=df$$

where f is the frequency at which electricity is generated. Thus, if $v=1.78\times10^6$ cm/sec and d=1 cm then electricity would be generated at a frequency of 1.78 mHz.

Put another way, in Alaska, the right type of fuel (natural gas) is naturally present in large amounts and at just the right magnetic latitudes for the most efficient practice of this invention, a truly unique combination of circumstances. Desirable magnetic latitudes for the practice of this invention interest the earth's surface both northerly and southerly of the equator, particularly desirable latitudes being those, both northerly and southerly, which correspond in magnitude with the magnetic latitudes that encompass Alaska.

Referring now to FIG. 2 a first ambodiment is illustrated where a selected region R_1 of plasma **12** is altered by electron cyclotron resonance heating to accelerate the electrons of plasma **12**, which are following helical paths along field line **11**.

To accomplish this result, electromagnetic radiation is transmitted at the outset, essentially parallel to line **11** via antenna **15** as right hand circularly polarized radiation wave **20**. Wave **20** has a frequency which will excite electron cyclotron resonance with plasma **12** at its initial or original altitude. This frequency will vary depending on the electron cyclotron resonance of region R_1 which, in turn, can be determined from available data based on the altitudes of region R_1, the particular field line **11** being used, the strength of the earth's magnetic field, etc. Frequencies of from about 20 to about 7200 kHz, preferably from about 20 to about 1800 kHz can be employed. Also, for any given application, there will be a threshhold (minimum power level) which is needed to produce the desired result. The minimum power level is a function of the level of plasma production and movement required, taking into consideration any loss processes that may be dominant in a particular plasma or propagation path.

As electron cyclotron resonance is established in plasma **12**, energy is transferred from the electromagnetic radiation **20** into plasma **12** to heat and accelerate the electrons therein and, subsequently, ions and neutral particles. As this process continues, neutral particles which are present within R_1 are ionized and absorbed into plasma **12** and this increases the electron and ion densities of plasma **12**. As the electron energy is raised to values of about 1 kilo electron volt (kev), the generated mirror force (explained below) will direct the excited plasma **12** upward along line **11** to form a plume R_2 at an altitude higher than that of R_1.

Plasma acceleration results from the force on an electron produced by a nonuniform static magnetic field ($\overline{B}$). The force, called the mirror force, is given by

$$F=-\mu\nabla B \qquad (2)$$

where μ is the electron magnetic moment and $\nabla\overline{B}$ is the gradient of the magnetic field, μ being further defined as:

$$W_\perp/B=mV_\perp^2/2B$$

where $W_\perp$ is the kinetic energy in the direction perpendicular to that of the magnetic field lines and B is the magnetic field strength at the line of force on which the guiding center of the particle is located. The force as represented by equation (2) is the force which is responsible for a particle obeying equation (1).

Since the magnetic field is divergent in region R_1, it can be shown that the plasma will move upwardly from the heating region as shown in FIG. **1** and further it can be shown that

$$\tfrac{1}{2}M_eV_{e\perp}^2(x) \approx \tfrac{1}{2}M_eV_{e\perp}^2(Y) + \tfrac{1}{2}M_iV_{i\parallel}^2(Y) \tag{3}$$

where the left hand side is the initial electron transverse kinetic energy; the first term on the right is the transverse electron kinetic energy at some point (Y) in the expanded field region, while the final term is the ion kinetic energy parallel to B at point (Y). This last term is what constitutes the desired ion flow. It is produced by an electrostatic field set up by electrons which are accelerated according to Equation (2) in the divergent field region and pulls ions along with them. Equation (3) ignores electron kinetic energy parallel to B because $V_{e\parallel} \approx V_{i\parallel}$, so the bulk of parallel kinetic energy resides in the ions because of their greater masses. For example, if an electromagnetic energy flux of from about 1 to about 10 watts per square centimeter is applied to region R, whose altitude is 115 km, a plasma having a density (N_e) of 10^{12} per cubic centimeter will be generated and moved upward to region R_2 which has an altitude of about 1000 km. The movement of electrons in the plasma is due to the mirror force while the ions are moved by ambipolar diffusion (which results from the electrostatic field). This effectively "lifts" a layer of plasma **12** from the ionosphere and/or magnetosphere to a higher elevation R_2. The total energy required to create a plasma with a base area of 3 square kilometers and a height of 1000 km is about 3×10^{13} joules.

FIG. **3** is an idealized representation of movement of plasma **12** upon excitation by electron cyclotron resonance within the earth's divergent force field. Electrons (e) are accelerated to velocities required to generate the necessary mirror force to cause their upward movement. At the same time neutral particles (n) which are present along line **11** in region $R_1$are ionized and become part of plasma **12**. As electrons (e) move upward along line **11**, they drag ions (i) and neutrals (n) with them but at an angle θ of about 13 degrees to field line **11**. Also, any particulates that may be present in region R_1, will be swept upwardly with the plasma. As the charged particles of plasma **12** move upward, other particles such as neutrals within or below R_1, move in to replace the upwardly moving particles. These neutrals, under some conditions, can drag with them charged particles.

For example, as a plasma moves upward, other particles at the same altitude as the plasma move horizontally into the region to replace the rising plasma and to form new plasma. The kinetic energy developed by said other particles as they move horizontally is, for example, on the same order of magnitude as the total zonal kinetic energy of stratospheric winds known to exist.

Referring again to FIG. **2**, plasma **12** in region R_1 is moved upward along field line **11**. The plasma **12** will then form a plume (cross-hatched area in FIG. **2**) which will be relatively stable for prolonged periods of time. The exact period of time will vary widely and be determined by gravitational forces and a combination of radiative and diffusive loss terms. In the previous detailed example, the calculations were based on forming a plume by producing 0+energies of 2 ev/particle. About 10 ev per particle would be required to expand plasma **12** to apex point C (FIG. **1**). There at least some of the particles of plasma **12** will be trapped and will oscillate between mirror points along field line **11**. This oscillation will then allow additional heating of the trapped plasma **12** by stochastic heating which is associated with trapped and oscillating particles. See "A New Mechanism for Accelerating Electrons in the Outer Ionosphere" by R. A. Helliwell and T. F. Bell, Journal of Geophysical Research, Vol. 65, No. 6, June, 1960. This is preferably carried out at an altitude of at least 500 km.

The plasma of the typical example might be employed to modify or disrupt microwave transmissions of satellites. If less than total black-out of transmission is desired (e.g., scrambling by phase shifting digital signals), the density of the plasma (N_e) need only be at least about 10^6 per cubic centimeter for a plasma orginating at an altitude of from about 250 to about 400 km and accordingly less energy (i.e., electromagnetic radiation), e.g., 10^8 joules need be provided. Likewise, if the density $N_e$is on the order of 10^8, a properly positioned plume will provide a reflecting surface for VHF waves and can be used to enhance, interfere with, or otherwise modify communication transmissions. It can be seen from the foregoing that by appropriate application of various aspects of this invention at strategic locations and with adequate power sources, a means and method is provided to cause interference with or even total disruption of communications over a very large portion of the earth. This invention could be employed to disrupt not only land based communications, both civilian and military, but also airborne communications and sea communications (both surface and subsurface). This would have significant military implications, particularly as a barrier to or confusing factor for hostile missiles or airplanes. The belt or belts of enhanced ionization produced by the method and apparatus of this invention, particularly if set up over Northern Alaska and Canada, could be employed as an early warning device, as well as a communications disruption medium. Further, the simple ability to produce such a situation in a practical time period can by itself be a deterring force to hostile action. The ideal combination of suitable field lines intersecting the earth's surface at the point where substantial fuel sources are available for generation of very large quantitities of electromagnetic power, such as the North Slope of Alaska, provides the wherewithal to accomplish the foregoing in a practical time period, e.g., strategic requirements could necessitate achieving the desired altered regions in time periods of two minutes or less and this is achievable with this invention, especially when the combination of natural gas and magnetohydrodynamic, gas turbine, fuel cell and/or EGD electric generators are employed at the point where the useful field lines intersect the earth's surface. One feature of this invention which satisfies a basic requirement of a weapon system, i.e., continuous checking of operability, is that small amounts of power can be generated for operability checking purposes. Further, in the exploitation of this invention, since the main electromagnetic beam which generates the enhanced ionized belt of this invention can be modulated itself and/or one or more additional electromagnetic radiation waves can be impinged on the ionized region formed by this invention as will be described in greater detail herein after with respect to FIG. **4**, a substantial amount of randomly modulated signals of very large power magnitude can be generated in a highly nonlinear mode. This can cause confusion of or interference with or even complete disruption of guidance systems employed by

even the most sophisticated of airplanes and missiles. The ability to employ and transmit over very wide areas of the earth a plurality of electromagnetic waves of varying frequencies and to change same at will in a random manner, provides a unique ability to interfere with all modes of communications, land, sea, and/or air, at the same time. Because of the unique juxtaposition of usable fuel source at the point where desirable field lines intersect the earth's surface, such wide ranging and complete communication interference can be achieved in a resonably short period of time. Because of the mirroring phenomenon discussed hereinabove, it can also be prolonged for substantial time periods so that it would not be a mere transient effect that could simply be waited out by an opposing force. Thus, this invention provides the ability to put unprecedented amounts of power in the earth's atmosphere at strategic locations and to maintain the power injection level, particularly if random pulsing is employed, in a manner far more precise and better controlled than heretofore accomplished by the prior art, particularly by the detonation of nuclear devices of various yeilds at various altitudes. Where the prior art approaches yielded merely transitory effects, the unique combination of fuel and desirable field lines at the point where the fuel occurs allows the establishment of, compared to prior art approaches, precisely controlled and long-lasting effects which cannot, practically speaking, simply be waited out. Further, by knowing the frequencies of the various electromagnetic beams employed in the practice of this invention, it is possible not only to interfere with third party communications but to take advantage of one or more such beams to carry out a communications network even though the rest of the world's communications are disrupted. Put another way, what is used to disrupt another's communications can be employed by one knowledgeable of this invention as a communications network at the same time. In addition, once one's own communication network is established, the far-reaching extent of the effects of this invention could be employed to pick up communication signals of other for intelligence purposes. Thus, it can be seen that the disrupting effects achievable by this invention can be employed to benefit by the party who is practicing this invention since knowledge of the various electromagnetic waves being employed and how they will vary in frequency and magnitude can be used to an advantage for positive communication and eavesdropping purposes at the same time. However, this invention is not limited to locations where the fuel source naturally exists or where desirable field lines naturally intersect the earth's surface. For example, fuel, particularly hydrocarbon fuel, can be transported by pipeline and the like to the location where the invention is to be practiced.

FIG. 4 illustrates another embodiment wherein a selected region of plasma R_3which lies within the earth's ionosphere is altered to increase the density thereof whereby a relatively stable layer **30** of relatively dense plasma is maintained within region R_3. Electromagnetic radiation is transmitted at the outset essentially parallel to field line **11** via antenna **15** as a right hand circularly polarized wave and at a frequency (e.g., 1.78 megahertz when the magnetic field at the desired altitude is 0.66 gauss) capable of exciting electron cyclotron resonance in plasma **12** at the particular altitude of plasma **12**. This causes heating of the particles (electrons, ions, neutrals, and particulates) and ionization of the uncharged particles adjacent line **11**, all of which are absorbed into plasma **12** to increase the density thereof. The power transmitted, e.g., 2×10^6 watts for up to 2 minutes heating time, is less than that required to generate the mirror force F required to move plasma **12** upward as in the previous embodiment.

While continuing to transmit electromagnetic radiation **20** from antenna **15**, a second electromagnetic radiation beam **31**, which is at a defined frequency different from the radiation from antenna **15**, is transmitted from one or more second sources via antenna **32** into layer **30** and is absorbed into a portion of layer **30** (cross-hatched area in FIG. 4). The electromagnetic radiation wave from antenna **32** is amplitude modulated to match a known mode of oscillation f_3 in layer **30**. This creates a resonance in layer **30** which excites a new plasma wave **33** which also has a frequency of f_3 and which then propogates through the ionosphere. Wave **33** can be used to improve or disrupt communications or both depending on what is desired in a particular application. Of course, more than one new wave **33** can be generated and the various new waves can be modulated at will and in a highly nonlinear fashion.

FIG. **5** shows apparatus useful in this invention, particularly when those applications of this invention are employed which require extremely large amounts of power. In FIG. **5** there is shown the earth's surface **40** with a well **41** extending downwardly thereinto until it penetrates hydrocarbon producing reservoir **42**. Hydrocarbon reservoir **42** produces natural gas alone or in combination with crude oil. Hydrocarbons are produced from reservoir **42** through well **41** and wellhead **43** to a treating system **44** by way of pipe **45**. In treater **44**, desirable liquids such as crude oil and gas condensates are separated and recovered by way of pipe **46** while undesirable gases and liquids such as water, H_2S, and the like are separated by way of pipe **47**. Desirable gases such as carbon dioxide are separated by way of pipe **48**, and the remaining natural gas stream is removed from treater **44** by way of pipe **49** for storage in conventional tankage means (not shown) for future use and/or use in an electrical generator such as a magnetohydrodynamic, gas turbine, fuel cell or EGD generator **50**. Any desired number and combination of different types of electric generators can be employed in the practice of this invention. The natural gas is burned in generator **50** to produce substantial quantities of electricity which is then stored and/or passed by way of wire **51** to a transmitter **52** which generates the electromagnetic radiation to be used in the method of this invention. The electromagnetic radiation is then passed by way of wire **53** to antenna **54** which is located at or near the end of field line **11**. Antenna **54** sends circularly polarized radiation wave **20** upwards along field line **11** to carry out the various methods of this invention as described hereinabove.

Of course, the fuel source need not be used in its naturally-occurring state but could first be converted to another second energy source form such as hydrogen, hydrazine and the like, and electricity then generated from said second energy source form.

It can be seen from the foregoing that when desirable field line **11** intersects earth's surface **40** at or near a large naturally-occurring hydrocarbon source **42**, exceedingly large amounts of power can be very efficiently produced and transmitted in the direction of field lines. This is particularly so when the fuel source is natural gas and magnetohydrodynamic generators are employed. Further, this can all be accomplished in a

relatively small physical area when there is the unique coincidence of fuel source **42** and desirable field line **11**. Of course, only one set of equipment is shown in FIG. **5** for sake of simplicity. For a large hydrocarbon reservoir **42**, a plurality of wells **41** can be employed to feed one or more storage means and/or treaters and as large a number of generators **55** as needed to power one or more transmitters **52** and one or more antennas **54**. Since all of the apparatus **44** through **54** can be employed and used essentially at the sight where naturally-occurring fuel source **42** is located, all the necessary electromagnetic radiation **20** is generated essentially at the same location as fuel source **42**. This provides for a maximum amount of usable electromagnetic radiation **20** since there are no significant storage or transportation losses to be incurred. In other words, the apparatus is brought to the sight of the fuel source where desirable field line **11** intersects the earth's surface **40** on or near the geographical location of fuel source **42**, fuel source **42** being at a desirable magnetic latitude for the practice of this invention, for example, Alaska.

The generation of electricity by motion of a conducting fluid through a magnetic field, i.e., magnetohydrodynamics (MHD), provides a method of electric power generation without moving mechanical parts and when the conducting fluid is a plasma formed by combustion of a fuel such as natural gas, an idealized combination of apparatus is realized since the very clean-burning natural gas forms the conducting plasma in an efficient manner and the thus formed plasma, when passed through a magnetic field, generates electricity in a very efficient manner. Thus, the use of fuel source **42** to generate a plasma by combustion thereof for the generation of electricity essentially at the site of occurrence of the fuel source is unique and ideal when high power levels are required and desirable field lines **11** intersect the earth's surface **40** at or near the site of fuel source **42**. A particular advantage for MHD generators is that they can be made to generate large amounts of power with a small volume, light weight device. For example, a 1000 megawatt MHD generator can be construed using superconducting magnets to weigh roughly 42,000 pounds and can be readily air lifted.

This invention has a phenomenal variety of possible ramifications and potential future developments. As alluded to earlier, missile or aircraft destruction, deflection, or confusion could result, particularly when relativistic particles are employed. Also, large regions of the atmosphere could be lifted to an unexpectedly high altitude so that missiles encounter unexpected and unplanned drag forces with resultant destruction or deflection of same. Weather modification is possible by, for example, altering upper atmosphere wind patterns or altering solar absorption patterns by constructing one or more plumes of atmospheric particles which will act as a lens or focusing device. Also as alluded to earlier, molecular modifications of the atmosphere can take place so that positive environmental effects can be achieved. Besides actually changing the molecular composition of an atmospheric region, a particular molecule or molecules can be chosen for increased presence. For example, ozone, nitrogen, etc. concentrations in the atmosphere could be artificially increased. Similarly, environmental enhancement could be achieved by causing the breakup of various chemical entities such as carbon dioxide, carbon monoxide, nitrous oxides, and the like. Transportation of entities can also be realized when advantage is taken of the drag effects caused by regions of the atmosphere moving up along diverging field lines. Small micron sized particles can be then transported, and, under certain circumstances and with the availability of sufficient energy, larger particles or objects could be similarly affected. Particles with desired characteristics such as tackiness, reflectivity, absorptivity, etc., can be transported for specific purposes or effects. For example, a plume of tacky particles could be established to increase the drag on a missile or satellite passing therethrough. Even plumes of plasma having substantially less charged particle density than described above will produce drag effects on missiles which will affect a lightweight (dummy) missile in a manner substantially different than a heavy (live) missile and this affect can be used to distinguish between the two types of missiles. A moving plume could also serve as a means for supplying a space station or for focusing vast amount of sunlight on selected portions of the earth. Surveys of global scope could also be realized because the earth's natural magnetic field could be significantly altered in a controlled manner by plasma beta effects resulting in, for example, improved magnetotelluric surveys. Electromagnetic pulse defenses are also possible. The earth's magnetic field could be decreased or disrupted at appropriate altitudes to modify or eliminate the magnetic field in high Compton electron generation (e.g., from high altitude nuclear bursts) regions. High intensity, well controlled electrical fields can be provided in selected locations for various purposes. For example, the plasma sheath surrounding a missile or satellite could be used as a trigger for activating such a high intensity field to destroy the missile or satellite. Further, irregularities can be created in the ionosphere which will interfere with the normal operation of various types of radar, e.g., synthetic aperture radar. The present invention can also be used to create artificial belts of trapped particles which in turn can be studied to determine the stability of such parties. Still further, plumes in accordance with the present invention can be formed to simulate and/or perform the same functions as performed by the detonation of a "heave" type nuclear device without actually having to detonate such a device. Thus it can be seen that the ramifications are numerous, far-reaching, and exceedingly varied in usefulness.

I claim:

1. A method for altering at least one region normally existing above the earth's surface with electromagnetic radiation using naturally-occurring and diverging magnetic field lines of the earth comprising transmitting first electromagnetic radiation at a frequency between 20 and 7200 kHz from the earth's surface, said transmitting being conducted essentially at the outset of transmission substantially parallel to and along at least one of said field lines, adjusting the frequency of said first radiation to a value which will excite electron cyclotron resonance at an initial elevation at least 50 km above the earth's surface, whereby in the region in which said electron cyclotron resonance takes place heating, further ionization, and movement of both charged and neutral particles is effected, said cyclotron resonance excitation of said region is continued until the electron concentration of said region reaches a value of at least 10^6 per cubic centimeter and has an ion energy of at least 2 ev.

2. The method of claim **1** including the step of providing artificial particles in said at least one region which are excited by said electron cyclotron resonance.

3. The method of claim **2** wherein said artificial particles are provided by injecting same into said at least one region from an orbiting satellite.

4. The method of claim **1** wherein said threshold excitation of electron cyclotron resonance is about 1 watt per cubic centimeter and is sufficient to cause movement of a plasma region along said diverging magnetic field lines to an altitude higher than the altitude at which said excitation was initiated.

5. The method of claim **4** wherein said rising plasma region pulls with it a substantial portion of neutral particles of the atmosphere which exist in or near said plasma region.

6. The method of claim **1** wherein there is provided at least one separate source of second electromagnetic radiation, said second radiation having at least one frequency different from said first radiation, impinging said at least one second radiation on said region while said region is undergoing electron cyclotron resonance excitation caused by said first radiation.

7. The method of claim **6** wherein said second radiation has a frequency which is absorbed by said region.

8. The method of claim **6** wherein said region is plasma in the ionosphere and said second radiation excites plasma waves within said ionosphere.

9. The method of claim **8** wherein said electron concentration reaches a value of at least 10^{12} per cubic centimeter.

10. The method of claim **8** wherein said excitation of electron cyclotron resonance is initially carried out within the ionosphere and is continued for a time sufficient to allow said region to rise above said ionosphere.

11. The method of claim **1** wherein said excitation of electron cyclotron resonance is carried out above about 500 kilometers and for a time of from 0.1 to 1200 seconds such that multiple heating of said plasma region is achieved by means of stochastic heating in the magnetosphere.

12. The method of claim **1** wherein said first electromagnetic radiation is right hand circularly polarized in the northern hemisphere and left hand circularly polarized in the southern hemisphere.

13. The method of claim **1** wherein said electromagnetic radiation is generated at the site of a naturally-occurring hydrocarbon fuel source, said fuel source being located in at least one of northerly or southerly magnetic latitudes.

14. The method of claim **13** wherein said fuel source is natural gas and electricity for generating said electromagnetic radiation is obtained by burning said natural gas in at least one of magnetohydrodynamic, gas turbine, fuel cell, and EGD electric generators located at the site where said natural gas naturally occurs in the earth.

15. The method of claim **14** wherein said site of natural gas is within the magnetic latitudes that encompass Alaska.

[57] **ABSTRACT**

This invention relates to generation of a Artificial Ionospheric Mirror (AIM), or a plasma layer in the atmosphere. The AIM is used like the ionosphere to reflect RF energy over great distances. A tiltable AIM is created by a heater antenna controlled in phase and frequency. The heater antenna phase shift scans a beam to paint a plasma layer. Frequency is changed to refocus at continually higher altitudes to tilt the plasma layer.

ARTIFICIAL IONOSPHERIC MIRROR COMPOSED OF A PLASMA LAYER WHICH CAN BE TILTED

BACKGROUND OF THE INVENTION

1. Field of the Invention

This invention relates to generation of a Artificial Ionospheric Mirror (AIM), or a plasma layer in the atmosphere. The AIM is used like the ionosphere to reflect RF energy over great distances.

2. Description of the Related Art

In the past, the technique of using the ionosphere as a mirror to reflect radio waves, or RF energy, has given Ham Radio operators the ability to send transmissions over long distances. This technique has also provided radar systems the ability to look "over the horizon." Variations and fluctuations in the ionosphere, however, can render the effectiveness of such communications uncertain. Thus, the desirability of creating controllable plasma layers in the atmosphere for communications purposes has been recognized. See, for example, U.S. Pat. No. 4,686,605 issued to Eastlund and U.S. Pat. No. 4,712,155 issued to Eastlund et al.

Previous experiments directed toward creating plasma layers for communications have suffered from the inability to control the inclination of the plasma layer so that signals could be transmitted and received from various ranges. In other words, while one could create a plasma layer in the atmosphere at a lower altitude than the ionosphere, point to point communications would be limited in range based on the reflection angles of the transmitted and reflected signals.

SUMMARY AND OBJECTS OF THE INVENTION

In view of the limitations of the related art it is an object of this invention to generate a plasma layer that could be angled or tilted with respect to the horizon in order to affect signal transmission range.

The present invention provides a system and method for generating a plasma layer at controlled altitudes and inclinations that acts as an artificial ionospheric mirror (AIM) to reflect RF signals. The AIM increases the range and predictability with which RF energy may be reflected off the AIM for communications purposes. More specifically, a tiltable AIM is created by a heater antenna controlled in phase and frequency. The heater antenna phase shift scans a beam to paint a plasma layer. The heater antenna continually refocuses at a higher altitudes by frequency shifting to tilt the plasma layer.

BRIEF DESCRIPTION OF THE DRAWINGS

Further details of the present invention are explained with the help of the attached drawings in which:

FIG. **1** shows creation of an AIM by a heater antenna and use of the AIM for tracking aircraft and reflecting radio waves.

FIG. **2** shows a typical heater array.

FIG. **3** shows the spacial relationship for a heater array used in defining heater array focusing.

FIG. **4** is a graph showing that power is at its upper bound at the antenna focal point.

FIG. **5** shows generation of plasma by a heater array.

FIG. **6** illustrates generation of a plasma layer by scanning a heater antenna.

FIG. **7** illustrates generation of a tilted plasma layer by scanning and refocusing a heater antenna.

FIG. **8** shows generation of a plasma layer using a heater antenna to scan with a line rather than a point.

FIG. **9** shows the phase corrections to move the antenna focal point from **60** Km to **61** Km.

FIG. **10** shows the frequency corrections to move the antenna focal point from **60** Km to **61** Km.

FIG. **11** is a plot of altitude v. distance location of plasma without frequency chirping.

FIG. **12** is a plot of altitude v. distance location of plasma with frequency chirping.

FIG. **13** shows the power density change after refocusing using frequency chirping .

FIG. **14** graphs the free electron density v. altitude for an unfocused array.

FIG. **15** shows an antenna power pattern without grating lobes.

FIG. **16** shows an antenna power pattern with grating lobes.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

FIG. **1** illustrates the creation and use of An Artificial Ionospheric Mirror (AIM) for tracking aircraft and reflecting radio waves. A heater antenna **1** radiates power causing avalanche ionization or breakdown releasing free electrons in the atmosphere to generate the AIM **2**. The heater antenna **1** is an array which can be used to focus energy at varying altitudes and elevations to tilt the AIM **2** using phase and frequency control. The AIM **2** simulates the ionosphere **3** which is also used to detect "over the horizon targets" **5**. In addition, the AIM **2** can reflect radio signals transmitted from a transmitter **6** to a receiver **7** over long distances.

A typical heater antenna is shown in FIG. **2**. It consists of an array of multiple active radiating elements **10** having their individual phase and frequency controlled from a control module **12**. The radiating element **10** is used here to represent all possible antennas, including, but not limited to, dipoles, slots, small or large horns, log-periodic antennas, large parabolic reflectors, etc.

FIG. **3** shows the spatial relationship for a focused heater array. To have the electric fields from all of the array elements focus, or arrive in phase at a distance R_o in the near field of the array, it is necessary to correct the phase of each element to compensate for the phase delay difference from the center element due to the additional phase path W_{ij}. If R_o is much larger than the maximum D_{ij} in FIG. **3**, then the phase delay can be approximated in wavelength to be:

$$W_{ij}=(D_{ij})^2/(4*R*g) \quad (1)$$

where g is the wavelength of the heater frequency. Equation 1 is referred to as the quadratic phase error. If this error is less than g/8 when the element (i,j) is on the outer edge of the array, then the distance R_o is said to be in the far field of the array.

In order to focus the array at R_o, it is necessary to have several wavelengths of phase error from the outer elements of the array. That is, the term "focus" is used in this context to mean that the electric field from the array is concentrated in a desired spatial region.

FIG. **4** shows the degree of focusing that can be accomplished. This is a vertical pattern of an array whose elements have been phase shifted to focus at 60 Km. The array has 400 elements with a total width and length of 2000 g. The peak of the pattern is determined by the $1/R_o^2$ dependence.

The AIM ionization layer is created by using this focused power to ionize an area in the atmosphere, as shown in FIG. 5. The microwave breakdown of air occurs where free electrons gain enough energy from an electric field to generate additional free electrons until no more can be generated, thereby resulting in avalanche ionization, or breakdown. This causes the generation of a plasma layer **21**. For example, a pulse of power from the heater begins to propagate in the z direction shown in FIG. **5**. As the field propagates, more free electrons are generated. A breakdown point descends vertically from the focal point of the propagating field giving thickness to the ionized layer, or plasma layer, until all ionization stabilizes. This "clamping" creates a thin vertical plasma layer.

Simulation results show that when an array **20** is focused at a point **22**, electric field power peaks at the focal point. Simulation results shows that given a focused microwave source avalanche ionization, or breakdown will occur at a power level 3–10 dB below the focal point power level.

To create an AIM, the heater array is focused at a desired altitude to maximize power at a point and thereby generate plasma. The heater antenna then "scans" the phase of each array element to move the focal point.

FIG. **6** illustrates creation of a noninclined AIM layer. The heater array **30** is first focused at point **31**. The heater array scans horizontally by phase shifting to a point **32** creating an avalanche ionization line **33**. Next, the heater array scans from a point **34** to a point **35** creating another avalanche ionization line **36**. The heater array continues this process to create an ionization plane or AIM layer.

In order to form an inclined AIM cloud, each new ionization line must occur at a slightly higher altitude. By altering the phase or frequency of the array elements, the focal point can be moved up in altitude, as described below.

FIG. **7** illustrates creation of an inclined AIM. The heater array **40** is first focused at point **41**. The heater array scans along the x direction to point **42** to generate avalanche ionization along line **43**. Next, as in creation of a non-inclined AIM, the heater array scans along the x and y directions directly below point **44**. The heater array **40** alters either phase or frequency to refocus to a higher altitude in the z direction to the point **44**. The heater array then scans along the x axis to point **45** to create the avalanche ionization line **46**. The heater array continues this process to create a tilted ionization plane or tilted AIM layer.

FIG. **8** shows that the preferred method of generating a plasma layer uses a heater antenna to scan with a line rather than a point. Scanning using a line is preferred since an AIM can be created in the atmosphere in less time. To create lines of ionization rather than points, a rectangular array **50** is used. In the array **50**, radiating elements are focused only along the plane of the long dimension of the rectangular array, creating a line of ionization **53**. The array is then scanned along the x-y axis and in altitude along the z axis to create another ionization line **55**. More ionization lines are similarly generated to form a tilted AIM layer.

In order to create a tilted AIM it is necessary to refocus the heater array at successively higher altitudes. Moving the focal point by changing the phase of each element of the heater in a very precise manner is not practical. Moving the focal point away from the initial location requires changing the phase on each element. The phase change required is near the rms tolerance level, typically 1 degree. FIG. **9** shows the required phase corrections to move the focal point from 60 Km to 61 km. Elements **5**, **10**, **15**, and **20** have distances 5d, 10d, 15d, and 20d, respectively from the center of the antenna, where d = 25 meters It is clear from FIG. **9** that it is impractical to alter numerous antenna element phases to move the focal point to create tilted patches for AIM applications. 2000 elements may be required here to generate enough power to ionize the atmosphere.

The second method of refocusing is accomplished by first setting the phases of all elements for the initial focal point and then moving the focal point by changing the frequency rather than the phase. This frequency chirping method is less precise, but easier for hardware implementation because precise phases for 2000 elements need not be changed. FIG. **9** shows the required phase corrections to move the focal point from 60 Km to 61 Km. FIG. **10** shows that the focal point can be moved 100 meters by increasing the frequency approximately 1 Mhz. The resulting focal point power levels are not completely optimized, but simulation shows that there is less than a 0.1 db difference between the frequency shifted peaks and those obtained by phasing.

Tilting the AIM using frequency chirping is practical to achieve in a real system. FIG. **11** shows the plasma layer location with no frequency chirping. FIG. **12** shows the plasma location of the same heater creating a tilted AIM by increasing frequency from 550 MHz to 559.375 MHz while scanning horizontally. The result is a smooth patch with a 45 degree inclination.

While it is true that frequency chirping does not achieve the same power as phase focusing at the higher altitude, the difference for small frequency chirps is negligible. FIG. **13** shows actual power density data generated by a 300 MHz heater focused at 70 km with the frequency chirped to 308 MHz.

In the far field region, power meets its upper bound without focusing. For a far field or unfocused array, there is no way to raise the ionization altitude or create a tilted AIM. Ionization takes place at a point where there is enough power to initiate breakdown and where there is low enough neutral density (i.e. pressure). This usually occurs between 40 and 50 km altitude as shown in FIG. **14**. Consequently, a near field focused antenna is required to create a controlled AIM.

The focused pattern is a picture of constructive and destructive interference of the fields from the elements of the array. Other interference positions, or grating lobes, outside the focal point occur when some of the array elements add up in phase. The power of grating lobes can be kept below that of the main lobe, or focal point, by having a large number of elements in the array and spreading them out over the array aperture. This is called thinning the array. For square arrays having 400 elements or more grating lobes can be kept down by 20 db or more from the focal point.

The degree of focusing depends on the ratio of focal range to aperture size. The half power width from peak "V" can be approximated as:

$$V = 2*g*(R_o/L)^2 \qquad (2)$$

where L is the length of the array which is assumed square for equation 2. The power gradient at the half power point "grad(P)" can be approximated as:

$$grad(P)=10/V(db/meter) \quad (3)$$

For an AIM it is desirable that the power gradient be high because this directly determines the gradient of the electron density of the generated ionized cloud. The electron density must be high to avoid RF losses caused by absorption. Hence V be small, preferably less than 2 Km. A heater frequency of 300 MHz and a focal distance of 70 Km would project an aperture size greater than 2 Km. Note in equation 2 that array size scales with the square root of frequency.

Since a near field antenna is required, the near field of the heater antenna may be required to extend to reach distant points. This is accomplished by increasing the array size. It may not be economically feasible to fill this entire aperture with elements, hence a thinned array is utilized.

If a thinned array had its elements uniformly distributed, there would be many grating lobes in the radiation pattern of the array. These grating lobes can be eliminated by randomly spacing elements. However, random spacing puts power from the grating lobes into the average side lobe level. If no new elements are introduced when the aperture is increased, then the peak power of the main lobe remains constant and the main lobe receives less of the total power as its beamwidth decreases. In order to preserve the efficiency of the heater array, grating lobes must be utilized in creating the AIM cloud or the array can not be heavily thinned. FIG. **15** shows an array with uniform spacing having grating lobes. FIG. **16** shows an array with randomized spacing which eliminates the grating lobes.

Although the invention has been described above with particular reference to certain preferred embodiments thereof, it will be understood that modifications and variations are possible within the spirit and scope of the appended claims.

What is claimed is:

1. A method for generating an AIM, comprising the steps of:

(a) creating avalanche ionization in the atmosphere using a heater antenna;

(b) refocusing said heater antenna to alter the altitude of said avalanche ionization by frequency shifting said heater antenna; and

(c) scanning said heater antenna to paint an avalanche ionization layer.

2. A method for generating an AIM as claimed in claim **1** wherein said heater antenna is focused in the near field.

3. An apparatus for generating an AIM comprising:

(a) a phased array heater antenna which is focused at an altitude to cause an avalanche ionization area to be created in the atmosphere;

(b) means for controlling frequency of individual radiators of said phased array heater antenna to

refocus said altitude of said avalanche ionization area; and

(c) means for controlling phase of the individual radiators to scan said phased array heater antenna.

4. An apparatus for generating an AIM as claimed in claim **3** wherein said phased array heater antenna is focused to cause said avalanche ionization area to be substantially a line.

5. An apparatus for generating an AIM as claimed in claim **4** wherein said means for controlling phase moves said line substantially at a constant altitude and said means for controlling frequency moves said line to different altitudes.

6. An apparatus for generating an AIM as claimed in claim **4** wherein said phased array heater antenna is a rectangular array and said line is formed parallel to a long dimension of said rectangular array.

7. An apparatus for generating an AIM as claimed in claim **3** wherein said phased array heater antenna is focused to cause said avalanche ionization area to be substantially a point.

8. An apparatus for generating an AIM as claimed in claim **7** wherein said means for controlling the phase moves said point substantially at the same altitude and said means for controlling frequency moves said point to different altitudes.

9. An apparatus for generating an AIM as claimed in claim **3** wherein said phased array heater antenna is focused in the near field.

10. A method of generating an AIM comprising the steps of:

(a) focusing a phased array heater antenna at an altitude to cause an avalanche ionization area to be created in the atmosphere;

(b) controlling the frequency of individual radiators of said phased array heater antenna to refocus said altitude of said avalanche ionization area;

(c) controlling phase of the individual radiators to scan said phased array heater antenna.

11. A method of generating an AIM as claimed in claim **10** wherein said step of focusing causes said avalanche ionization are to be substantially a line.

12. A method of generating an AIM as claimed in claim **11** wherein said step of controlling phase moves said line substantially at a constant altitude and said step of controlling frequency moves said line to different altitudes.

13. A method of generating an AIM as claimed in claim **11** wherein said phased array heater antenna is a rectangular array and said line is formed parallel to a long dimension of said rectangular array.

14. A method of generating an AIM as claimed in claim **10** wherein said step of focusing causes said avalanche ionization area to be substantially a point.

15. A method of generating an AIM as claimed in claim **14** wherein said step of controlling phase moves said point substantially at the same altitude and said step of controlling frequency moves said point to different altitudes.

16. A method of generating an AIM as claimed in claim **10** wherein said step of focusing is performed in the near field.

US Air Force Admits They Can Control Weather

JUNE 6, 2015 | ECLINIK LEARNING | 66 COMMENTS

The US Air Force and DARPA would like us to believe that they have stopped using HAARP in Alaska for research and experiment. Even then, we all know that there are other HAARP systems out there in the form of radar communication and surveillance systems that are rigged on top of mobile platforms that are deployable anywhere in the world.

All they need to do is twist a button to change the frequency to microwave range and increase transmission power enough to reach and heat up the atmosphere above the target.

Unnatural weather patterns suggest HAARP is still here.

Air Force Bombshell: Admits They Can Control Weather – HAARP

(https://eclinik.files.wordpress.com/2015/03/haarp-28.jpg)

While HAARP and weather control has been called a conspiracy theory by the mainstream media and government officials, during a Senate hearing on Wednesday, David Walker, deputy assistant secretary of the Air Force for science, technology and engineering, dropped a bombshell (http://www.adn.com/2014/05/14/3470442/air-force-prepares-to-dismantle.html?sp=/99/100/&ihp=1) in answer to a question asked by Lisa Murkowski in relation to the dismantling of the $300 million High Frequency Active Auroral Research Program in Gakona this summer.

Walker said this is "not an area that we have any need for in the future" and it would not be a good use of Air Force research funds to keep HAARP going. "We're moving on to other ways of managing the ionosphere, which the HAARP was really designed to do," he said. "**To inject energy into the ionosphere to be able to actually control it. But that work has been completed.**"

climatecentral.org

Many believe HAARP was created and has been used for weather control, with enough juice to trigger hurricanes, tornadoes and earthquakes and comments such as this bring about the question of whether conspiracy theorists are more on target than anyone has admitted to date.

This is not the first time a public official has acknowledged that HAARP and weather control is not only possible, but has been and continues to be, used as a "super weapon," as evidenced by a statement in 1997 by former U.S. Defense Secretary William Cohen (http://www.cheniere.org/correspondence/022501.htm), where he said *"Others [terrorists] are engaging even in an eco-type of terrorism whereby they can alter the climate, set off earthquakes, volcanoes remotely through the use of electromagnetic waves… So there are plenty of ingenious minds out there that are at work finding ways in which they can wreak terror upon other nations…It's real, and that's the reason why we have to intensify our [counterterrorism] efforts."*

Is it still just a conspiracy theory if public officials admit it is true?

Watch the question and answer session below:

source (http://woundedamericanwarrior.com/air-force-bombshell-admits-they-can-control-weather-haarp/#) »

Are they really dismantling the Alaska based HAARP?

How about the floating HAARP transmitters masquerading as mobile radars used in the Philippines?

The US Air Force and DARPA would like us to believe that they have stopped using HAARP in Alaska for research and experiment. Even then, we all know that there are other HAARP systems out there in the form of radar communication and surveillance systems that are rigged on top of mobile platforms that are deployable anywhere in the world.

All they need to do is twist a button to change the frequency to microwave range and increase transmission power enough to reach and heat up the atmosphere above the target."

[57] **ABSTRACT**

A method and apparatus for altering at least one selected region which normally exists above the earth's surface. The region is excited by electron cyclotron resonance heating to thereby increase its charged particle density. In one embodiment, circularly polarized electromagnetic radiation is transmitted upward in a direction substantially parallel to and along a field line which extends through the region of plasma to be altered. The radiation is transmitted at a frequency which excites electron cyclotron resonance to heat and accelerate the charged particles. This increase in energy can cause ionization of neutral particles which are then absorbed as part of the region thereby increasing the charged particle density of the region.

   You carry a "HIGH" top secret security clearance? That in itself lends to you know nothing about security clearance. And secondly, even if you DO have some level of a security clearance, that does not give you knowledge of every program in the United States. Gimme a break dude. That is laughable.

   I agree with you Peggy. They have over 2 dozen FEMA DEATH Camps on American Soil, with 40 Million Coffins ready. We have ISIS Terror Compounds as well,.. I believe it's 35 now. They are all armed and ready for Obama to give them the word to attack. There are over 2200+ Mosques in America – the one's that have been raided, Law Enforcement found tunnels under the Mosques leading to massive amounts of Guns, Rockets, Bombs,.. I'm more than positive every Mosque, No go zone and individual homes that these "refugees" stole,… Are all Armed. Obama and Clinton made sure they were. The ultimate goal is to DEPOPULATE 3 Billion lives in the Western World. They will allow 500 Million to stay alive – which in turn they will be either sex slaves for the women and children, and labor for the able bodied men. Speak up and get this out – with Clinton wanting to bring in 65,000 more and forecasting 100,000 more each year – even if we don't have what's already here causing Destruction on Epic Proportions – Look at Sweden, France, Germany, London, Australia,..etc – you just can't look at the developments happening and by now, haven't figured out that these "Peaceful Refugees" are Terrorist Soldiers with one intention, to kill all Western Civilization and and turn the world into a Islam/Muslim place where their Barbaric Sharia Law will rule. Sharia Law will put women especially at the worst situation of all,.. they will be downgraded to below a rat, beatings are within the law, Rapes and "Honor Killings" will be enforced. If you get "accused" of doing anything, you can be hung, stoned to death, burned to death, beheaded,.. what ever they feel like doing – they will do it without even 1 second of hesitation. Girls 12 – up will more than likely be forced to marry one of these Soldiers, who will then beat, rape, belittle and maybe even killed. Boys – Muslims are Pedophiles, they use boys for pleasure there is no age range as they have killed children as young as a few weeks. They also make arranged marriages for the young girls, toddlers actually – usually 4 and up, where in a lot of cases, they end up with a man 3 – 5 times her age. Unfortunately they are brutally raped and sodomized to the point of death on that very marriage night. If they manage to live – their reproductive functions are very likely destroyed. If they cannot use you to have babies,.. they will probably get sold into sex slavery and will eventually die. From what I understand about the Agenda – they are going to take all the little children from families and be raised by the Government. Those child care facilities are more than likely going to be run by men and women who are very disturbed and are Pedophiles. You can figure out what's in store for those poor babies. Men will be for the most part slaughtered. The one's allowed to live – slaves. If you look up FEMA Executive orders – you will see that you are being run by the Government – they can displace you, take your home, car, anything you cherish and probably throw you in a FEMA DEATH

Camp and or killed,.. they can do this for NO particular reason,.. it's you with the clothes on your back. You will no longer be in charge of what you eat, drink or amounts of it. They will enforce MANDATORY "vaccines" which will be poison in some form. This is no joke – this is happening. Think about it,.. does bringing in 65,000 more of these people that want us all dead, make any sense? To a SANE person – of course not. Obama and Clinton are not on our side. Look up Agenda 21 Depopulation. All of the politicians, leaders, etc. that are FOR OPEN BORDERS are all corrupt and under the impression that they will be immune to being a part of the Depopulation amount of 3 Billion that must be exterminated. They aren't, once they have done what Obama and Clinton wants, they have no use. They are dead to. (those people deserve it). Well my friend – I will Pray to God for GOOD to win over EVIL, please do the same. We are at the point of TRUST NO ONE. Never let anyone take your weapons, if you see someone that looks shady – SHOOT. You Must Profile people now. Don't wait til' they pound down your door – SHOOT. God Bless the World! In Jesus name AMEN. Pray friend.

To the best of my knowledge, the ionisphere only carries charged particles which affect how radio waves are reflected. I'm not aware of any way of controlling the weather with this. There may be some edge cases where clouds can be created or moved a bit with energy from radars / microwave, but that's not really that much, and ultimately, you aren't getting as much back as you put in.

The layers surrounding our planet are heated by the charged particles and that creates weather effects. The patents for this technology demonstrate many many militarily “useful” effects, including opening unique communication channels while simultaneously blocking other communication channels, generating large area brainwave entrainments, a radar-like ability to show activity deep in the ocean and even underground, and more effects. Look into it, it’s interesting.

Yes that’s correct. Weather is created in the lowest layer called the troposphere where the clouds exist and weather conditions are formed. I learned this in high school in a meteorology class.

people have eyes but cant see and people have ears but cant hear do a little research and deploy yourself as a a disciple
if life is such an amusement then pick your side
faith is he who dont lie and the devil meaning evil cant stand the beginning nor the end (genisis and revalation)
so if life is hidden from us its because of our actions where not corrected so we end up w/ deceiving people
we must reconstruct our lives yet if people would buy into their future like counting your

blessings before they hatch we could possibly live with god (god is the future) think about it the word convenience is rude and their is so much evil behind that word (i dont want to get into that) but patience opens a view of opportunities
understand the american dream has been controlled for years
if its as simple as feeding a cow grass why not let domestic animals roam they where put here for what to own (wrong)
weve been owned and mentally controlled (a pattern has occured)
we the people have explored and found electricity awesome right
understanding it has been difficult for some people yet we choose to hang it over our heads like candy we want it but dont care who made it so convenient right
FYI if u didnt know static electricity pulls water (plastic materials is the moon possibly and wool is mostly the earth trees,life) no one really knows what the moons really made of but i do know the moon pulls the water like static would so thats my best answer molecules on the surface
so the phenomenon lives on as our lives could be at jeopardy
so much $ has been invested in this ask donald trump his uncle and father met nikola tesla also trump family was involved in creating a static generator (van-degraaff generator)possible controlling the storm would be a better generator my brother and i have ideas on that conversation w/some more understanding and info of errors its like starting at the bottom w all previous mistakes to happen again government info must be replayed because getting info from them is like history replaying itself hidden from the main agenda us the people if i could create a storm wouldnt u think some idiotic person try it (hidden from us isnt good and us knowing isnt good either)idk im not a

The Air Force gave HAARP to the University of Alaska. They recently had an open house for the public: http://gi.alaska.edu/facilities/haarp

And, yes, we have been manipulating the weather for awhile. One civilian example is LA. They have been cloud seeding since the 1950s, per The LA Times: http://www.latimes.com/local/lanow/la-me-ln-l-a-officials-seeded-clouds-during-el-nino-storm-in-hopes-of-more-rain-20160308-story,amp.html

Thats the truth…they arent going to admit to the fact that the big hurricane that hit Mexico this last yr. 2015 and was said to be the biggest hurricane ever to hit this planet , i live in Wadhington State and the day before it hit Mexico the chemtrails in the sky here was so massive , it was unbelievable. So at that point i knew the haarp had been used and im convinced they caused the hurricane. Ive been studing the HAARP. For over 20 yrs. Its a reversed radio waves Antenna that DOES mess with the weather as well as can single out a person and mess with their mind. Seriously there is also one in Florida too. … Hurricane Catrina… so I say to Our Goverment, who do you think you are messing with. MOTHER NATURE??? Admit what you assholes have done and let the chips fall where they may.

Wake up AMERICA.. Its time to take action.

   Walker said "We're moving on to other ways of managing the ionosphere, which the HAARP was really designed to do"

   The Air Force admits that HAARP affects the ionosphere, what has this to do with weather control.

HAARP is a means to manage the ionosphere, not the troposphere.
The ionosphere is the layer of the Earth's atmosphere that is ionized by solar and cosmic radiation. It lies 75-1000 km (46-621 miles) above the Earth.

The troposphere is the lowest layer of Earth's atmosphere and site of all weather on Earth. The troposphere is bonded on the top by a layer of air called the tropopause, which separates the troposphere from the stratosphere, and on bottom by the surface of the Earth.

All weather occurs only in the troposphere.

HAARP affects only the ionosphere.

   The distance traveled by an electrical signal depends on its electrical pressure [V], i.e. the higher the voltage [V] the farther the distance reached by that signal.

   If your 3-volt remote control could change your TV channel it doesn't mean you can change your neighbor's TV channel across the road.

   If HAARP could reach the ionosphere, why not the troposphere which, as you said, is nearer?

   All the HAARP operator needs to do is lower the transmission voltage from 200 million volts to 100 or 50 million volts by twisting a single knob.

A Tesla "death ray" may need a different frequency with the same amount of voltage as HAARP, but your car's spark plug only needs 40kv to 100kv to force that quarter inch gap of atmosphere to become conductive.

By comparison, FM radio transmitters broadcast at 50kw power while HAARP is about 4 billion watts according to its patent.

Yes, it has caused the drought here. Check out satellite images of the Pacific by the west coast. We are bombarded, then it drifts in — along with the streams of chemicals they spray on us in our mountains and valleys. I guess they've decided to create rain for us, because it's been pouring for a week or more, which we need…but it also makes us wonder wtf is raining down on us?!! People laugh at me and others for sharing this stuff. Whatever. Keep sleeping, sheep. Keep drinking your fluoride water. Keep watching that Fox "news" like my asshole neighbor and friends and family do. The attacks no longer phase me. Screw them all. This whole thing goes deeper than just chemtrails and weather manipulation. All of us now have metallic nanoparticles inside of us. Do your ears ring constantly? Loudly? Mine do, and have for a long time. It's like a high-pitched radio frequency that is incessant! Jump down that rabbit hole if you dare, but I warn you — it will blow your freaking mind what they have in store for us.

    Uhh "high top secret security clearance" means jack shit if you dont have what the military calls the need to know. You are only allowed the information that is top secret to the level that allows you to get your job done. Top secret clearance does not mean you all the sudden know all of the top secret info. How do I know? Well not only do they tell us this I can also say so because I have a top secret clearance. Theres no one waiting to brief you on everything going down on every level as soon as you get a clearance. Its a need to know basis.

I'm not ameteorologist, but I am familiar with enough physics that I find this merits questions. First: define "controllable." Even if there were some means of influencing a hurricane's path, they wouldn't just be able to reverse it, because of inertia. Second: define "control." When people say "control the weather," it conjures up images of TPTB deciding just how the weather should act that day, and implementing it. This ability to micromanage is not possible: for one, the Navier-Stokes equations, which model fluid flow, by necessity also model turbulence (it would make a lousy model if they didn't describe all known phenomena). This means the equations (which, by the way, haven't been solved) have chaotic solutions, and so we can't always even predict the result of a given action. Thisis why I find the language misleading; but "influence the weather" doesn't sound nearly so ominous, does it?

Weather modification has been used for warfare purposes since at least the 1960's – Operation Popeye: cloud-seeding was used over the Ho Chi Minh trail in Vietnam to slow down the enemy and that's not even the tip of the iceberg. It's all there in the declassified documents for anyone who has a brain to see. It's not a "conspiracy theory" – it's been openly acknowledged for decades.

    Hey oscar,

    These radar installations and mobile ship radar platforms are what is creating and directing the direction of the hurricanes. Not saying every event is man made, but lots have questionable aspects and can be linked to the x band ship being deployed to the Philippines as there are 2 HAARP installations in Japan. The patent uses three beams to steer the storm cell.

Michael, ultimately influence and control are virtually the same- it's more so the context that you view the term "control". The weather works on its own, just like your mind isn't telling you to breathe. The point is that if they would like a "natural" event to Happen, they can make it happen – when and where. Sure they can't turn a hurricane around, but why would you even try? How would that look natural lol. Also the point is to create a weakened country so they need to lean on ol Uncle Sam and their friends at the world bank and IMF. Similar events to this recently would be the sudden earth quake that struck China's super computer…. wow, how fortunate for the USA if the worlds fastest super computer(China's) were critically damaged or even just taken offline for awhile

WEATHER CONTROL BY ARTIFICIAL MEANS

Heinz W. Kasemir, Neptune, and Helmut K. Weickmann, Interlaken, N.J., assignors to the United States of America as represented by the Secretary of the Army

Filed Sept. 23, 1964, Ser. No. 398,816
3 Claims. (Cl. 239—2)

The invention described herein may be manufactured and used by or for the Government for governmental purposes, without the payment of any royalty thereon.

The present invention relates to weather control and more particularly to a method and means for changing the natural electric charge distribution or pattern of thunderstorms and thereby controlling the discharge of lightning. Depending on the way in which the charge distribution is modified, lightning strokes may be inhibited in cases where the natural conditions would normally result in lightning and in other cases the natural charge distribution which would not normally result in lightning may be modified to induce lightning discharge. According to the invention, the natural space charge distribution of the thunderstorm is modified by introducing in regions of strong electric potential gradient a plurality of needle-shaped conductors. The interaction of the electric field and the pointed conductors will produce point discharge or corona. The corona discharge produces a large number of positive and negative ions which are capable of supporting heavy currents needed to hold the electric field below that value at which lightning discharge is initiated. In other cases, the change in the natural space charge distribution caused by the introduction of these conductors can result in an increased electric field gradient in adjacent regions of the atmosphere which will tend to induce lightning discharge in these adjacent regions.

It is therefore an object of the invention to modify atmospheric electric conditions by artificial means.

It is a further object of the invention to control lightning discharge by the seeding of a selected area of the atmosphere with a plurality of needle-shaped conductors.

These and other objects and advantages of the invention will become apparent from the following detailed description and drawing, in which

FIGS. 1 and 2 are pictorial diagrams of two different types of atmospheric conditions to which the invention may be applied.

In FIG. 1, the thundercloud 5 floats in the atmosphere above the earth 3. The cloud contains areas of positive and negative electrical space charge 7 and 9, respectively. A certain electric field gradient will exist in the region between these space charges depending on the spacing thereof and the charge magnitude. Under natural conditions, prior to the lightning discharge, the electric field will cause a limited amount of ionization or glow discharge in the region between the space charges 7 and 9 by corona discharge from precipitation particles in this region. This natural ionization will support or carry electrical current between the charged areas 7 and 9 and therefore will tend to discharge or bleed off the space charge. However, because of the generally spherical shape and the small size of the precipitation particles, they are not efficient ion producers. If the natural rate of charge buildup of areas 7 and 9 is greater than the charge dissipation due to the natural ionization, the potential gradient will increase until intracloud lightning occurs which of course substantially neutralizes the space charge. In accordance with the invention, the region between the space charges 7 and 9 is seeded with needle-like conductors 12. These conductors are made at least 1 centimeter in length and are therefore substantially larger than the natural precipitation particles. The size of the conductors together with their needle-like shape make them more efficient producers of atmospheric ionization due to corona discharge than the natural precipitation particles. The increased ionization in effect raises the atmospheric conductivity to such an extent that the space charge can be bled off or neutralized as fast as it naturally builds up. The result is a slow, controlled dissipation or neutralization of the cloud space charge rather than the rapid and sometimes destructive lightning stroke.

FIG. 2 illustrates a situation in which ground lightning strokes as well as intracloud strokes are possible. In thundercloud 14 is an area 13 of positive charge, a larger area 15 of negative charge and a somewhat smaller area 17 of positive charge near the lower boundary of the cloud. Under natural conditions a small intracloud stroke may start between areas 15 and 17 and may grow until it reaches ground, becoming a ground stroke, thereby carrying negative charge from region 15 to earth and consequently tending to dissipate the area of negative charge. If, however, an intracloud lightning stroke takes place first between positive area 13 and negative area 15, the negative charge may thereby be dissipated to such an extent that no ground stroke will be possible. Thus the intracloud strokes between areas 13 and 15 will use up the negative charge of 15 and thereby lessen the probability of ground strokes. By seeding the region between 13 and 15 with a plurality of needle-shaped conductors 12, the intracloud lightning will be inhibited as explained in connection with FIG. 1 and this will leave a larger negative charge at region 15 which is then available for producing ground strokes. If it is desired to inhibit instead of induce ground strokes, the region between space charge areas 15 and 17 would be seeded with the needle-like conductors. Also, by seeding both of the above-mentioned regions, both ground and intracloud strokes would be inhibited.

The needle-like conductors 12 may comprise metallized nylon threads of from 1 centimeter to 1 inch in length. The metallized nylon is lighter than solid metal needles of the same size and therefore will have a smaller terminal velocity and will remain in the air longer than would all-metal conductors. The conductors may be dispensed at the proper place in the thundercloud by an airplane or a rocket after measurements have been made to determine the most advantageous place for seeding. In order to achieve the desired results, it is necessary that at least several million of these conductors be seeded in each thundercloud.

The present invention may be put to several practical uses. For example, forest fire prevention, reduction of radio interference due to lightning, or as a tactical military weapon for either harassing the enemy or protecting friendly forces from adverse weather conditions.

While the invention has been described in connection with an illustrative embodiment, the principles disclosed herein are of general application; hence the invention should be limited only by the scope of the appended claims.

What is claimed is:

1. The method of inhibiting lightning discharge comprising the seeding of a region between two areas of opposite type electric space charge with a plurality of metallized nylon threads, said nylon threads being at least one centimeter in length.

2. The method of controlling lightning discharge comprising increasing the natural rate of ionization in a region of high electric field by the seeding of said region with a plurality of metallized nylon threads, said nylon threads being at least one centimeter in length.

3. The method of inducing ground lightning strokes from a thundercloud which includes an area of negative electric charge with areas of positive electric charge above and below said negative electric charge, comprising, inhibiting intracloud discharge in the region between said area of negative electric charge and the upper one of said areas of positive electric charge by seeding said region with a plurality of metallized nylon threads, said nylon threads being at least one centimeter in length.

TRAPPED ELECTROMAGNETIC RADIATION COMMUNICATIONS SYSTEM

Mario D. Grossi, Cambridge, Mass., and Pietro P. Lombardini, Philadelphia, Pa., assignors to Raytheon Company, Lexington, Mass., a corporation of Delaware

Continuation of application Ser. No. 308,172, Sept. 11, 1963. This application Jan. 11, 1968, Ser. No. 697,244

Int. Cl. H04b *7/00*

U.S. Cl. 343—100 **57 Claims**

This invention relates to communication systems and more particularly to the use of trapped electromagnetic radiation to provide an over the horizon long distance communications network or system.

This application is a continuation of application Ser. No. 308,172 filed Sept. 11, 1963, now abandoned.

Ever since the advent of the radio, various attempts have been made to provide a long range communications system. During the World War I era attempts were made to obtain a reliable world wide communications system utilizing very low frequencies, but due to atmospheric noises and bandwidth limitations, more desirable techniques were required. In more recent years, radio propagation over long distances has been attempted by systems employing "one hop" or "bounce" reflective techniques for scattering V.H.F., U.H.F., and S.H.F. signals. These particular systems have required the use of large amounts of power in order to obtain reception at distant points. Additionally, scattering techniques have suffered from the occurrence of atmospheric instabilities which have caused periodic fading of the transmitted signals. Although scattering techniques have been applied successfully over relatively short distances, such as between the continent of Europe and islands in the Mediterranean, and additionally in Alaska and Northern Canada, long distance communications have not been possible.

Other global communication systems not relying on ground based links have also been attempted. For example, the Telstar orbiting satellite and the orbiting satellite communications system have been proposed as a solution to this problem. Although Telstar has proved that a global communication system is feasible, utilizing an orbiting satellite or a group of orbiting satellites, these systems are quite costly, particularly due to the requirement of at least forty orbiting satellites in order to obtain coverage of the entire world. Additionally, problems of reliability of the repeater equipment utnlized in the satellites will necessitate that additional repeater satellites be periodically placed in orbit as a substitute for an inoperable satellite. Additionally, these satellite systems rely on basically a "one hop" line-of-sight technique between two points, and thus forty satellites are required as a minimum for complete world wide coverage.

Further, "one hop" reflective long distance communication systems have been proposed utilizing a ground created reflective zone or layer of an ionized atmosphere. This reflective layer could be obtained using seeding techniques or possibly by the injection of neutrons to form a reflective cloud in the atmosphere. In spite of the fact that communications have been successfully attempted utilizing seeding for "one hop" point-to-point over the horizon reflective communications links, seeded ionized clouds have been difficult to control, particularly due to the sun's adverse effect. Although all the aforementioned systems have had some success, either their cost or complexity has produced a requirement for a more inexpensive and reliable system to obtain world wide communications.

Accordingly, it is the principal object of this invention to provide a new, useful, and improved highly reliable world wide communications system.

Another object of this invention is to provide an over

the horizon communications system which utilizes a waveguide duct in the ionosphere to trap electromagnetic radiation.

Still another object of this invention is to create an electromagnetically generated ionized cloud to provide a means for injecting electromagnetic radiation into an ionospheric waveguide duct.

A further object of this invention is to provide a means for extracting electromagnetic radiation trapped within an ionospheric waveguide duct.

In accordance with the communications system of this invention, electromagentic radiation is artificially injected into and trapped within an atmospheric waveguide duct. The trapped radiation then propogates within said atmospheric waveguide duct. The trapped radiation then propogates within said atmospheric waveguide duct around the earth. Devices positioned around the earth's periphery are utilized to receive a portion of trapped radiation either by detecting radiation scattered by natural or artificially generated scaters positioned within the waveguide duct.

Other features and objectives of the communications system of this invention will become apparent from the following description taken in conjunction with the following drawings, wherein:

FIG. 1 illustrates schematically a communications system following the principals of this invention including means for generating an artificial scatterer to inject electromagnetic radiation into an ionospheric waveguide duct, and means for receiving a portion of said radiation reflected by natural scatterers.

FIG. 2 illustrates a top plan view of a configuration of an antenna for generating an artificial scatterer.

FIG. 3 is a side elevational view of one of dipole elements of the antenna of FIG. 2.

FIG. 4 illustrates schematically the transmitter and the dipole antenna arrangement for the legs numbered **53** and **54** of the antenna of FIG. 2.

FIG. 5 illustrates schematically the transmitter and the dipole antenna arrangement for the legs numbered **51** and **52** of the antenna of FIG. 2.

FIG. 6 illustrates schematically a means for properly phasing the output radiation from the antenna of FIG. 2 in order to generate an artificial scatterer positioned within the ionosphere.

FIG. 7 is a pictorial representation of the earth surrounded by ionospheric layers for the purpose of explaining the presence of ionospheric waveguide ducts.

FIG. 8 is a schematic diagram of the communications system of this invention including means for generating an artificial scatterer to extract electromagnetic radiation from an ionosphereic waveguide duct; and

FIG. 9 is a side schematic view of an ellipsoid antenna which could be used to generate an artificial scatterer within the ionosphere.

FIG. 1 illustrates a long distance communications system following the principles of this invention and which comprises a transmitter **11** disposed at a point on the earth **10**. The transmitter **11** will be described in conjunction with an explanation of FIGS. 4 and 5. Transmitter **11** provides electromagnetic energy to antenna **12**. Antenna **12** then focuses this energy or radiation, shown as arrows **13**, to form an ionized cloud or scatterer **14**, within the ionospheric region of the atmosphere. A suitable antenna for generating the ionized cloud **14** will be described at a later time in conjunction with the explanation of FIGS. 2, 3, 4 and 5 of the accompanying drawings. The ionized cloud **14** is shown positioned slightly above the ionospheric bottom layer **20**, but substantially below the F_2 layer **23** of the ionospheric region.

The ionized cloud **14** is believed to be generated in the following manner: electrons that already exist in the ionospheric region of the upper atmosphere are accelerated by electromagnetic radiation which is focused from the ground. These electrons are accelerated by the radiation to a degree such that their kinetic energy reaches the level needed for the occurrence of ionizing collisions. Cloud **14** is a result of these ionizing collisions. Scattering from this cloud takes place due to the discontinuity between this zone of enhanced ionization and the surrounding medium. The shape and the properties of the scatterer can be adjusted by controlling the properties of the antenna used, the amount of power provided by the antenna, and the phase of the energy emitted by various portions of the antenna. For example, the preferred embodiment of this invention utilizes a transmitter **11** and antenna **12** operating at a frequency of 50 megacycles, and which provides 26 megawatts of peak power and 260 kilowatts of average power. Antenna **12** focuses the energy to produce a cloud **14** approximately 80 kilometers above the earth's surface. The ionized cloud formed has a mean width of approximately 15 meters and a length of approximately 60 meters. Due to the focusing, the ionized cloud has a shape which comes to a point at its greatest distance from the earth's surface and tapers in the manner of a cone at its widest point. The ionized cloud of this invention also has a variation of the electric field in the cloud versus the height from the antenna which is positive. The antenna used is in a near-field arrangement. In other words, with increasing distance in the resulting cloud **14** there is an increasing field. This does not happen with an unfocused antenna of the far-field type. An unfocused antenna has a radiation pattern which spreads at greater distances from the antenna and its electric field decreases with increasing range. In our case $dE/dh>0$ where E is the E field vector and h is the distance from the antenna above the earth's surface. It is to be noted that the life of our scatterer or cloud persists essentially as long as the ground transmitter is on. This constitutes a basic advantage with respect to any other suggested artificial scatterer, such as that which could be produced by seeding. Accordingly, this system utilizing an ionized cloud which is generated from the earth and which is controllable from the earth is highly superior to any technique which is completely out of the control of the operators.

Referring once again to FIG. 1, a transmitter **30** is shown for providing a communications signal which is to carry information from a point somewhere on the earth's periphery which is in proximity to transmitter **11**. The transmitter **30** could be any of the common A.M. communication transmitters, such as those which operate in the M.F., V.H.F. and H.F. frequency bands. The transmitter **30** provides this communication signal to antenna **31**. The antenna **31** is of a directional type in order that the communication signal can be directed towards the ionized cloud or artificial scatterer **14**. Directional antennas, such as rhombic or Yagi, could be utilized for this purpose. Assume now that the transmitter **30** provides a 20 megacycle communications signal having a 500 kilowatt peak output power to the antenna **31**. This signal will then be directed as shown by the arrowed lines **32**, and be refracted off the ionized cloud or scatterer **14**. This signal **32** will be directed through the ionospheric waveguide duct, due to a refractive electron layer **21** which curves spherically around and is concentric with the earth's periphery. This refractive layer **21** causes the communication signal **32** to be trapped within an ionospheric waveguide duct which has the refractive layer **21** as its upper boundary, substantially the ionospheric bottom as its lower boundary, and which is concentric with the earth's periphery. The explanation of the presence of this refractive layer and the duct will be given at a later time in conjunction with a description of FIG. 7.

Assuming now a receiving station, such as receiver **40** and antenna **41**, located at a site which is at a long distance from transmitter **30**, is required to receive information transmitted by transmitter **30**. Communication reception at the receiving station is made possible by natural scatterers within the ionospheric layer, such as produced by natural discontinuities in the electron density within the ionosphere. These natural scatterers cause power leakages in the flow of the communications signal **32** through the ionospheric waveguide duct. These power leakages are shown as arrows **42**. By utilizing the antenna **41** along with a receiver **40**, it is thus possible to detect the power leakages due to scattering caused by natural scatterers within the ionosphere. This is shown diagrammatically as arrow **43** being received by antenna **41**. The antenna **41** could be of the Yagi type. The recetiver **40** may be of the double conversion superheterodyne type utilizing two local oscillators and two I_F stages. Thus, it is seen that once a communications signal is injected into the ionosphere and is then trapped in the waveguide duct of the ionopshere, a portion of this trapped signal can then be received after traveling over long distances. It is to be noted that this type of communications link does not depend on local minima or maxima in the ionopshere electron density profile. Furthermore, it is to be noted that this system does not rely upon the reflection of a signal off an ionized cloud and back down to a second location on the earth in order to obtain "one hop" point-to-point communications. Rather, the communications system presented here utilizes ionospherically trapped electromagnetic radiation in order to obtain point-to-point over the horizon communications.

Referring now to FIGS. 2, 3, 4, 5 and 6 for the description of a transmitter and antenna system shown as transmitter **11** and antenna **12** in FIG. 1. FIG. 2 illustrates the configuration of a Mills Cross antenna for generating the ionized cloud or artificial scatterer **14**. This antenna is of that type which is common to the radio astronomy field. A description of this type of antenna can be found in the book "Radio Astronomy," page 75, authored by J. L. Pawsey and R. M. Bracewell, published by Oxford at the Clarendon Press, under the date of 1955 in Oxford, England. An arrangement of this antenna is shown in a top plan view in FIG. 2. This Mills Cross antenna **50** is shown having two legs **51** and **52** and two legs **53** and **54**. The width of each of the legs is 12 meters and the length of each leg is 19 kilometers. The total antenna of this invention compriess 104,000 dipoles. A side elevational view of one of the dipoles is shown in FIG. 3 and has a radiating portion **58** which when mounted is parallel to the earth's surface and a vertical portion **59** which is used to mount each of these dipole antennas in the earth's surface. The horizontal radiating portion **58** is designed with a radiating surface equal to $\lambda/_2$ and the mounting portion **59** has a dimension of $\lambda/_4$. Each of the legs **51**, **52**, **53** and **54** have a total of 26,000 dipoles mounted four across to obtain the configuration shown in FIG. 2. Each of the legs has 6500 rows of four dipole antennas each.

The Mills Cross antenna **50** has the rows of dipoles comprising legs **53** and **54** connected in the same manner. For the purposes of explanation, a four dipole row in leg **53** will be described. This four dipole row is shown as **60** and has a transmitter **62** providing power to be radiated by each of the dipoles. A receiving antenna horn **61** is shown coupled to the transmitter **60** for the purposes of phasing the output radiation from each of the dipole antennas shown in **60**. The description of the phasing of the radiation of this antenna will be given in conjunction with an explanation of FIG. 6.

In order to show the connection of the dipole antennas of the legs **51** and **52**, a four row dipole antenna configuration **65** is singled out for purposes of description. Dipole antenna row **65** is shown coupled to a transmitter **67** which has an antenna horn **66** which is also used for the purposes of phasing the signal to be radiated by the dipole row **65**. Each of the transmitters of the Mills Cross antenna configuration provides a final stage power output of approximately one kilowatt peak power or 10 watts of average power. Since there are a total of 26,000 transmitters in this antenna configuration **50**, each providing one kilowatt, a total output power of approximately 26 megawatts peak power is obtained.

Referring now to FIG. 4 for a description of the transmiter **62**, a detector **70** is shown coupled to the antenna horn **61** for the purpose of receiving a phasing signal to be retransmitted. The signal to be retransmitted is applied to an R.F. amplifier **71** in order to amplify the detected signal to be retransmitted by the dipole configuration shown as **60**. The R.F. amplifier final stage is of the normal tetrode type of amplifier. R.F. amplifier **71** provides an amplified signal which is coupled through an impedance matching device **72** to feed the dipole antenna configuration **60**, as schematically shown in FIG. 4. The impedance matching device is utilized in order to couple the R.F. antenna to the dipole configuration **60**.

Referring now to FIG. 5, there is disclosed the transmitter **67**, having a detector **76**, R.F. amplifier **77**, and an impedance matching device **78** coupled between an antenna horn **66** and the dipole radiating configuration **65**. The apparatus of FIG. 5 is of the same type and operates similarly as does the apparatus of FIG. 4.

Referring now to FIG. 6, there is shown a scheme for phasing radiations from each of the dipole antennas of the Mills Cross antenna configuration **50**. Although it is possible to pre-set the phase of each of the transmitted signals which emanate from the dipole antennas by individually adjusting the phase of the signal provided by each of the transmitters of the antenna configuration **50**, a more effective technique for obtaining the proper phase relationship is shown in FIG. 6. This simplified technique is used to obtain the phase relationship to produce a cloud or artificial scatterer approximately 80 kilometers above the earth's surface. This technique utilizes two transmitters, **80** and **85**, which are slaved together by way of a ground link **87**. The transmtiters, **80** and **85**, simultaneously transmit a signal which emanates in the same phase relationship from each of these transmitters. By placing transmitter **80** perpendicular to and at a distance of approximately 80 kilometers from the legs **51** and **52** and transmitting this signal by way of a parabolic antenna configuration, and by simultaneously positioning transmitter **85** perpendicular to and at a distance of 80 kilometers from legs **53** and **54**, and transmitting a signal from a parabolic antenna **86**, it is possible to phase the signals radiated by the dipoles of the antenna **50** in order to produce the ionized cloud **14**. Thus, for example, by amplitude modulating a microwave frequency signal with a 50 megacycle per second signal, and by detecting this modulation with a detector, such as detector **70** or **76** of FIGS. 4 and 5, and then amplifying this 50 megacycle detected signal, the proper phase relationship for producing the ionized cloud is obtained. The proper phase is obtained since the phase of arrival of the 50 megacycle modulated microwave signal differs from point-to-point along the legs of the antenna configuration **50** in the same phase relationship that is required to recompose the field at 80 kilometers of height.

FIG. 7 is a pictorial representation of the earth surrounded by the ionospheric layers for the purpose of explaining the ionospheric waveguide ducts. For purposes of obtaining a reference from the earth's surface there is presented a pictorial diagram (not to be considered as drawn to scale) showing an ionospheric bottom layer **20** approximately 60 kilometers above the earth's surface, an F_1 layer substantially 150 kilometers above the earth's surface, an F_2 layer approximately 350 kilometers above the earth's surface, and outer ionosphere or exosphere about 2000 kilometers above the earth's surface. The ionosphere has the shape of a spherical shell and is concentric with the earth's surface.

Referring now to the portion of FIG. 7 numbered **35**, this stippled area represents the density of the electrons in the various regions of the ionosphere. For example, point *a* represents an electron density of approximately 10^3 electrons per cubic centimeter, which occurs at the ionospheric bottom. Point *b* represents the electron density at the F_1 layer, which is approximately equal to 10^5 electrons per cubic centimeter. Point *c* depicts the maximum electron density, which is presumed to exist at the F_2 layer of the ionosphere. At this point, an electron density of approximately 10^6 electrons per cubic centimeter is believed to exist. Point *d* on the tail end of the exponentially decaying region between points *c* and *d* represents an electron density of approximately 10^3 electrons per cubic centimeter which is considered to exist at the exposure.

Assume now that a transmitter, such as **11**, and an antenna **12**, which was previously disclosed with relation to FIGS. 1–6, generates an artificial scatterer **14** at approximately 80 kilometers above the earth's surface. Further, assume that a transmitter **30** and an antenna **31** directs a 20 megacycle communications signal in such a manner that the signal leaves the earth at an angle α of approximately 10° so that it is injected at an angle of α degrees into an ionospheric waveguide duct which lies between the bottom layer **20** and the F_2 layer **23**. The upper limit of the ionspheric waveguide duct, shown as the refractive layer **21** within the ionosphere, is a function of the frequency of the transmitted communications signal and the ionospheric conditions. The index of refraction of the ionosphere refractive layer is, among other things, a function of the local electron density of the ionospheric region and of the frequency of the transmitted communications signal. When the index of refraction approaches 0, refractive bending of a ray toward the earth's surface will take place. However, a trapped ray will not land on the earth's surface. For a 20 megacycle communications signal, a refractive layer **21** theorized at 130 kilometers, comprises the upper limit of the wave guidance duct. The lower limit of the ionospheric waveguide duct is a function of the angle α. In the situation required for trapping of the signal **32**, the lower limit is substantially bounded by the ionospheric bottom for an α which permits trapping. Therefore, for a 20 megacycle signal, the ionospheric waveguide duct will lie in the region between substantially 60 kilometers at its lower limit to 130 kilometers at its upper limit. For other frequencies, the waveguide duct will vary in accordance with the frequency of the communications signal.

Referring once again to the communications signal **32**, it can be seen that this signal **32** will be refracted from the artificial scatterer **14**, and be injected into the ionospheric duct, described previously. The signal after entering the duct will be trapped, due to the signal **32** being refracted periodically at points along the upper shell-like refractive layer **21**.

FIG. 8 is a schematic diagram of the communication system of this invention including a second artificial scatterer, which is placed in the ionospheric duct in order to extract a comunications signal trapped within the duct. A transmitter **30** and an antenna **31** is shown providing a communications signal **32** which is refracted by a scatterer **14** generated by a Mills Cross antenna **50**. This signal **32** is then periodically refracted by a refractive layer **21** and travels parallel to the earth's surface. A second Mills Cross type antenna emitting radiation, shown as arrowed lines **91**, places a second artificial scatterer **92** within the ionospheric duct which lies substantially between the ionospheric bottom **20** and the refractive layer **21**. This cloud **92** intercepts the communications signal **32** and reflects a major portion thereof. This is shown as arrowed lines **95** which are received by an antenna **96** and a receiver **97**. Although this particular embodiment is more costly than that which is shown in FIG. 1, due to the use of two artificial scatterers **14** and **92**, this embodiment will provide a communications system which will be operable over long distances at higher data rates. It is to be noted that this two scatter system is not of the "one-hop" reflective type. This system does not require that the artificial scatterers **14** and **92** be within line-of-sight of each other in order that there be over the horizon communications.

Referring now to FIG. 9, an alternate embodiment of an antenna is shown for producing an ionized cloud or scatterer, such as cloud **102**. The antenna **100** is of the ellipsoidic variety and is designed with a diameter of 40 kilometers to radiate and focus energy to produce the cloud **102**.

Although the preferred embodiment shows the use of separate antennas and transmitters to produce the cloud and to provide the communications signal, it is to be understood that a single station comprising a dual purpose antenna and transmitter could be used. Furthermore, it is to be understood that although a 20 megacycle communication signal is used in the preferred embodiment, other frequencies such as M.F., H.F., and V.H.F. frequencies of between approximately a few megacycles to 70 megacycles could be used. For example, recent tests have shown that communications between Massachusetts and Italy are possible utilizing this technique. Instead of generating an artificial scatterer, ionized meteor trails were utilized as scatterers to inject a 23 megacycle signal into an ionospheric waveguide duct. Receivers positioned in Italy detected a portion of the signal trapped within the duct. Additionally, this technique could be applied to satellite-borne receivers orbiting within the ionospheric waveguide duct or between ground stations and satellites. In addition, it is possible to use the trapped radiation technique of this invention in other regions of the atmosphere, such as in the troposphere. A tropospheric communications system would permit the propagation of frequencies in the V.H.F., U.H.F. and S.H.F. bands. Accordingly, it is desired that this invention not be limited except as defined by the appended claims.

We claim:

1. A communications system comprising:

means for generating and controlling an ionized cloud in the ionosphere, said means including first and second transmitters for simultaneously transmitting signals in the same phase relationship, ground link means for slaving said transmitters together, and antenna means for focusing on and accelerating ionospheric electrons with the electromagnetic radiation signals from said transmitters to produce ionizing collisions;

transmitting means for transmitting a communications signal directed at said ionized cloud, said cloud injecting said communications signal into and propagating said communications signal within an ionospheric signal trapping waveguide duct encircling the earth; and

means for receiving at least a portion of said communications signal trapped in the duct.

2. A system comprising:

means for transmitting a signal;

means for electromagnetically generating a scatterer within a given zone of the ionosphere, said scatterer injecting at least a portion of said signal into and causing said portion to propagate within an ionospheric signal trapping waveguide duct encircling the earth; and

means for receiving at least a portion of said signal trapped within said waveguide duct.

3. A system comprising:

means for transmitting a signal into a given zone of the atmosphere;

means for generating a scatterer in a given zone of the atmosphere, said scatterer causing said signal to be injected into and propagated within an atmospheric signal trapping duct to encircle the earth, and

means for detecting at least a portion of said signal trapped within said duct.

4. A system comprising:

means for providing a signal having a frequency below approximately 7 megacycles;

means for injecting at least a portion of said signal into a trapping zone of the ionosphere encircling the earth and defined by the ionospheric bottom layer and a refractive layer which is a function of the frequency of said signal and for causing said portion to propagate within said trapping zone around the earth; and

means for detecting at least a portion of said injected signal.

5. A communications system comprising:

means for providing a signal;

means for electromagnetically generating a scatterer to inject said signal into and to propagate said signal within a given signal trapping zone of the atmosphere encircling the earth; and

means for detecting at least a portion of said injected signal.

6. A communications system in accordance with claim **5** wherein said means for electromagnetically generating a scatterer includes an antenna for focusing on and accelerating ionospheric electrons with electromagnetic radiation signals to produce ionizing collisions.

7. A communications system in accordance with calim **6** wherein said antenna comprises a Mills Cross antenna having first and second perpendicular legs and includes means for phasing said antenna to produce said scatterer comprising first and second transmitters for simultaneously transmitting signals in the same phase relationship, each of said transmitters being perpendicular to and spaced apart from a different one of said legs, and ground link means for slaving said transmitters together.

8. A communications system comprising:

transmitting means for transmitting a communications signal;

transmitting means for electrromagnetically generating a scatterer in a given signal trapping zone in the ionosphere;

an antenna included in said scatterer generating means said scatterer being provided to inject said communications signal into and to propagate said communications signal within a given signal trapping zone of the ionosphere encircling the earth;

means for focusing on and acceleratnig ionospheric electrons with electromagnetic radiation signals to produce ionizing collisions;

means for phasing said antenna to produce said scatterer, said phasing means including first and second transmitters for simultaneously transmitting signals in the same phase relationship;

ground link means for slaving said transmitters together; and

means for receiving at least a portion of said communications signal which has been injected into and propagated within the given signal trapping zone.

9. A system comprising:

means for generating and controlling an ionized cloud including transmitter means for producing signals to accelerate ionospheric electrons and for stopping producing said signals to cause the removal of said cloud;

means for transmitting a signal directed at said cloud, said cloud injecting said signal into and propagating said signal within an ionospheric trapping waveguide duct encircling the earth; and

means for receiving at least a portion of said signal injected into said duct.

10. A system in accordance with claim **9** wherein said means for generating a cloud includes a near-field antenna producing a positive gradient electric field within said cloud at increasing distances from said antenna.

11. A communications system comprising:

means for providing a signal;

means for electromagnetically generating a scatterer within a region of the ionosphere below the ionospheric F_2 layer, said scatterer providing means for the injection and the porpagating said signal in a trapping zone of the ionosphere defined by the ionosphere bottom layer and a refractive layer which is a function of the frequency of said signal; and

means for receiving at least a portion of said trapped signal.

12. A communications system comprising:

means for transmitting a communications signal;

means for electromagnetically generating and controlling a scatterer within a given region of the ionosphere below the ionosphere F_2 layer, said scatterer being provided to inject said communication signal into and to propagate said communications signal within a trapping zone of the ionosphere defined by the ionospheric bottom layer and a refractive layer which is a function of the frequency of said communications signal;

said scatterer generating means including first and second transmiters for simultaneously transmitting signals in the same phase relationship, ground link means for slaving said transmitters together, and a near-field antenna for producing a positive gradient electric filed within the scatterer at increasing distances from the antenna; and

means for receiving at least a portion of the communications signal in said trapping zone.

13. A system in accordance with claim **11** including a second electromagnetically generated scatterer positioned within the zone of the ionosphere defined by the ionospheric bottom layer and said refractive layer, said scatterer providing means for extracting at least a portion of said signal trapped within said ionosphere.

14. A communications system comprising:

means for providing a signal having a frequency between a few megacycles to about 70 megacycles;

means for electromagnetically generating a scatterer within a given region of the ionosphere including transmitter means for producing signals to accelerate ionospheric electrons, said scatterer providing for the trapping of and the propagating of said signal within a given region of the ionosphere defined by the ionospheric bottom layer and a refractive layer which is a function of the frequency of said signal;

means for electromagnetically generating a second scatterer within a given region of the ionosphere to extract at least a portion of said signal including transmitter means for producing signals to accelerate ionospheric electrons; and

means for detecting at least a portion of said extracted signal.

15. A communications system comprising:

means for generating and controlling an ionized cloud in the ionosphere, said means including one transmitting means for simultaneously transmitting signals in a suitable phase relationship to achieve focusing of the radio frequency generated by the transmitting means, means for slaving the signals from said transmitting means and antenna means for focusing on and accelerating ionospheric electrons with the electromagnetic radiation signals from said transmitting means to produce ionizing collisions;

another transmitting means for transmitting a communications signal directed at said ionized cloud, said cloud injecting said communications signal into and propagating said communications signal within an ionospheric signal trapping waveguide duct encircling the earth; and

means for receiving at least a portion of said communications signal trapped in the duct.

16. A system comprising:

means for transmitting a signal;

means for electromagnetically generating a scatterer for injecting at least a portion of said signal into a trapping zone of the ionosphere encircling the earth, said zone defined by a lower boundary which is a function of the angle of injection of the signal into the zone and a upper refractive layer boundary which is a function of the frequency of said signal and for causing said portion to propagate within said trapping zone around the earth without any lower boundary reflections; and

means for receiving at least a portion of said signal trapped within said zone.

17. A system comprising:

means for transmitting a signal;

means for electromagnetically generating a scatterer for injecting at least a portion of said signal into a trapping zone of the ionosphere, said zone limited by an upper refractive layer which is a function of the frequency of said signal and for causing said portion to propagate within said trapping zone around the earth with reflections only off of the upper refractive layer; and

means for receiving at least a portion of said signal trapped within said zone.

18. A system comprising:

means for transmitting a signal;

a scatterer injecting at least a portion of said signal into a trapping zone of the ionosphere encircling the earth, said zone defined by a lower boundary which is a function of the angle of injection of the signal into the zone and an upper refractive layer boundary which is a function of the frequenncy of said signal and for causing said portion to propagate within said trapping zone around the earth without any lower boundary reflections; and

means for detecting at least a portion of said injected signal.

19. A system comprising:

means for transmitting a signal;

a scatter injecting at least a portion of said signal into a trapping zone of the ionosphere, said zone limited by an upper refractive layer which is a function of the frequency of said signal and causing said portion to propagate within said trapping zone around the earth with reflections only off of the upper refractive layer; and

means for detecting at least a portion of said injected signal.

20. A communications system comprising:

means for providing a signal;

means for electromagnetically generating a permanent and controllable scatterer to inject said signal into and to propagate said signal within a given signal trapping zone of the ionosphere encircling the earth, and

means for detecting at least a portion of said injected signal.

21. A method of communicating comprising the steps of:

electromagnetically generating a scatterer in a given zone of the atmosphere;

transmitting a signal into said scatterer in such manner that said signal is injected into and propagated within an atmospheric signal trapping duct encircling the earth; and

detecting at least a portion of said signal trapped within said duct.

22. A method of communicating comprising the steps of:

electromagnetically generating a scatterer within a given zone of the ionosphere;

transmitting a signal into said scatterer in such manner that at least a portion of said signal is injected into and propagated within an ionospheric signal trapping waveguide duct encircling the earth; and

receiving at last a portion of said signal trapped within said waveguide duct.

23. A method of communicating comprising the steps of:
- transmitting a communications signal;
- injecting at least a portion of said signal into a signal trapping zone of the atmosphere encircling the earth, said zone defined by a lower boundary which is a functon of the angle of injection of the signal into the zone and an upper shell-like refractive layer boundary which is a function of said signal, said signal being periodically refracted at points along the upper shell-like refractive layer without any lower boundary reflections as it is propagated approximately parallel to the earth's surface; and
- receiving at least a portion of the signal propagating within said trapping zone.

24. A method of communicting using trapped electromagnetic radiation comprising the steps of:
- transmitting a signal having a frequency below approximately 70 megacycles;
- injecting at least a portion of said signal into a trapping zone of the ionosphere encircling the earth and defined by the ionosphere bottom layer and a refractive layer which is a function of the frequency of said signal;
- propagating said signal within said trapping zone around the earth; and
- detecting at least a portion of said propagated signal.

25. A method of communicating using ionizing atmospheric collisions comprising the steps of:
- electromagnetically generating a scatterer in a given zone of the atmosphere;
- providing a communications signal which said scatterer injects into and propagates within the given signal trapping zone encircling the earth; and
- detecting at least a portion of said propagated signal.

26. A method in accordance with Claim 25 wherein the step of electromagnetically generating the scatterer includes:
- focusing electromagnetically radiation signals on atmospheric electrons within said given zone; and
- accelerating the electrons with the electromagnetic radiation signals to produce ionizing collisions.

27. A method in accordance with Claim 26 wherein the steps of focusing and accelerating include:
- simultaneously transmitting identically phased signals;
- slaving said phased signals together; and
- phasing an antenna to achieve the focusing and accelerating of the electrons to produce the ionizing collisions.

28. A method of communicating comprising tne steps of:
- generating an ionized cloud with electromagnetic radiation signals;
- controlling said cloud by said signals;
- transmitting a communication signal directed at said cloud such that said communication signal is injected into and propagated within an ionospheric signal trapping waveguide duct encircling the earth; and
- receiving at least a portion of said communication signal which has been injected into and propagated within said duct.

29. A method of communicating comprising the steps of:
- electromagnetically generating a scatterer within a region of the ionosphere below the ionospheric F_2 layer;
- transmitting a communication signal into said scatterer to inject into and propagate said signal within a signal trapping zone of the ionosphere defined by the ionospheric bottom layer and a refractive layer which is a function of the signal frequency; and
- receiving at least a portion of said trapped signal.

30. The method of claim 29 wherein said receiving step includes:
- electromagnetically generating a second scatterer positioned within the zone of the ionosphere defined by the ionospheric bottom layer and said refractive layer in order to provide means for extracting at least a portion of said trapped signal.

31. A method of communicating comprising the steps of:
- electromagnetically generating a scatterer within a given region of the ionosphere;
- transmitting a communications signal having a frequency between a few megacycles to about 70 megacycles into said scatter causing the signal to be trapped and propagated within the given region of the ionosphere defined by the ionospheric bottom layer and refractive layer which is a function of the frequency of the signal;
- electromagnetically generating a second scatterer within the given region of the ionosphere in order to permit extraction of at least a partion of said signal; and
- detecting at least a portion of said extracted signal.

32. A method of communicating comprising the steps of:
- electromagnetically generating an ionized cloud in the ionosphere;
- controlling said cloud by simultaneously transmitting signals in a suitable phase relationship to achieve focusing of the radio frequency generated, slaving the transmitted signals together and focusing on and accelerating ionospheric electrons with the electromagnetic radiation signals to produce ionizing collisions;
- transmitting a communications signal directed at said ionized cloud to inject into and propagate said communications signal within an ionospheric signal trapping waveguide duct encircling the earth; and
- receiving at least a portion of said communications signal trapped in the duct.

33. A method of communicating comprising the steps of:
- electromagnetically generating a scatterer within a given region of the ionosphere;
- transmitting a communications signal into said scatterer to inject at least a portion of said signal into and propagate it within a trapping zone of the ionosphere defined by a lower boundary which is a function of the angle of injection of the signal into the zone and an upper refractive layer boundary which is a function of the frequency of said signal, the propagation occurring without any lower boundary reflections; and
- receiving at least a portion of said signal trapped within said zone.

34. A method of communicating comprising the steps of:
- electromagnetically generating a scatterer within a given region of the ionosphere;
- transmitting a communications signals into said scatterer to inject at least a portion of said signal into and propagate it within a trapping zone of the ionosphere limited by an upper refractive layer which is a function of the frequency of said signal, the propagation occurring with reflections only off of the upper refractive layer; and
- receiving at least a portion of said signal trapped within said zone.

35. A method of communicating comprising the steps of:
- electromagnetically generating a permanent and controllable scatterer in a given zone of the atmosphere;
- directing a communications signal into said scatterer to inject said signal into and to propagate said signal within the given zone of the atmosphere; and
- detecting at least a portion of said injected signal.

36. A communications system as set forth in claim **15** wherein said antenna is employed in a near-field arrangement.

37. A communications system as set forth in claim **36** where:

said antenna comprising a Mills Cross antenna having first and second sets of perpendicular legs; and

said one transmitting means comprises first and second transmitters for simultaneously transmitting signals in the same phase relationship, each of said transmitters being perpendicular to and spaced apart from a different one of said legs.

38. A communications system as set forth in claim **37** wherein:

each of said antenna legs has a width of approximately twelve meters and a length of approximately nineteen kilometers;

said antenna has a horizontal radiating surface equal to one half wavelength and a mounting portion of one quarter wavelength; and

said first and second transmitters each being spared approximately 80 kilometers from the corresponding legs of said antenna and each having a parabolic transmitting antenna.

39. A communications system as set forth in claim **38** wherein:

said ionized cloud is located approximately 80 kilometers above the earth's surface, has a mean width of approximately 15 meters, a length of approximately 60 meters and tapers in a cone-shaped fashion from its widest portion to a point at its greatest distance from the earth's surface.

40. A communicating system as set forth in claim **15** wherein:

said another transmitting means transmits a communications signal having a frequency between a few megacycles to about 70 megacycles; and

said transmitting means including a transmitter and an antenna, said antenna being of the directional type.

41. A communications system as set forth in claim **40** wherein:

said antenna is a rhombic antenna.

42. A communications system as set forth in claim **40** wherein:

said antenna is a yagi antenna.

43. A communications system as set forth in claim **40** wherein:

said directional antenna is positioned so that the communications signal leaves the earth at an angle α of approximately 10° and the angle of injection into said duct is approximatetly α.

44. A communications system as set forth in claim **15** wherein:

said receiving means includes a receiver, said receiver being a double conversion superheterodyne receiver having two oscillators and two IF stages and a receiving antenna.

45. A communications system as set forth in claim **44** wherein:

said receiving antenna being a yagi antenna.

46. A communications system comprising:

means for generating and controlling an ionized cloud in the ionosphere, said means including one transmitting means for simultaneously transmitting signals in a suitable phase relationship to achieve focusing of the radio frequency generated by the transmitting means, means for slaving the signals from said transmitting means and antenna means for focusing on and accelerating ionospheric electrons with the electromagnetic radiation signals from said transmitting means to produce ionizing collisions;

another transmitting means for transmitting a communications signal directed at said ionized cloud, said cloud injecting said communications signal into and propagating said communications signal within an ionospheric signal trapping waveguide duct encircling the earth;

means for generating and controlling a second ionized cloud within said duct to extract at least a portion of said signal including means for producing signals to accelerate ionospheric electrons; and

means for detecting at least a portion of the signal intercepted by said second cloud.

47. A communications system comprising:

means for generating and controlling an ionized cloud within a given zone of the ionosphere, said means including,

one transmitting means comprising first and second transmitters for simultaneously transmitting electromagnetic radiation signals in the same phase relationship to achieve focusing of the radio frequency generated by the transmitting means,

means for slaving the signals from said transmitters,

antenna means for focusing on and accelerating ionospheric electrons with the signals from said transmitting means to produce ionizing collisions, said means comprising an antenna employed in a near-field arrangement and being a Mills Cross antenna having first and second sets of perpendicular legs, each of said transmitters being perpendicular and spaced apart from a different one of said sets of legs;

another transmitting means including a transmitter and a directional antenna for transmitting a communications signal having a frequency between a few megacycles to about 70 megacycles and directed at said ionized cloud, said cloud injecting at least a portion of said communications signal into and propagating within an ionospheric signal trapping zone encircling tne earth, said zone defined by a lower boundary which is a function of the angle of injection of the signal into the zone and an upper shell-like refractive layer boundary which is a function of the frequency of said communications signal, said signal being periodically refracted at points along the upper shell-like refractive layer without any lower boundary reflections as it is propagated approximately parallel to the earths surface;

means for generating and controlling a second ionized cloud within said zone to extract at least a portion of said communications signal including means for producing signals to accelerate ionospheric electrons; and

means for receiving at least a portion of said communications signal trapped witnin said zone.

48. A communications system as set forth in claim **47** wherein:

each of said antenna legs has a width of approximately 12 meters and a length of approximately 19 kilometers;

said antenna has a horizontal radiating surface equal to one half wavelength and a mounting portion of one quarter wavelength; and

said first and second transmitters each being spaced approximately 80 kilometers from the corresponding legs of said antenna and each having a parabolic transmitting antenna.

49. A communications system as set forth in claim **48** wherein:

said ionized cloud is located approximately 80 kilometers above the earths surface, has a mean width of approximately 15 meters, a length of approximately 60 meters and tapers in a cone-shaped fashion from its widest portion to a point at its greatest distance from the earth's surface.

50. A communications system as set forth in claim **47** wherein:

said directional antenna is positioned so that the communications signal leaves the earth at an angle α of approximately 10° and the angle of injection into said zone is approximately α.

51. A communications system as set forth in claim **47** wherein:

said receivng means includes a receiver, said receiver being a double conversion superheterodyne receiver having two oscillators and two IF stages and a receiving antenna.

52. A communications system as set forth in claim **51** wherein:

said receiving antenna being a yagi antenna.

53. A communications system as set forth in claim **47** wherein:

said second cloud generating and controlling means includes,

one transmitting means comprising first and second transmitters for simultaneously transmitting electromagnetic radiation signals in the same phase relationship to achieve focusing of the radio frequency generated by the transmitting means,

means for slaving the signals from said transmitters;

antenna means for focusing on and accelerating ionospheric electrons with the signals from said transmitting means to produce ionizing collisions, said means comprising an antenna employed in a near-field arrangement and being a Mills Cross antenna having first and second sets of perpendicular legs, each of said transmitters being perpendicular and spaced apart from a different one of said sets of legs.

54. A communications system as set fortn in claim **49** wherein:

said Mills Cross antennas each operate at a frequency of approximately 50 megacycles and provide approximately 26 negawatts of peak power and 260 kilowatts of average power.

55. A communications system as set forth in claim **47** wherein:

both said cloud generating and controlling means as well as said communications signal transmitting and receiving means are located near the earths surface.

56. A communications system as set forth in claim **47** wherein:

the lower boundary of said zone is substantially bounded by the ionospheric bottom layer which is approximately 60 kilometers above the earths surface and the upper boundary is substantially bounded by the ionospheric F_2 layer, which is approximately 350 kilometers above the earths surface.

57. A communications system as set forth in claim **36** wherein:

said antenna is an ellipsoidic antenna having a diameter of approximately 40 kilometers.

FIG. 2

CREATION OF ARTIFICIAL IONIZATION CLOUDS ABOVE THE EARTH

DESCRIPTION

1. Technical Field

The present invention relates to a method for establishing a patch or cloud of artificial ionization above the earth and more particularly, relates to a method of forming a cloud of artificial ionization by heating naturally occurring plasma with electromagnetic energy which is transmitted from the Earth's surface at a variable, increasing frequency.

2. Background Act

Certain communication and radar systems operate by "bouncing" transmitted and/or reflected signals off of naturally-occurring layers of ionization in the ionosphere. One known system using this technique is "over-the-horizon" (OTH) radar. By bouncing or reflecting the signals off an ionized layer, the signals can actually travel "over-the-horizon", thereby substantially increasing the range of the system.

However, while present OTH systems are capable of detecting objects at long range (e.g. strategic threats), they are not well suited for detecting "close-in" objects (e.g. missiles at 1000 kilometers or less). One problem lies in the fact that as the beam angle of the radar is increased from the horizontal, the frequency of the beam must be lowered in order to achieve refraction at a more nearly normal incidence. As this frequency is lowered, the antenna system gain is reduced and the radar cross section decreases for small close-in object. These effects act to set a minimum range for the OTH system.

Another major problem with present OTH systems is related to the low radar cross section of small targets at typical OTH operating frequencies. These objects having small cross-sections produce a weak return signal even when the object is within the range of the OTH radar since the OTH system is normally designed for objects having much larger cross-sections, e.g. large aircraft.

A still further problem encountered by present OTH radar is directly related to the unstable conditions in the ionosphere which widely vary depending on seasonal, diurnal, and/or sunspot cycles. Accordingly, the operating frequency of present OTH radar systems has to be constantly adjusted to allow for the varying ionospheric conditions which may vary so much at times that the OTH system is rendered inoperable.

Several techniques have been proposed to overcome some of the shortfalls of present OTH radar systems. One known technique is disclosed in U.S. Pat. No. 3,445,844 wherein a cloud of artificial ionization is formed above the earth to serve as a layer for redirecting communication signals. The cloud is formed by "breakdown", i.e. creation of a high level flux of free electrons (i.e. plasma) at a desired altitude by focusing electromagnetic energy thereon to heat a localized region or area. The electromagnetic energy heats and accelerate the electrons in the resident plasma to a degree such that their kinetic energy reaches the level required for the occurrence of ionizing collisions. Scattering from a cloud so formed takes place due to the discontinuity between this zone of enhanced ionization and the surrounding medium.

A cloud formed in accordance with the method disclosed in U.S. Pat. No. 3,445,844 will provide a good reflection layer for OTH radar and like systems. However, when a cloud is formed by breakdown as in the mentioned patent, the plasma frequency of the cloud quickly adjusts to the hating frequency and breakdown is initiated over the entire area of the cloud. By initiating and forming the cloud with radiation having the same high frequency as that required for continued maintenance of the cloud once formed, a substantial amount of power is required, much of which is reflected or passes through the cloud while it is being formed and, accordingly, is wasted.

BRIEF DESCRIPTION OF THE DRAWINGS

The actual construction, operation, and apparent advantages of this invention will be better understood by referring to the drawings in which like numerals identify like parts and in which:

FIG. 1 is a simplified schematical view of a system for forming a cloud of artificial ionization above the earth for bouncing signals over-the-horizon in accordance with the present invention; and

FIG. 2 is a schematic illustration of a cross-beam radiation transmission system for forming a cloud of artificial ionization in accordance with the present invention.

DISCLOSURE OF THE INVENTION

The present invention provides a method for forming a patch or cloud of artificial ionization at an altitude above the earth wherein no substantial amounts of power are wasted in forming and maintaining the cloud.

More specifically, the present invention provides a method wherein variable frequency heating is used to form a cloud of artificial ionization. This is accomplished by initially heating the resident plasma at the selected altitude by transmitting electromagnetic radiation from the earth at an initial frequency which is approximately the same frequency as the ambient plasma frequency. This radiation, being of the same frequency as the plasma, will be efficiently absorbed with relatively little being reflected from or passed through the ambient plasma. The radiation heats the plasma and accelerates the free electrons in the plasma thereby increasing the plasma frequency.

The frequency of the plasma is monitored by radar or the like and, as it increases, the frequency of the radiation being transmitted also increases, preferably in a manner where the radiation frequency continues to substantially match the increasing plasma frequency. The radiation frequency is continuously increased until the final maintenance frequency is attained, at which time, the transmission of electromagnetic radiation is continued at the final frequency to maintain the integrity of the cloud. The final plasma frequency (i.e. maintenance frequency) is selected so that it is always greater than the frequency of any signals (e.g. communications, radar) that are expected to be "bounced" off the cloud once the cloud is used for its intended purpose.

To further conserve power and to reduce the power required for carrying out this invention, the initial radiation is weakly focused so that only the center area of the plasma within the cloud are will undergo initial heating. The focus of the radiation is contracted as the radiation frequency is increased until the entire cloud are is heated by the radiation. The radiation can be transmitted by a single antenna system or by two spaced antenna systems positioned so that their beams intersect at said altitude to thereby form the cloud.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

Referring more particularly to the drawings, FIG. **1** is a illustration of how the present invention is utilized with an over-the-horizon (OTH) radar system. A cloud **10** of artificial ionization is formed at an altitude above the surface of the earth **11** by transmitting electromagnetic energy **12** from an antenna system **13**. An OTH radar system **14** transmits and receives signals **15** that are reflected off cloud **10** to detect a target **16** that is "over-the-horizon" as will be understood in the art.

In accordance with the present invention, cloud **10** is formed by variable frequency heating. The degree of ionization in the ionosphere depends on the electron temperature of the average energy of the free electrons; i.e. plasma, at a particularly altitude. The electron energy can be increased by absorption of incident electromagnetic radiation. This, in turn, increases the degree of ionization (i.e. number of free electrons and ions per unit volume). The higher the electron density of an ionized layer, the higher the frequency of radio or radar waves that can be reflected from that layer in communications or radar applications.

To raise the electron temperature efficiently, it is necessary to irradiate the ionosphere at or near the frequency of the plasma that is naturally present at the altitude of interest. "Plasma frequency" is defined roughly as the highest frequency that will be reflected from a particular altitude in the ionosphere and this frequency will increase as the electron density increases. However, if the frequency of the incident radiation used to heat the plasma is much higher or lower than the plasma frequency a large portion of the radiation will not be absorbed but will be reflected or passed through the heating zone and will be wasted.

In the present method, a target altitude at which cloud **10** is to be formed is selected and the frequency of the natural plasma is determined by tracking radar or the like. Heating is begun by transmitting electromagnetic radiation **12** from antenna system **13** at substantially the same frequency as that of the plasma resident at the target altitude. Radiation **12** is absorbed efficiently by the plasma at the target altitude which increase the electron density thereof which, in turn, increases the frequency of the plasma frequency. As the plasma frequency increases, the frequency of radiation **12** is increased to approximately match the increasing plasma frequency. By constantly tracking the increasing plasma frequency and adjusting the frequency of the heating radiation accordingly, almost all, if not all, of the power being used to heat the ionospheric electrons is absorbed efficiently into the plasma over the entire heating cycle. In this way, the electron density (degree of ionization) can be raised to the desired level without any substantial waste of power which otherwise would be considerable.

In the present method, the initial heating is carried out with the radiation **13** being broadly focused so that the central area within cloud **10** is being heated. As the plasma frequency within the smaller area is increased, the focused area of radiation **13** is contracted until the entire final area of cloud **10** is being heated by the radiation **13**. This minimizes the initial heating power requirements and results in a further substantial reduction in the overall power requirements for forming cloud **10**.

The antenna system **13** required to transmit radiation **12** in the present invention may be of any known construction having high direct inability capabilities; for example, a phased array, beam spread angle (O) type see U.S. Pat. No. 3,445,844 and the "The MST RADAR at Poker Flat, Ak.," Radio Science, Vol. 15, No. 2, March-April, 1980; pps. 213–223, both of which are incorporated herein by reference. A phased array antenna generating a steerable focused beam can be assembled at a single site or two phased array antenna systems **20, 21** (FIG. **2**) may be spaced from each of other to generate two coherent beams **23, 24** of radiation that cross each other at the selected altitude to form cloud **10***a*.

The key beam geometric parameters of a two antenna system are shown in FIG. **2**. The beam of radiation from each antenna is assumed to diverge in the azimuthal plane (b) and to be collimated in the elevational plane (a). This assumption is appropriate for a backscatter cloud that must be inclined about 45 degrees from the horizontal. For forward scattering, with cloud **10***a* either directly overhead or downrange from an antenna, the beam will diverge in both planes and "b" would be used for both antenna. The following relationships can be used to calculate the various parameters of the system of FIG. **2**:

$$a \cong \sqrt{2\lambda_p R} \qquad (1)$$

wherein:

a=length of side of antenna array in elevational plane.

λp=Wavelength of Radiation Frequency

R=Actual distance from array to cloud **10***a*.

$$b \cong \frac{\lambda_p R}{W} \qquad (2)$$

wherein:

b=length of side of antenna array in azimuthal plane

W=Width of cloud **10***a*

$$S = \frac{Ra}{D} \qquad (3)$$

S=distance between arrays.

D=Depth of cloud **10***a*.

While the size and characteristics of a particular cloud **10** will vary depending on its application and actual conditions under which it is formed, the following example will serve to better illustrate the present invention. A cloud **10** (FIG. **1**) is to formed at an altitude of 90 kilometers (km) and is to have a final area of 1 square km or larger with a thickness of from 3 to 10 meters. The resident plasma density at 90 km is typically on the order of 10^6/cubic cm. A square, phased array antenna system **13** of 100 meters on a side, beams electromagnetic radiation 12 (i.e. power) at an initial or starting frequency to initiate heating of the resident plasma. Antenna **13** is focused so that only the plasma at the center of cloud **10** will initially be heated, thereby requiring substantially less power than if the entire 1 square km area of the cloud was originally heated.

Since the plasma frequency of the ambient plasma is approximately 9 megahertz (MH_z), about 70 MW of power will be required. As the plasma heats, the frequency thereof increased and is tracked by groundbased radar. As the frequency of the plasma increases, the frequency of radiation **12** is increased accordingly until a frequency of 15 MHz is reached. The power requirement at this point will have dropped to approximately 27 MW.

At this point, the focus of the antenna is contracted to cover a greater, if not all, of the area of cloud **10**, and radiation **12** (i.e. heating) is now applied over the entire area. Due to the increased heating area, the power requirement is temporarily increased to approximately 33 MW but will quickly decrease as the radiation frequency continues to increase until the final maintenance frequency of 300 MH_z is reached. The power requirement for the final maintenance frequency is approximately 7 MW and final electron or plasma density will be about 10^9/cubic cm.

The integrity of cloud **10** will be maintained as long as radiation **12** is transmitted thereto at the final maintenance frequency. The final maintenance frequency for any particular cloud is interrelated to the frequency of the radar or other communication signal which is to be bounced off that cloud. That is, it is generally preferably to have the plasma frequency of the cloud substantially higher than the radar frequency. This will ensure a high degree of reflection for the radar. Also, irregularities in the plasma density may form in the cloud. These will commonly be spaced about one heater wavelength apart. This spacing should be relatively small compared to a radar wavelength to avoid excessive scattering of the radar signal in undesirable directions.

What is claimed is:

1. A method of forming a cloud of artificial ionization at an altitude above the earth, said method comprising:

initiating heating of the resident plasma at said altitude by transmitting electromagnetic radiation from the earth to said altitude at an initial frequency which is approximately the same as the original frequency of said resident plasma; and

increasing said frequency of said electromagnetic radiation as said frequency of said resident plasma increases, until a final maintenance frequency is attained, said maintenance frequency being t or above the plasma frequency necessary to provide a plasma having an electron density capable of reflecting communication or like signals which come into contact with said plasma.

2. The method of claim **1** including:

defocusing said electromagnetic radiation so only the center area of said cloud is initially heated; and

contracting the focus of said electromagnetic radiation as the frequency of said radiation is adjusted until the entire area of said cloud is heated.

3. The method of claim **1** wherein said electromagnetic radiation is transmitted by a single antenna system.

4. The method of claim **1** wherein said electromagnetic radiation is transmitted by two antenna systems, each spaced from the other, and inclined whereby the beams of said electromagnetic radiation transmitted from said systems will intersect each other at said altitude.

5. A variable frequency heating method for forming a cloud of artificial ionization at an altitude above the earth, said method comprising:

transmitting electromagnetic radiation form the earth to said altitude at an initial frequency which is approximately the same as the original frequency of the plasma naturally present at said altitude;

focusing said electromagnetic radiation to heat said plasma to thereby accelerate the free electrons therein thereby increasing the frequency of said plasma;

monitoring the frequency of said plasma as it increases;

increasing the frequency of said electromagnetic radiation as said frequency of said plasma increases;

continuing to increase said frequency of said electromagnetic radiation until a final desired maintenance frequency is attained; said final desired frequency being at or above the plasma frequency necessary to provide a plasma having an electron density capable of reflecting communication signals or the like which come into contact with said plasma;

and continuing to transmit said electromagnetic radiation at said final frequency to maintain the integrity of said cloud.

6. The method of claim **5** wherein said final frequency is greater than the frequency of any communication and/or radar signals expected to be reflected by said cloud.

7. The method of claim **6** wherein said electromagnetic radiation is initially focused whereby only the center area of said plasma is initially heated.

8. The method of claim **7** including:

contracting the focus of said electromagnetic radiation as the said frequency of said radiation is increased whereby the entire area of said cloud is heated.

9. The method of claim **8** wherein said frequency of said electromagnetic radiation is increased to approximately match said increasing frequency of said plasma.

10. The method of claim **9** wherein said electromagnetic radiation is transmitted by a single antenna system.

11. The method of claim **9** wherein said electromagnetic radiation is transmitted by two antenna systems, each spaced from the other, and inclined whereby the beams of said electromagnetic radiation transmitted from said systems will intersect each other at said altitude.

[57] **ABSTRACT**

This invention relates to generation of a Artificial Ionospheric Mirror (AIM), or a plasma layer in the atmosphere. The AIM is used like the ionosphere to reflect RF energy over great distances. A tiltable AIM is created by a heater antenna controlled in phase and frequency. The heater antenna phase shift scans a beam to paint a plasma layer. Frequency is changed to refocus at continually higher altitudes to tilt the plasma layer.

ARTIFICIAL IONOSPHERIC MIRROR COMPOSED OF A PLASMA LAYER WHICH CAN BE TILTED

BACKGROUND OF THE INVENTION

1. Field of the Invention

This invention relates to generation of a Artificial Ionospheric Mirror (AIM), or a plasma layer in the atmosphere. The AIM is used like the ionosphere to reflect RF energy over great distances.

2. Description of the Related Art

In the past, the technique of using the ionosphere as a mirror to reflect radio waves, or RF energy, has given Ham Radio operators the ability to send transmissions over long distances. This technique has also provided radar systems the ability to look "over the horizon." Variations and fluctuations in the ionosphere, however, can render the effectiveness of such communications uncertain. Thus, the desirability of creating controllable plasma layers in the atmosphere for communications purposes has been recognized. See, for example, U.S. Pat. No. 4,686,605 issued to Eastlund and U.S. Pat. No. 4,712,155 issued to Eastlund et al.

Previous experiments directed toward creating plasma layers for communications have suffered from the inability to control the inclination of the plasma layer so that signals could be transmitted and received from various ranges. In other words, while one could create a plasma layer in the atmosphere at a lower altitude than the ionosphere, point to point communications would be limited in range based on the reflection angles of the transmitted and reflected signals.

SUMMARY AND OBJECTS OF THE INVENTION

In view of the limitations of the related art it is an object of this invention to generate a plasma layer that could be angled or tilted with respect to the horizon in order to affect signal transmission range.

The present invention provides a system and method for generating a plasma layer at controlled altitudes and inclinations that acts as an artificial ionospheric mirror (AIM) to reflect RF signals. The AIM increases the range and predictability with which RF energy may be reflected off the AIM for communications purposes. More specifically, a tiltable AIM is created by a heater antenna controlled in phase and frequency. The heater antenna phase shift scans a beam to paint a plasma layer. The heater antenna continually refocuses at a higher altitudes by frequency shifting to tilt the plasma layer.

BRIEF DESCRIPTION OF THE DRAWINGS

Further details of the present invention are explained with the help of the attached drawings in which:

FIG. **1** shows creation of an AIM by a heater antenna and use of the AIM for tracking aircraft and reflecting radio waves.

FIG. 2 shows a typical heater array.

FIG. 3 shows the spacial relationship for a heater array used in defining heater array focusing.

FIG. **4** is a graph showing that power is at its upper bound at the antenna focal point.

FIG. 5 shows generation of plasma by a heater array.

FIG. 6 illustrates generation of a plasma layer by scanning a heater antenna.

FIG. 7 illustrates generation of a tilted plasma layer by scanning and refocusing a heater antenna.

FIG. **8** shows generation of a plasma layer using a heater antenna to scan with a line rather than a point.

FIG. **9** shows the phase corrections to move the antenna focal point from **60** Km to **61** Km.

FIG. **10** shows the frequency corrections to move the antenna focal point from **60** Km to **61** Km.

FIG. **11** is a plot of altitude v. distance location of plasma without frequency chirping.

FIG. **12** is a plot of altitude v. distance location of plasma with frequency chirping.

FIG. **13** shows the power density change after refocusing using frequency chirping .

FIG. **14** graphs the free electron density v. altitude for an unfocused array.

FIG. **15** shows an antenna power pattern without grating lobes.

FIG. **16** shows an antenna power pattern with grating lobes.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

FIG. **1** illustrates the creation and use of An Artificial Ionospheric Mirror (AIM) for tracking aircraft and reflecting radio waves. A heater antenna **1** radiates power causing avalanche ionization or breakdown releasing free electrons in the atmosphere to generate the AIM **2**. The heater antenna **1** is an array which can be used to focus energy at varying altitudes and elevations to tilt the AIM **2** using phase and frequency control. The AIM **2** simulates the ionosphere **3** which is also used to detect "over the horizon targets" **5**. In addition, the AIM **2** can reflect radio signals transmitted from a transmitter **6** to a receiver **7** over long distances.

A typical heater antenna is shown in FIG. **2**. It consists of an array of multiple active radiating elements **10** having their individual phase and frequency controlled from a control module **12**. The radiating element **10** is used here to represent all possible antennas, including, but not limited to, dipoles, slots, small or large horns, log-periodic antennas, large parabolic reflectors, etc.

FIG. **3** shows the spatial relationship for a focused heater array. To have the electric fields from all of the array elements focus, or arrive in phase at a distance R_o in the near field of the array, it is necessary to correct the phase of each element to compensate for the phase delay difference from the center element due to the additional phase path W_{ij}. If R_o is much larger than the maximum D_{ij} in FIG. **3**, then the phase delay can be approximated in wavelength to be:

$$W_{ij}=(D_{ij})^2/(4*R*g) \quad (1)$$

where g is the wavelength of the heater frequency. Equation 1 is referred to as the quadratic phase error. If this error is less than g/8 when the element (i,j) is on the outer edge of the array, then the distance R_o is said to be in the far field of the array.

In order to focus the array at R_o, it is necessary to have several wavelengths of phase error from the outer elements of the array. That is, the term "focus" is used in this context to mean that the electric field from the array is concentrated in a desired spatial region.

FIG. **4** shows the degree of focusing that can be accomplished. This is a vertical pattern of an array whose elements have been phase shifted to focus at 60 Km. The array has 400 elements with a total width and length of 2000 g. The peak of the pattern is determined by the $1/R_o^2$ dependence.

The AIM ionization layer is created by using this focused power to ionize an area in the atmosphere, as shown in FIG. 5. The microwave breakdown of air occurs where free electrons gain enough energy from an electric field to generate additional free electrons until no more can be generated, thereby resulting in avalanche ionization, or breakdown. This causes the generation of a plasma layer **21**. For example, a pulse of power from the heater begins to propagate in the z direction shown in FIG. **5**. As the field propagates, more free electrons are generated. A breakdown point descends vertically from the focal point of the propagating field giving thickness to the ionized layer, or plasma layer, until all ionization stabilizes. This "clamping" creates a thin vertical plasma layer.

Simulation results show that when an array **20** is focused at a point **22**, electric field power peaks at the focal point. Simulation results shows that given a focused microwave source avalanche ionization, or breakdown will occur at a power level 3–10 dB below the focal point power level.

To create an AIM, the heater array is focused at a desired altitude to maximize power at a point and thereby generate plasma. The heater antenna then "scans" the phase of each array element to move the focal point.

FIG. **6** illustrates creation of a noninclined AIM layer. The heater array **30** is first focused at point **31**. The heater array scans horizontally by phase shifting to a point **32** creating an avalanche ionization line **33**. Next, the heater array scans from a point **34** to a point **35** creating another avalanche ionization line **36**. The heater array continues this process to create an ionization plane or AIM layer.

In order to form an inclined AIM cloud, each new ionization line must occur at a slightly higher altitude. By altering the phase or frequency of the array elements, the focal point can be moved up in altitude, as described below.

FIG. **7** illustrates creation of an inclined AIM. The heater array **40** is first focused at point **41**. The heater array scans along the x direction to point **42** to generate avalanche ionization along line **43**. Next, as in creation of a non-inclined AIM, the heater array scans along the x and y directions directly below point **44**. The heater array **40** alters either phase or frequency to refocus to a higher altitude in the z direction to the point **44**. The heater array then scans along the x axis to point **45** to create the avalanche ionization line **46**. The heater array continues this process to create a tilted ionization plane or tilted AIM layer.

FIG. **8** shows that the preferred method of generating a plasma layer uses a heater antenna to scan with a line rather than a point. Scanning using a line is preferred since an AIM can be created in the atmosphere in less time. To create lines of ionization rather than points, a rectangular array **50** is used. In the array **50**, radiating elements are focused only along the plane of the long dimension of the rectangular array, creating a line of ionization **53**. The array is then scanned along the x-y axis and in altitude along the z axis to create another ionization line **55**. More ionization lines are similarly generated to form a tilted AIM layer.

In order to create a tilted AIM it is necessary to refocus the heater array at successively higher altitudes. Moving the focal point by changing the phase of each element of the heater in a very precise manner is not practical. Moving the focal point away from the initial location requires changing the phase on each element. The phase change required is near the rms tolerance level, typically 1 degree. FIG. **9** shows the required phase corrections to move the focal point from 60 Km to 61 km. Elements **5**, **10**, **15**, and **20** have distances 5d, 10d, 15d, and 20d, respectively from the center of the antenna, where d=25 meters It is clear from FIG. **9** that it is impractical to alter numerous antenna element phases to move the focal point to create tilted patches for AIM applications. 2000 elements may be required here to generate enough power to ionize the atmosphere.

The second method of refocusing is accomplished by first setting the phases of all elements for the initial focal point and then moving the focal point by changing the frequency rather than the phase. This frequency chirping method is less precise, but easier for hardware implementation because precise phases for 2000 elements need not be changed. FIG. **9** shows the required phase corrections to move the focal point from 60 Km to 61 Km. FIG. **10** shows that the focal point can be moved 100 meters by increasing the frequency approximately 1 Mhz. The resulting focal point power levels are not completely optimized, but simulation shows that there is less than a 0.1 db difference between the frequency shifted peaks and those obtained by phasing.

Tilting the AIM using frequency chirping is practical to achieve in a real system. FIG. **11** shows the plasma layer location with no frequency chirping. FIG. **12** shows the plasma location of the same heater creating a tilted AIM by increasing frequency from 550 MHz to 559.375 MHz while scanning horizontally. The result is a smooth patch with a 45 degree inclination.

While it is true that frequency chirping does not achieve the same power as phase focusing at the higher altitude, the difference for small frequency chirps is negligible. FIG. **13** shows actual power density data generated by a 300 MHz heater focused at 70 km with the frequency chirped to 308 MHz.

In the far field region, power meets its upper bound without focusing. For a far field or unfocused array, there is no way to raise the ionization altitude or create a tilted AIM. Ionization takes place at a point where there is enough power to initiate breakdown and where there is low enough neutral density (i.e. pressure). This usually occurs between 40 and 50 km altitude as shown in FIG. **14**. Consequently, a near field focused antenna is required to create a controlled AIM.

The focused pattern is a picture of constructive and destructive interference of the fields from the elements of the array. Other interference positions, or grating lobes, outside the focal point occur when some of the array elements add up in phase. The power of grating lobes can be kept below that of the main lobe, or focal point, by having a large number of elements in the array and spreading them out over the array aperture. This is called thinning the array. For square arrays having 400 elements or more grating lobes can be kept down by 20 db or more from the focal point.

The degree of focusing depends on the ratio of focal range to aperture size. The half power width from peak "V" can be approximated as:

$$V=2*g*(R_o/L)^2 \quad (2)$$

where L is the length of the array which is assumed square for equation 2. The power gradient at the half power point "grad(P)" can be approximated as:

$$grad(P)=10/V(db/meter) \qquad (3)$$

For an AIM it is desirable that the power gradient be high because this directly determines the gradient of the electron density of the generated ionized cloud. The electron density must be high to avoid RF losses caused by absorption. Hence V be small, preferably less than 2 Km. A heater frequency of 300 MHz and a focal distance of 70 Km would project an aperture size greater than 2 Km. Note in equation 2 that array size scales with the square root of frequency.

Since a near field antenna is required, the near field of the heater antenna may be required to extend to reach distant points. This is accomplished by increasing the array size. It may not be economically feasible to fill this entire aperture with elements, hence a thinned array is utilized.

If a thinned array had its elements uniformly distributed, there would be many grating lobes in the radiation pattern of the array. These grating lobes can be eliminated by randomly spacing elements. However, random spacing puts power from the grating lobes into the average side lobe level. If no new elements are introduced when the aperture is increased, then the peak power of the main lobe remains constant and the main lobe receives less of the total power as its beamwidth decreases. In order to preserve the efficiency of the heater array, grating lobes must be utilized in creating the AIM cloud or the array can not be heavily thinned. FIG. **15** shows an array with uniform spacing having grating lobes. FIG. **16** shows an array with randomized spacing which eliminates the grating lobes.

Although the invention has been described above with particular reference to certain preferred embodiments thereof, it will be understood that modifications and variations are possible within the spirit and scope of the appended claims.

What is claimed is:

1. A method for generating an AIM, comprising the steps of:

(a) creating avalanche ionization in the atmosphere using a heater antenna;

(b) refocusing said heater antenna to alter the altitude of said avalanche ionization by frequency shifting said heater antenna; and

(c) scanning said heater antenna to paint an avalanche ionization layer.

2. A method for generating an AIM as claimed in claim **1** wherein said heater antenna is focused in the near field.

3. An apparatus for generating an AIM comprising:

(a) a phased array heater antenna which is focused at an altitude to cause an avalanche ionization area to be created in the atmosphere;

(b) means for controlling frequency of individual radiators of said phased array heater antenna to refocus said altitude of said avalanche ionization area; and

(c) means for controlling phase of the individual radiators to scan said phased array heater antenna.

4. An apparatus for generating an AIM as claimed in claim **3** wherein said phased array heater antenna is focused to cause said avalanche ionization area to be substantially a line.

5. An apparatus for generating an AIM as claimed in claim **4** wherein said means for controlling phase moves said line substantially at a constant altitude and said means for controlling frequency moves said line to different altitudes.

6. An apparatus for generating an AIM as claimed in claim **4** wherein said phased array heater antenna is a rectangular array and said line is formed parallel to a long dimension of said rectangular array.

7. An apparatus for generating an AIM as claimed in claim **3** wherein said phased array heater antenna is focused to cause said avalanche ionization area to be substantially a point.

8. An apparatus for generating an AIM as claimed in claim **7** wherein said means for controlling the phase moves said point substantially at the same altitude and said means for controlling frequency moves said point to different altitudes.

9. An apparatus for generating an AIM as claimed in claim **3** wherein said phased array heater antenna is focused in the near field.

10. A method of generating an AIM comprising the steps of:

(a) focusing a phased array heater antenna at an altitude to cause an avalanche ionization area to be created in the atmosphere;

(b) controlling the frequency of individual radiators of said phased array heater antenna to refocus said altitude of said avalanche ionization area;

(c) controlling phase of the individual radiators to scan said phased array heater antenna.

11. A method of generating an AIM as claimed in claim **10** wherein said step of focusing causes said avalanche ionization are to be substantially a line.

12. A method of generating an AIM as claimed in claim **11** wherein said step of controlling phase moves said line substantially at a constant altitude and said step of controlling frequency moves said line to different altitudes.

13. A method of generating an AIM as claimed in claim **11** wherein said phased array heater antenna is a rectangular array and said line is formed parallel to a long dimension of said rectangular array.

14. A method of generating an AIM as claimed in claim **10** wherein said step of focusing causes said avalanche ionization area to be substantially a point.

15. A method of generating an AIM as claimed in claim **14** wherein said step of controlling phase moves said point substantially at the same altitude and said step of controlling frequency moves said point to different altitudes.

16. A method of generating an AIM as claimed in claim **10** wherein said step of focusing is performed in the near field.

(57) ABSTRACT

This invention converts inertial impulses into electric currents. Specifically, it converts impulses created by the impacts of high-energy particles from the Sun and other cosmic sources into the Earth's Magnetosphere and the varying D, E, F1 and F2 layers of its Ionosphere to controlled electric currents. This invention presents a new method of utilizing energy from the Sun and other sources of high energy articles as a virtually, inexhaustible, alternative-energy source for the world.

HARMONIC ENERGY EXCHANGE DEVICE

BACKGROUND OF THE INVENTION

[0001] 1. Field of Invention

[0002] This invention relates to the conversion of impact energies created by the collision of high-speed cosmic particles and electromagnetic radiations with "Earth's Outer Layers" to produce inertial waves in the dielectric Troposphere which are subsequently converted into electricity by this invention.

[0003] The term "Earth's Outer Layers" refers to: Earth's Magnetosphere, Van Allen Belts, Ionosphere, Mesosphere, and Stratosphere as illustrated in FIG. **2**

[0004] 2. Description of the Prior Art

[0005] One day while reading an old scientific magazine I saw a small article on the research of Dr. John Trump of MIT (the basis for an electrostatic generator patented later by Onezime P. Breaux in U.S. Pat. No. 4,127,804). The article talked about a series of experiments which Dr. Trump had performed with a 2-plate, capacitor in a vacuum dielectric. Briefly, he discovered that by varying the distance between the two plates one could produce current flows in one direction or the other between either of the plates and ground.

[0006] The Solar Wind strikes "Earth's Outer Layers" constantly as do many other cosmic particles. At any given instant of time, the vector product of these impacts produces either a net pressure increase or decrease in the Troposphere. This creates random waves of pressure in the "Earth's Outer Layers" as one charged "plate" moves in relation to the oppositely-charged Earth's surface as the other "plate". This variation of pressure in the "Earth's Outer Layers" is equivalent to moving an outer "plate" back and forth toward the Troposphere and the Earth's surface as the inner "plate"—thus giving rise to variations in voltage on both "plates". In this case the Troposphere (see FIG. **2**) acts as the dielectric medium instead of the vacuum in the Trump experiments. Furthermore, the Troposphere, itself, is also compressed and decompressed by these random waves of pressure on the "Earth's Outer Layers". Thus, I reasoned if one could create a charged envelope or field of sufficient voltage within the Troposphere, one could convert these random pressure waves in the dielectric Troposphere into current flow on the Earth's surface.

[0007] As "Earth's Outer Layers" surround the planet, any impact waves propagate throughout all of them when they are present—even to the nighttime side of the planet. Thus, I also reasoned one could extract power from these impacts anywhere on Earth's surface or in its atmosphere whether it be day or night. The pressure waves on the dark side of Earth would be less energetic than those occurring on the daytime side because the nighttime layers of the Ionosphere are compressed so much that the D-Layer of the Ionosphere disappears at night and the F1 and F2-Layers of the Ionosphere combine into one F-Layer. I calculated the available energy from these impact waves would be significantly less by 30-45% depending upon one's location on the night side of the planet in respect to the terminator.

[0008] Many years ago around 1900 Dr Nikola Tesla built and tested a device to extract energy from the Sun using an apparatus which forms part of my own invention (see U.S. Pat. Nos. 685,957 an 685,958 dated 5 Nov. 1901).

[0009] Subsequently, Dr. Thomas Henry Moray, another inventor and student of these Tesla patents made a device which apparently accessed the same source of energy but with a method different than my own. As Dr. Moray was never granted a patent for his device I cannot be certain that his work is considered prior art but I list it here as part of my due diligence. Apparently, he had trouble explaining the source of energy his device was converting to the patent reviewer and was, thus, not granted a patent for his impressive work. Dr. Moray's public disclosure of certain aspects of his invention are public knowledge through his published lectures and his book, "The Sea of Energy in Which the Earth Floats'—published in 1931.

[0010] Since the beginning of the 20th Century mankind has been looking for new sources of electric power to feed the ever-increasing energy demands of the human population. In the last half of the 19th Century coal, whale oil, human and animal labor, moving water, wind and wood were main sources of energy. However, in the first quarter of the 20th Century mankind began to use more electricity produced by hydroelectric generators and other generators producing electricity by combustion of fossil fuels. With increasing use of gasoline engines and the increasing use of electrical appliances the demand for electricity accelerated the addition of heat and greenhouse gases into the Earth's ecosystem.

[0011] In the last half of the 20th Century many forward-thinking individuals began looking for alternate energy sources to reduce the emissions of greenhouse gases. All of the alternate energy systems investigated and/or developed in the last 56 years have had significant drawbacks to their usage as the main energy supply for the needs of humanity.

[0012] Some of those alternate energy systems were nowhere near as efficient as the existing systems. Some of the alternate energy systems still introduced extra heat into the environment like the existing fossil fuel and nuclear energy systems. And, yet, others produced even more greenhouse gases than the existing energy systems. Some of the new systems used food resources to produce combustible fuels which, consequently, reduced the food resources of the planet. Among the leaders in the new energy sources was and is nuclear energy which produces extra heat, toxic wastes and materials which can be used in nuclear weapons. Hydroelectric energy sources do not add heat to the ecosystem but they are not an inexhaustible resource as they depend upon rainfall which is diminishing as global warming increases. Wind energy resources do not add heat to the ecosystem but they are not constant and require expensive conversion and storage equipment.

[0013] The ideal energy source for mankind will not add heat to the planet's ecosystem, will not produce by-product green house gases; will not deplete our food and water resources; will not produce toxic wastes; however, it will be portable, self-replenishing and constantly available in real time anywhere on Earth and in useful quantities.

[0014] Our major source of natural energy on Earth is the Sun. Energy from the Sun enters the Earth's ecosphere by particle bombardment, radiated electromagnetic energy, gravitational variations and magnetic processes. Mankind has developed various methods of capturing energy from the Sun already. Silicon-based solar cells convert light in a narrow bandwidth into electron flows. These cells are—at most—only 50% efficient and only work when the Sun is shining on them and at an optimum angle. Wind turbines only work when there is wind to power them and are—for the most part—not portable. Devices to convert wave action in the oceans only work when there are waves created by the wind and tidal effects caused by gravitational variations; and they are not portable enough to be used in common transportation devices.

[0015] I concluded if mankind could find an inexpensive method of obtaining electricity from the Sun in some form that worked both day and night and which was already flowing into the Earth's ecosystem, we might be able to develop a clean and self-replenishing energy source which would add no extra heat to our ecosystem, would not alter our planetary albedo and might well be made in a portable form.

SUMMARY OF THE INVENTION

[0016] The Harmonic Energy Exchange Device (or "HEED") offers an interim solution to Earth's dwindling fossil fuel resources. It utilizes a previously untapped energy resource which exists throughout the known Universe. By the very nature of the invention, it only interrupts the flow of energy from the Sun and all the other cosmic sources of high-energy particles on their normal journey to the Earth by way of The Outer Layers.

[0017] The invention does not add energy to the normal thermodynamic equilibrium of the planet and its associated outer layers. The invention does not produce wastes—toxic or otherwise. It does not produce harmful gases; and in some embodiments it could even assist in the rebuilding of our thinning ozone shield. Use of this invention will eventually remove mankind's dependence on fossil fuels and create new occupations. It will be cheap enough that homeowners will be able to install their own HEED and sell back energy to the grid until such time as every home has their own HEED and civilization has completely weaned itself from the use of fossil fuels and nuclear energy in its current form.

BRIEF DESCRIPTION OF DRAWING

[0018] FIG. **1**: Is the preferred embodiment of the circuit diagram of my invention incorporating references to external stimuli which are used to activate the circuit. It represents a parallel tuned circuit to store the energy.

[0019] FIG. **2**: Is an illustration of the Earth and it immediate environment as a global capacitor where The Outer Layers form one plate and the Earth's surface form the other plate and both are separated by the Troposphere as a dielectric medium.

[0020] FIG. **3**: Is an alternate embodiment of the circuit diagram of my invention incorporating references to external stimuli which are used to activate the circuit. It represents the use of a series tuned circuit to store the energy.

DETAILED DESCRIPTION OF A PREFERRED EMBODIMENT OF THE INVENTION

[0021] Be it known that I, Harold Stanley Deyo, Jr, a citizen of both The United States of America and The Commonwealth of Australia, residing in the community of Pueblo West in Pueblo County, Colorado have invented an Harmonic Energy Exchange Device which converts dynamic pressures in the ambient media around Earth to controlled electric currents.

[0022] This invention as represented in FIG. **1** is unique in that it is designed to extract electricity from random pressure waves propagated in the Troposphere **14** by impacts of the solar wind and other cosmic particles with the Earth's "The Outer Layers" **22** of FIG. **2**.

[0023] In FIG. **1**, the Troposphere **14** in its rest state is represented by the line of "+" marks **14**. The convergent or compression state **12** of the random waves in the Troposphere **14** is represented by the lower line of dots while the divergent or decompression state **13** of the random waves in the Troposphere **14** is represented by the upper line of dots. The preferred embodiment of my invention FIG. **1** is a method of coupling a parallel, resonant, electrical circuit to these random pressure waves to extract electricity from them.

[0024] As Dr John Trump's research and Onezime P. Breaux's U.S. Pat. No. 4,127,804 show, when one plate of a charged capacitor is moved closer to or farther from the other plate of that capacitor a voltage change appears on both plates of that capacitor. Furthermore, the electric field gradient between those plates changes as the plates are moved in this manner. Thus they have described a method of converting mechanical energy into electrical current by simply varying the plate spacing over time which can be expressed as ds/dt where "ds" is the change in spacing and "dt" is the change in time.

[0025] As illustrated in FIG. **2**, The Outer Layers can be viewed as one plate of a capacitor comprised of the Earth's surface itself as one plate **21** and Earth's outer layers as the other plate **22** where the Earth's Troposphere **23** serves as the dielectric medium separating the two plates. There is a charge between these plates which varies extremely rapidly but not with a constant period. At any given instant, the vector product of all the impacts by the cosmic particles with The Outer Layers **22** will create a pressure wave in The Outer Layers **22** which will manifest in the Troposphere **23**. Whatever that vector product is, it will alter the field gradient in the dielectric Troposphere **23**. That alteration will either increase or decrease the effective spacing between "plates" **22** and **23**.

[0026] In order to capture and convert the resulting voltage variations produced at or near the Earth's surface **21** of FIG. **2**, this invention creates its own, localized stress field **3** of FIG. **1** established in the Troposphere **23** of FIG. **2** with a charged, conductive surface **1** of FIG. **1** which is encased in high-voltage insulation **2** of FIG. **1** and extending into the Troposphere **23** of FIG. **2**.

[0027] In FIG. **1**, a series of high-voltage, starting pulses is applied across points **4** and **6** on opposite sides of a capacitor **5** to create the localized stress field **3**. As these high-voltage starting pulses are applied, the parallel resonant circuit formed by inductor coil **7** and variable capacitor **11** both referenced to ground **8** is stimulated into resonance within the bandwidth determined by the values of these circuit components. Tuning of this circuit is effected through variable capacitor **11**. The high voltage charge on conductive surface **1** of FIG. **1** is maintained by the parallel tuned circuit formed by inductor coil **7** and variable capacitor **11**.

[0028] Then as the random, pressure waves propagate throughout the Troposphere **23** of FIG. **2**, the localized stress field **3** of FIG. **1** is oscillated by the compression wave front **12** and the decompression wave front **13**—both of FIG. **1** which creates voltage changes on capacitor **5**.

[0029] In FIG. **1**, the resulting voltages changes on capacitor **5** will add energy to the parallel resonant circuit formed by inductor coil **7** and variable capacitor **11** which acts as a tank circuit to store the energy which has been passed to it. As energy builds in the parallel circuit the voltage of the circuit rises until a spark discharge occurs across the gap **9** also referenced to ground **8**. The current will only discharge in one direction as determined by diode **10**. The circuit will work without diode **10** but a diode is used here as one method to keep from draining all the energy from the tank circuit when a discharge occurs.

[0030] This resonant circuit can be tuned to various bandwidths to maximize the efficiency of the conversion process depending upon location of the device, time of day, temperature variations, relative humidity and other variables in the ambient Troposphere **23** of FIG. **2** around the conductive surface **1** of FIG. **1**. A resistive load to extract power from the resonant circuit can be used instead of the spark gap **9** of FIG. **1**.

[0031] This preferred embodiment uses a parallel, tuned circuit to access a wide range of frequencies usually to be found in the range of 4.5 to 7 MHz. This range encompasses the major, naturally-occurring, resonant frequencies found in the ionosphere.

[0032] A second embodiment of this invention as shown in FIG. **3** replaces the parallel tuned circuit formed by inductor coil **7** and variable capacitor **11** in FIG. **1** placed in parallel to each other and referenced to ground **8** in FIG. **1**. This second embodiment forms a series tuned circuit formed by inductor coil **7** and variable capacitor **11** in FIG. **3** placed in series to each other and referenced to ground **8** of FIG. **3**. It differs from the preferred embodiment only in the placement of variable capacitor **11** of FIG. **3** so that it is in series with coil **7** of FIG. **3**.

[0033] This embodiment limits the frequency range and, hence, the energy the system will store when compared to the preferred embodiment. It produces higher voltages across the spark gap **9** of FIG. **3** than those produced in the preferred embodiment across the spark gap **9** of FIG. **1**.

1. An apparatus for coupling to the pressure waves created in the Earth's Magnetosphere and the varying D, E, F1 and F2 layers of its Ionosphere by the impacts of various high-energy particles from both our Sun and other cosmic sources.

2. An electrical circuit for harmonically converting the pressure waves described in claim (**1**) into periodic electric current discharges.

Harvesting power from WiFi signals

RCA
Airnergy
WiFi Hotspot
Power Harvesting
Battery Pack

At the recent 2010 International Consumer Electronics Show (CES), RCA introduced the Airnergy Charger which they claim is able to convert the energy in WiFi signals into electricity to power small devices. RCA demonstrated at CES that the Airnergy Charger was able to charge a BlackBerry from 30% to full charge in around 90 minutes using only ambient WiFi signals at the show for power.

Perovskite Photovoltaics 2016-2026

The pocket sized Airnergy Charger has an internal battery for electricity storage. Power can be extracted from WiFi signals as the charger is carried around, or it can be left near a WiFi router at night to collect and store power for use the next day. Although this device would be a boon to the energy harvesting industry, some detractors suggest that the device would not generate a useful amount of power unless placed in the immediate vicinity of a high power broadcast.

RCA
Airnergy
WiFi Hotspot
Power Harvester

RCA aims to produce a battery with WiFi harvesting technology but in the meantime they say the USB Airnergy Charger will be available later this year for US$40.

Parasitic use of WiFi signals has already been employed by so-called WiFi Real Time Locating Systems RTLS ("Second Generation Active RFID") as detailed in the IDTechEx report Real Time Locating Systems 2009-2019. Here principles such as Received Signal Strength Indication RSSI from several WiFi nodes are used in conjuction with radio mapping to permit the tag to be located in 3D. However, the tag always contains a battery because the WiFi emissions are inadequate for the necessary data processing and transmission of derived information.

Joe Flynn's Parallel Path Magnetic Technology
Tim Harwood © 2003

There is a widespread opinion common to the mainstream academic community and also to various alternative scientific forums, that some kind of exotic new physics will be required to design and implement over-unity technologies. That is to say electrical motors, electrical generators, or other apparatus, which produce an excess of magnetic force or energy above the value actually inputted.

However, this has recently been experimentally demonstrated not to be the case, as I have validated myself in simple $20 experiments undertaken at home with parts bought from the local hardware store. It is the purpose of this article to educate readers that with care, thought, and a little work, it can be demonstrated that existing textbook physical law, freely allows for the extraction of excess electrical energy from magnetic systems.

The credit for this ground breaking research goes to Joe Flynn, who has been engaged in magnetic flux research for over 25 years now. His work is long standing, comprehensive, and in later years, well funded. It is reported $7m has been spent to date, with over $1m alone developing a revolutionary high performance magnetic motor. His equipment is validated, and apparently already in mass production for select customers. Since many lines of research have been formulated and explored by Joe Flynn, the following article presents only a brief summary of some of his best art apparatus, but is nonetheless sufficient to convey the basic ideas, and provide a framework within which one can undertake experiments.

Principals of Operation

The first illustration Figure 1 is taken from Joe Flynn's US patent 6,246,561, and explains a simple magnetic force multiplication experiment, which forms the basis for the Flynn magnetic art. If the windings on either side of the central magnet, which are normally connected in series, are properly pulsed, the field of the permanent magnet in the center, will be diverted to the opposite side of the core flux path provided. Or in alternative language, the side of the core that is pulsed, is demagnetized, relative to the field of the permanent magnet used in the apparatus. This is elementary textbook physics anyone can understand.

So what is surprising about this apparently simple apparatus, is that the armature on the side of the flux core, will contain 1.75 times more units of magnetic force, than could be manifested by the electrical input to the apparatus alone. Since the ability to arbitrarily move force from one point to another is the basis for motion or work, however simplistic, we therefore have a basis for a system that can be developed for practical technological purposes. Expressed in alternative language, we also have the capability to engineer a time varying magnetic field, without the need for moving parts, which will allow development of systems that output electrical energy. Both capabilities are highly desirable, and offer substantial opportunity for technical development.

Figure 1

U.S. Patent Jun. 12, 2001 Sheet 11 of 32 US 6,246,561 B1

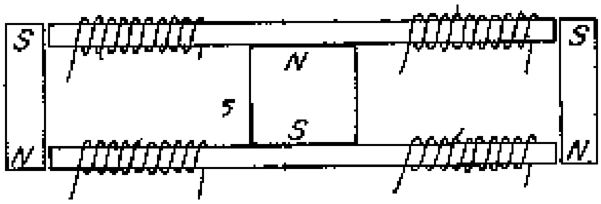

Fig. 16 B

1.75 times more force is delivered to the legs of the core
Than is provided by the electrical input to the control coils

Expanding upon this basic experiment, there is a second simple and logical improvement in layout illustrated in Figure 2, which should be obvious, but has been shown not to be the case. In this instance, the pulse is centrally located, and a dual flux field layout employed, which both demagnetizes the core relative to one magnet, and magnetizes it relative to the other. Since the two actions are complementary, the input required to manifest the flux switching effect is halved, therefore doubling 'efficiency.'

Figure 2

U.S. Patent Jun. 12, 2001 Sheet 30 of 32 US 6,246,561 B1

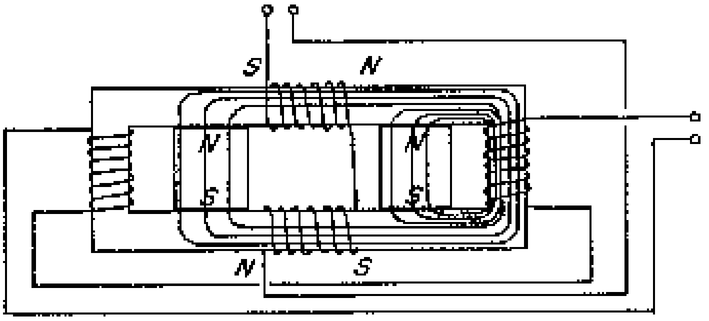

Fig. 45 Z

3.47 times more force is delivered to the legs of the core
Than is provided by the electrical input to the control coils

It should be noted that while the efficiency is doubled, the absolute output may not be significantly improved. This is because the major weakness of this effect and technology is flux saturation of the core, with values depending upon the specific properties of the B-H curve of the core material employed, limiting the absolute output of both layouts the same.

The previous statements are not required to be taken on trust, and simple experiments have been proposed by Joe Flynn, such that anyone can validate this effect for themselves. Figure 3 is a simple experiment taken from the Flynn website, that can be used to validate the principals put forward in this article.

An even simpler non electrical flux experiment was proposed by GM in the Parallel Path Egroup. My apparatus is illustrated in Figure 4. It is no more than magnets and steel staple strips, bought from a local hardware store for a total of under $10. The Parallel Path effect can be replicated with identical apparatus, at only a slight increase in cost and complexity, with the addition of a simple 12v polarity reversible power supply, such as those commonly sold to power computer speakers, among other household applications.

Conservation of Energy / Field Potential

One of the aspects of the Flynn technology people find most difficult to understand, is how you can have a device that delivers 3.47 times more units of magnetic force than is electrically inputted, yet not violate accepted principals of text book physics, as stated in the introduction. The key point here is magnetic fields do not gain energy - they are conservative. You can only ever obtain less energy from a magnetic field minus looses, than is in fact present. I feel this apparent puzzle can not be better explained, than by reference to Joe Flynn's own analysis of the experiment presented in Figure 3.

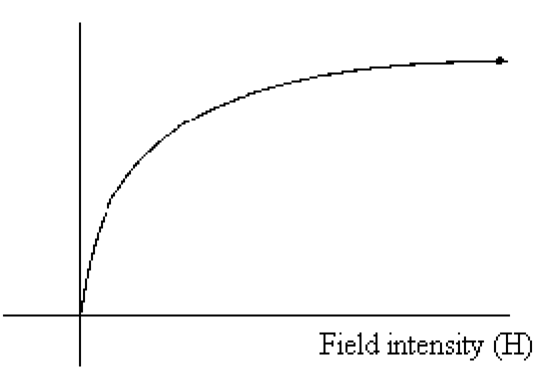
'*Since the Parallel Path System produced 3.47 times more force than the conventional system, with the same electrical input, it appears to violate conservation, this is only true when observed from a traditional view point. The system contains three flux producing sources (2 magnets and an electromagnet) which together are capable of producing a far greater force than is actually produced. All of the flux sources together can produce a force of 13.11 units, therefore in the physical sense a loss of 1 - (9.01 / 13.11) = 31% is realized.*'

So the system is 347 % efficient, in terms of delivered magnetic force compared to net electrical input, yet still conforms to the accepted physical principals of field conversation, by being only 69 % efficient, in terms of the fields present in the system. However surprising this result may appear, the analysis presented is in outline correct, with the difference between fields present in the system, and net electrical input, being the important concept presented.

Losses in the System

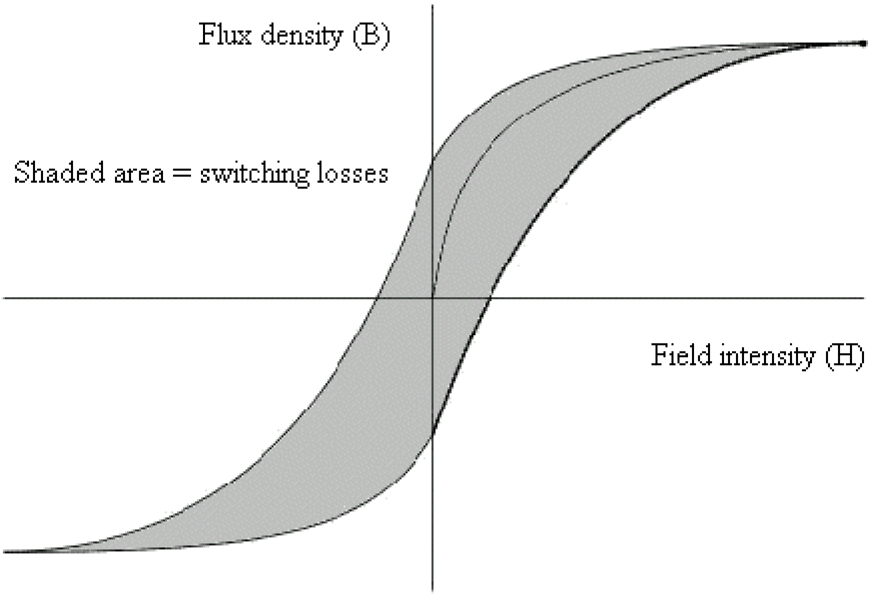
In order to optimise flux cores, an appreciation of the physics that underlies the transfer of flux within a core is required. The normal magnetization curve, or B-H curve, is a mathematical relationship between applied field intensity H, and resultant flux density manifested in the core B. It varies according to core material, and the curve will shift, if there is a starting magnetism within the core, such as that provided by the field of a permanent magnet. If the start magnetism is excessive, the core is saturated, and will not properly respond to the applied force H. A simple B-H curve is illustrated in Figure 5.

Figure 5



Hysteresis is a delay between applied magnetic force H, and resultant flux density B, that again varies according to material type. It also manifests as a delay between the termination of force H, and the manifestation of flux density B. So, the system will not turn on instantly, and will not turn off instantly, in simple terms. This is because the magnetic memory of the core, means a flux vector remains within it, even when the application of magnetic force H has been terminated. If we apply a reversed force H to the core, the basic B-H curve is now expanded as in Figure 6, with the memory effect also illustrated.

Figure 6



In order to return to the initial switched state, the remnance magnetism must now be overcome, hence input once in operation, will be greater than that required for the very first pulse. The area within the hysteresis curve gives a rough estimate for the amount of wasted energy, and along with other conventional sources of losses resultant in flux transfer within a core, is what reduces the efficiency of flux cores from maximum values of 2, or 4, down to values such as 1.75 or 3.47, typically.

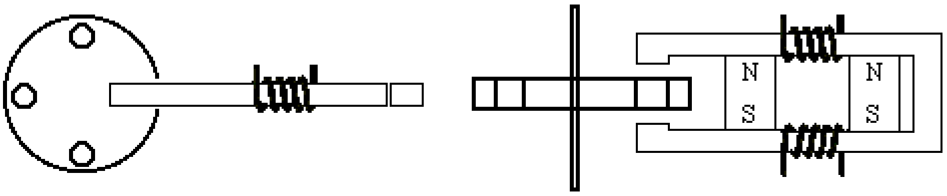
Motor Apparatus

Although numerous practical applications abound for this effect, electric motor design remains the most outstanding opportunity. To this extent, again a few simple images, should be sufficient to explain how the basic flux switching apparatus, can be turned into a highly efficient electrical motor.

The first motor shown in Figure 7 is one I have proposed to validate the flux switching effect at a most basic level. It illustrates the point made in the Flynn patent, that the armature of the core can be removed, and replaced with a motor flux path. This first motor is not claimed to be highly efficient, but it helps one to understand how the transition from simple flux core to motor takes place.

Figure 7

Simple Parallel Path Technology Demonstrator Motor



Designed to demonstrate core principals, not provide over-unity
4 magnetically permeable cores placed on rotor section
Flux is switched through core section on approach to armature section
When armature section is in register with rotor cores
Flux is switched back, and rotor core free wheels away from register

The next motor shown in Figure 8 is again taken directly from the Flynn patent, and illustrates the next intermediate step to motor design. The fields of the permanent magnets are alternatively switched from one side of the surrounding flux cores to the other, alternately interacting with N and S poles on the rotor, imparting motion to the central rotor shaft.

Figure 8

U.S. Patent

Jun. 12, 2001

Sheet 34 of 52

US 6,246,561 B1

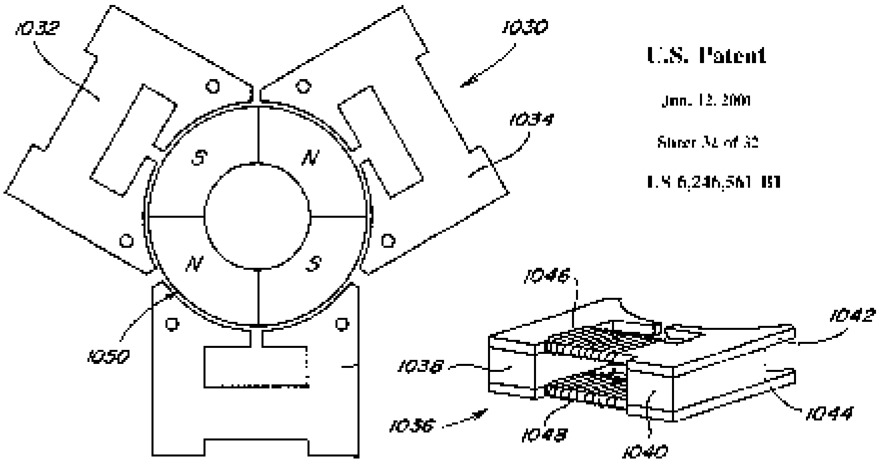


Fig. 49

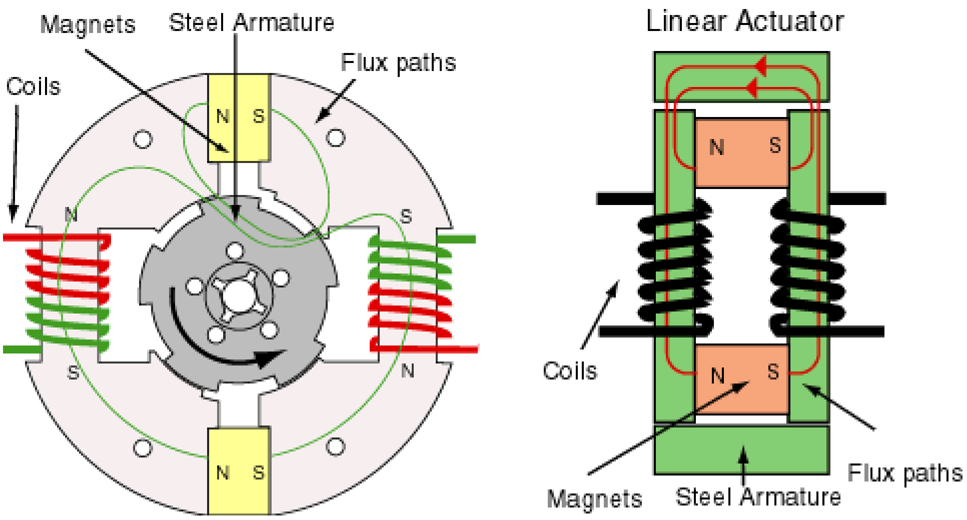
Fig. 50

With proper financial support, and the facilities to have metglas cores custom moulded, Joe Flynn was able to develop his final best art, shown in Figure 9. No detailed performance numbers have been released for this motor, whose precise characteristics remain proprietary to Joe Flynn at this time. But the optimisation is so expert, it is stated to posses certain exotic properties, such as cool ambient operation, even during prolonged periods of continuous load. This 'cold running' is said to be of great interest to the American military, as it offers excellent stealth performance characteristics.

Figure 9
Optimal Flux Core Motor Construction



Electrical Apparatus

Many readers will no doubt have noticed the similarity of the first illustration presented in this document, to the so called 'Tom Bearden MEG.' This is fair comment, and Joe Flynn has always highlighted this issue. However, it has been commonly stated Joe Flynn simply developed mechanical apparatus, and the MEG with its electrical functionality, is distinct art, more advanced than the mechanical Flynn apparatus. However, this is shown not to be the case by a careful examination of the Flynn patent, in which the following is stated in the 'Power Conversion' section:

'*The construction shown in FIG. 45A utilizes four control coils and a single permanent magnet and the construction shown in FIG. 45X uses two control coils and two permanent magnets. The flux that would normally be supplied by a primary winding is supplied by the static flux of the permanent magnet or magnets and the control coils convert this static flux into a time varying flux in a novel way. Both arrangements use two secondary coils, the secondary coils are placed in the region of the continuous flux path that would be occupied by an armature or rotor in the linear or rotary arrangements. The regions of the flux paths that perform work are the same in all cases.*'

'*By alternating the polarity of the control coils during one cycle, one working region experiences an increasing flux and the opposite region experiences a decreasing flux and during the next cycle the opposite occurs. This results in the induction of a voltage in the secondary coils that is decided by the magnitude of the change in flux in the working region and the time in which this change occurs. The novelty of this discovery is that the primary flux inducing the voltage in the secondary coils is supplied by the permanent magnet or magnets and is far greater than the flux supplied by the control coils.*'

Figure 10

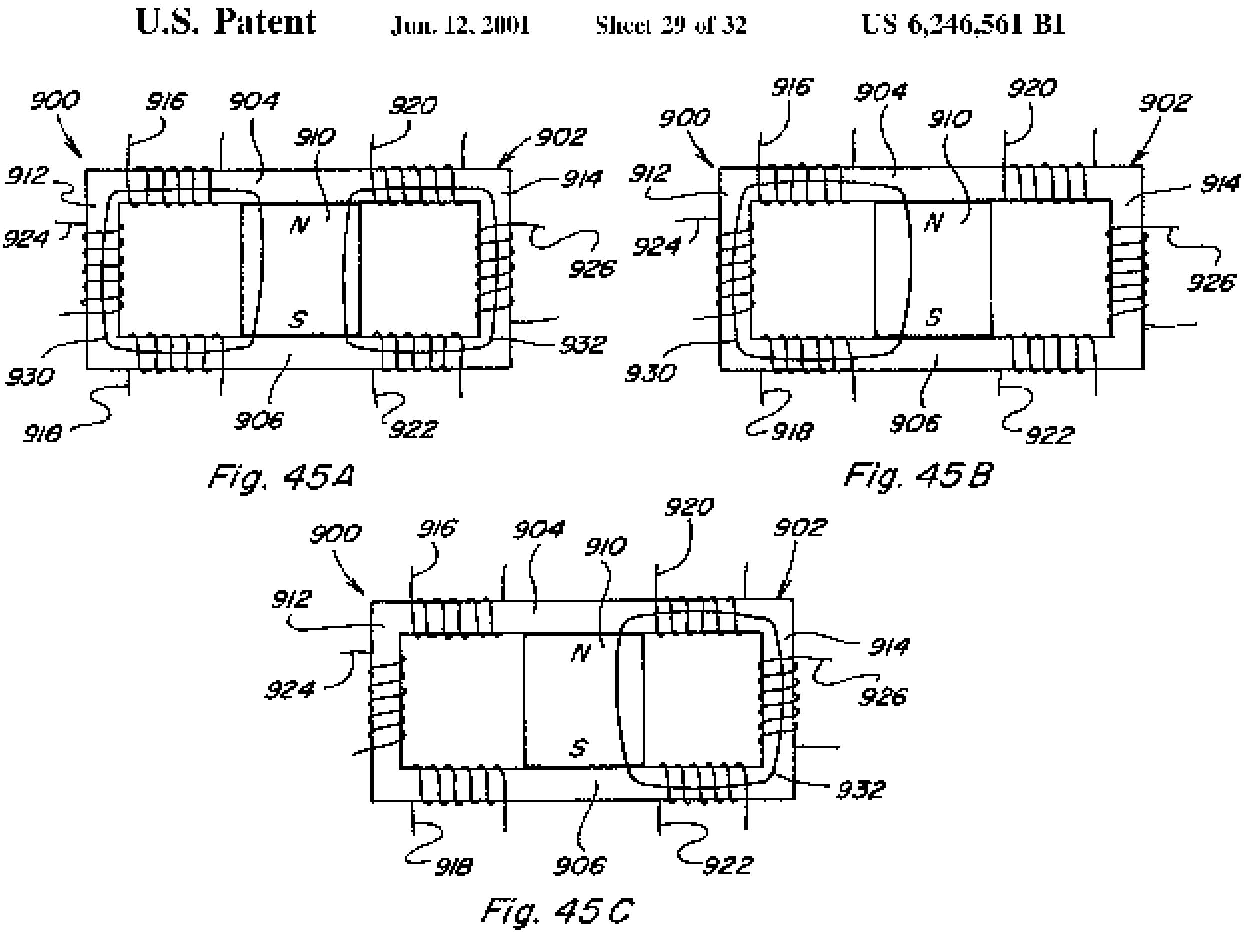


Figure 10 taken directly from the Flynn patent makes the point even clearer. Joe Flynn has also stated that his intellectual property rights will be robustly defended, by legal action if necessary, and he regards himself and his company as being in possession of exclusive rights to the so called 'MEG' unit.

As regards replication of electrical output orientated flux core devices, certain important details need to be stated. For example grade 8 ceramic magnets should be used, so as to avoid flux saturation of the core. A basic error, many early experimenters wasted time on. The requirement for strong magnets to obtain over-unity results, is as much of a myth, as the idea new physics is required.

But perhaps the greatest trade secret of the electrical devices, one which several lengthy non disclosure agreements are required to be signed before it can be disclosed, is that the input and output circuits must be closed in series. The disclosure of this technique, amounts to putting the basic MEG methodology fully into the public domain.

The reason for this circuitry requirement is obvious enough, with only a little analysis. If the output circuit is closed when the input circuit is activated, then the input energy simply leaks into the output circuit, as in an ordinary transformer. So no flux switching effect is manifested, and the field of the permanent magnet is static in time. Thus you have an ordinary transformer, with reduced efficiency, because of the core flux saturation effect provided by the permanent magnet.

This is one of the most important points to make about the Flynn apparatus. If you approach it as if it is a normal piece of scientific equipment, then proper optimisation is not greatly problematic. For example more turns on the output coils, simply means more voltage and less current, exactly as standard textbook equations predict. Increased input voltage enables faster switching speeds, a consequent greater rate of change of magnetic flux, resulting in higher absolute output, but only up to the flux saturation limit of the core material. Generally, problems only occur, if you imagine the effect is based upon exotic scalar type or vacuum energy physics, when in fact it is ordinary flux manipulation within a core.

Present Status of the Flynn Project

Initially Joe Flynn was remarkably open about his work and research. However, since performing a working demonstration of various advanced hardware samples for the American Department of Defence, little has been heard.

I want to clearly emphasize I do not speak for Flynn Research, nor am I in any way connected with Flynn Research, and by consequence, have no inside information whatsoever as to the present status of the project. But we all sincerely hope, that the project has not been swallowed whole by the American deep black military industrial research complex.

However, even if this is the case, it does not mean the technology is lost. Extensive and generous details have been provided by Joe Flynn of his research, both in his patent deposition, website, and other comments, such as to enable persons of scientific training and skill, to replicate the effects stated.

While replication of the electrical effect remains extremely demanding, the mechanical apparatus is very easy both to understand and replicate. There is no reason why professional scientists and home experimenters alike, can not build Flynn type flux core motors, and explore over-unity flux manipulation for themselves. The future has already arrived, and it is simpler and cheaper than anyone dared imagine to be possible.

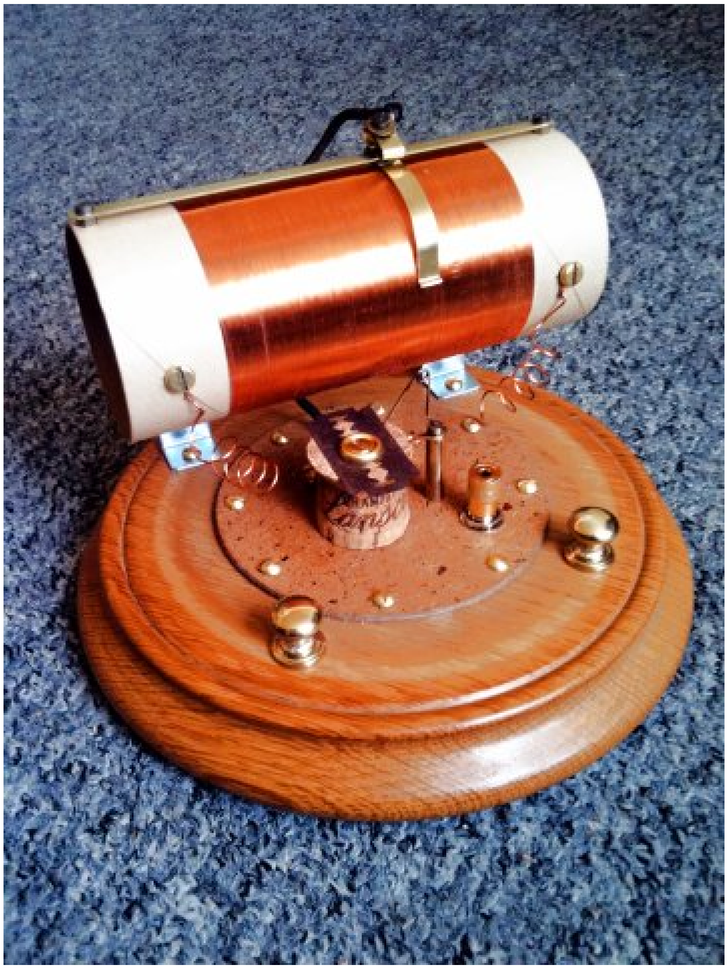
Jools' Razor Blade Crystal Radio

Foxhole Radio



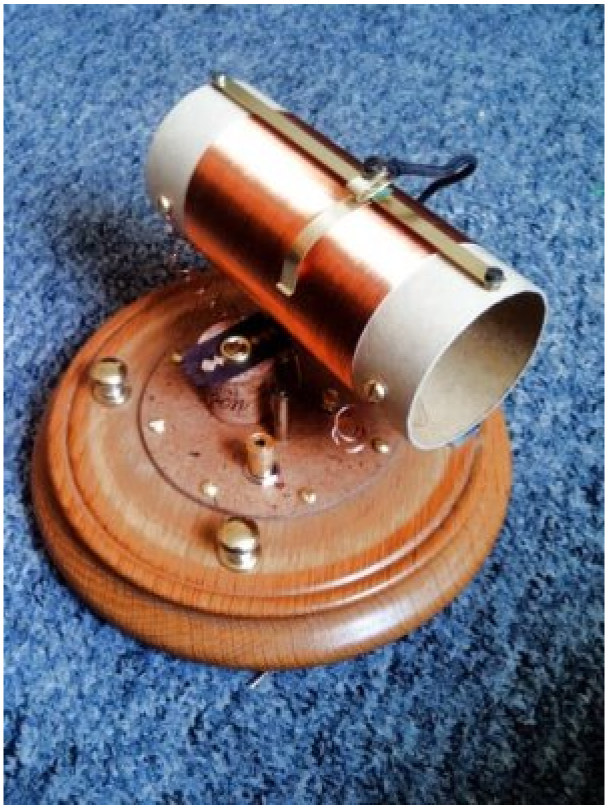
A- (javascript:changeFontSize(-1)) A+ (javascript:changeFontSize(1))

I am strictly a 'newby' in that my speciality is foxhole radios. If you might be interested in those, I have a whole load of photos of various contraptions I have built that work with razor blades and such like. I wanted to get right back to the beginning of the science and have been successful in building sets that work with a collection of household items.

I believe that the magic begins with the core science, and when you hear music and voices coming through on a set made from the contents of a kitchen drawer, it makes you realise how amazing the whole genre is.

In time, as I get the mechanical ability to make more 'beautiful' radios I will take more photos.

I am not a ham radio member, but I have been a 'commercial radio' broadcaster / presenter. So, I'm a bit of an oddball,



You can see from the schematic that it's based on a 1920's design and is a very basic design. However, with the variable coil wired into the aerial, there is a fair degree of tuning available however, the local BBC station is pretty dominant throughout as I only live about two miles away from their main transmitter. I took a 'short cut' route by linking the aerial wire directly into the roof TV aerial socket (not a particularly safe idea, don't try this at home) and got a surprisingly good, interference-free sound.

The audio quality is slightly sibilant but on the whole, very listenable. I uploaded a couple of sound files to demonstrate just how clear the sound is - Sound File 1 (http://audioboo.fm/boos/484097-listening-on-a-razor-radio) Sound File 2 (http://audioboo.fm/boos/484118-interacting-with-local-radio-using-the-power-of-a-basic-home-made-radio) I emailed the show and the DJ gave me a name check, just to prove it was working.

In terms of construction, I used things I could find in my shed (a cheeseboard, nuts, bolts, brackets, door handles) and the whole thing took about two days to complete. The only tools required were: a drill, a soldering iron, a screwdriver set, a pair of pointed pliers and a pair of scissors.

The luckiest find was a pack of 'Gillette Blue' razor blades which I picked up at a car boot sale for fifty pence, but I found it very hard to locate the 'sweet spot' (which was usually on or around the lettering) so I eventually used a rusty blade from my dad's old shaver. This worked best when one contact (the mounting post) was linked directly to the flat rusty surface and the 'cat's whisker' (a brass safety pin) touched the blade edge. This arrangement worked perfectly at any point along the blade so long as a tight contact was made. Other references describe using the point of a hard pencil 'lead' mounted on the safety pin as the contact point but I found this to be not only fiddly but quite ineffective (and the lead kept breaking).

I mounted it with a standard headphone socket so that my daughter could play it through her computer (and so I could make recordings of the various tests and programmes I heard). That was a decision of convenience.

I don't have a website dedicated to radios, but I am a writer and in the middle of a novel about a radio star from the 40s and 50s. The best link (if at all) to use would be to the hub of that creative pursuit - http://www.kooshrecords.co.uk/reg/ (http://www.kooshrecords.co.uk/reg/) Also - happy to show this email address as a contact.

As I get chance to take other photos of these 'foxhole' radios, I'll send them over for your perusal. There's some 'wacky' stuff! I hope you like the 'enthusiasm' and boy scout innocence inherent in these designs (which was my intention: to make a device capable of hearing radio without any deep scientific knowledge, skills, equipment or resources. The kind of radios that boys in the 20s would have made.)

Best regards
Jools

Herman P. ANDERSON
(1918-2004)

Herman P. Anderson Technologies, LLC
PO Box 2014
Brentwood, TN 37024-2014

Herman and his water-powered Chevy Cavalier.

by James Allen

He could drive it, but he was not allowed to sell any, or manufacture his discovery in the State of Tennessee. Why not?

Herman's special patented sparkplugs, similar to Stan Meyer's plugs.

Herman has consulted with Nasa and the US Airforce on some of our country's most important Top Secret Projects including the first US satellite in space, the SR-71 Blackbird, the Stealth Fighter/Bomber and Starwars. Herman worked closely with Dr. Wernher von Braun testing hydrogen powered rocket engines, and he also worked with engineers at the now famous Skunk Works, the Jet Propulsion Laboratory, JPL, and Cal Tech. While in the Air Force during WWII, Herman served as a fighter pilot, a flight instructor and bombardier trainer. He was certified in and flew 23 different airplanes during this period.

Herman believed in a Hydrogen Future and FREE fuel!

Herman's 1971 Ford LTD converted to run on hydrogen or gasoline, on display in the Water Fuel Museum in Lexington, KY. In a video interview with the inventor, he explains that ambient air is mixed with hydrogen (not oxygen) and a micron-sized fog of water mist (to mimic gasoline's burn), introduced in the same way propane gas is on a propane conversion. In fact, the LP regulator and LP aircleaner assembly are the same as on a propane vehicle. The butterfly in the carb, as in an LP system, now serves as the intake air control. The rest of the function of the gasoline carb is not used. He claimed greater power than gasoline, and 38 miles per gallon of water. As far as quantity of hydrogen produced, he produced enough gas from his electrolytic chamber to need a cut-off switch connected to a pressure gauge to stop gas production when it was no longer needed while driving. In other words, instead of producing more or less gas on demand, as some systems do, it appears his system always produced the same amount, but was turned on and off as needed. He emphasized that deuterium (heavy water) was essential to his approach, doubling the density of the hydrogen, making it twice as powerful. He also used high voltage, 70,000 volts to be exact, from two custom-made coils, to effect rapid separation of the component gases, a process which he calls 'radiolysis.' The 70,000 volts constitute what he calls a 'soft' x-ray, not radioactive but in need of shielding, in-between a microwave oven and a 'hard' x-ray. He was authorized by the state of Tennessee to drive his car as they recognized that he knew what he was doing with such technology. I view his prototype LTD as good proof of a watercar for those who doubt that the technology is even possible, but not necessarily the best approach for you and me to pursue. He accomplished his invention along the lines of his expertise, the field of ionics; others have approached it differently with less controversial technology and have been equally successful.

My thoughts about Herman

Herman's 1978 Fort LTD came to be known as The Green Machine. Using a modified propane carburetor, Herman converted the LTD to run on hydrogen in 1980. Due to the low mass energy density of hydrogen, Herman was only able to get a little more than half power from the engine with this traditional induction system.

Because Herman only used a single cell, I believe you need to do the 3 cells hooked up in series like Archie Blue, Dingel's and Peter's design. Use - 3 - 4"dia. SS tubes , 8" long (cells) welded together. Put your series of SS plates inside each cell. gas lines coming out the top through a check value to the bottom of the next cell. Use rubber caps ends with hose clamps so if it ever blows it just blows the caps off and the water is drained and your mild explosion is over with.

You need more molecules of hydrogen clustered together as they pass thru 3 cells then into the IMPCO propane fuel injection carburetor. In gasoline SAE words a higher octane of hydrogen (ortho hydrogen) before it enters the fuel injection chamber. first H2 and O, then H4 and O2 then H8 and O4?? Who is the mathematician here? I'm not him. Peter can tell you.

There is para-hydrogen and ortho-hydrogen molecules. Ortho-hydrogen molecules will cluster and stick together, as they pass through 3 cells or more they cluster together more and more, their proton travels in the same direction, when finally sent to the combustion chamber they have 2-1/2 times the explosive power than gasoline!

Para-hydrogen are hydrogen molecules that will run together but have repelling protons to each other, therefore the clustering does not happen, they are less combustive than ortho-hydrogen. If you produce ortho hydrogen, then this also creates deuterium in which is what you want. deuterium build up on the cylinder walls, values helps oxidation from happening.

Now Stan used one tall wide cell with 3 tubes inside one large tube. 12" diva. and about 24" tall. Go look at his files.

To increase the power of the hydrogen, he irradiated it making deuterium. The extra proton was more than enough to allow the engine to achieve full power. It is good to get Deuterium built up in your piston walls, from the hydrogen so the water exhaust will not rust out the motor. They say AMSCO synthetic oil helps deal with the water in the oil better, helps it vaporize the water molecules.

Unfortunately, state officials decided the radioactive source under the hood would not be safe for widespread use. They did however allow Herman to continue driving the car and he put nearly 30, 000 miles on the car running on hydrogen. Realizing the technology could be improved, Herman went back to the drawing board.

It is kinda of ironic in that is exactly what a Ballard fuel cell is also doing, when in use in the new Hybrid Cars. The Ballard Fuel Cell is radioactively produce hydrogen to burn mixed with the air and the gasoline. The new hybrid cars are just as safe, except they use 1/2 gas and 1/2 electric. The Hybrids also contain radioactive batteries. The only difference was Herman's Wonderful car ran for FREE and with the new hybrid cars, you still have to PURCHASE the GASOLINE.

Yes the Mean Green Dancing Herman Machine was in the heart of every reader passing by with a BRAIN. Addicted to oil you drive to work, paying the largest corp. the largest profit in American history ever! Last quarter of 2004's profit from Exxon/Mobil exceeded the record for the largest quarter profit of 8 billion dollars. We are all guilty, unless you walk to work ride a bike, or enjoy an electric train.

The Green Machine also employed onboard electrolysis, meaning that to fill the gas tank, Herman would pour in distilled water.

and a little se cert Electrolyte KOH (1-5% solution to water, is all)

Yes there is a car that "runs on water." The car is now parked in the research facilities at MTSU.

Just like the TESLA statue at Niagara Falls, NY, it is way off to the side. And Edison's bust is real big in the middle with lights shinning on him. and he didn't even invent AC electricity, he was angry with Tesla's invention of AC, because it made his DC look non efficient. Today in all our households, we use AC electricity. It could have also been FREE wireless electricity. J.P. Morgan quit funding Tesla's FREE electricity Tower, because he could not find where to put the meter.

Next 10,000 people with water powered cars can join the STAN MEYERS 10.000 DUNE BUGGY PLANET MARATHON CLUB.

> All truth passes through three stages: First, it is ridiculed; Second, it is violently opposed; and Third, it is accepted as self-evident. -- Arthur Schopenhauer (1788-1860)

Fuel System for Internal Combustion System and Adapter for Use in Same

USP # 5,852,993

1998-12-29

Applicant: HERMAN P ANDERSON TECHNOLOGIES (US)
Classification: - international: F02B43/00; F02M21/02; F02B43/00; F02M21/02; (IPC1-7): F02M57/06; - European: F02B43/00; F02M21/02A
Also published as: US6119651 (A1)

Abstract -- The internal combustion engine fuel system described includes a structure for mixing the alternative fuel, preferably hydrogen, with oxygen in ambient air to stratify the fuel. The system includes an adapter, and the adapter includes a housing mounted between spark plug and cylinder of the internal combustion engine. A plug is placed within the housing. The plug has ridges or grooves on its outer surface that act as mixing structures. Thus, when hydrogen is introduced into the adapter housing it is mixed with ambient oxygen within the chamber as it flows over the plug. The mixing structures in the housing create a vortexing action as the hydrogen flows over the plug and towards the cylinder of the engine. An electrode protrudes from the plug towards the cylinder. The electrode is preferably platinum and generates the necessary spark to create combustion of the hydrogen/air mixture adjacent to the cylinder to thereby power the cylinder in the engine. A platinum electrode is preferably used because it enhances a catalytic conversion of combustion by-products to more environmentally compatible products.

Description

BACKGROUND OF THE INVENTION

The present invention relates generally to a fuel system for internal combustion engines that enables the invention to utilize alternative fuels; and, more particularly to an improved fuel system for an internal combustion engine and an adapter for use in same.

The problems of air pollution caused by automobiles, lawn mowers and other vehicles that have internal combustion engines powered by gasoline is well documented. This problem is particularly described in an article in the San Diego Union Tribune, Wednesday, Sep. 25, 1996 and in Popular Science, August, 1996. Indeed, under the Clean Air Act, in the next few years cars that do not run on standard fossil fuels like gasoline will be required in several states. Currently, there are no vehicles available to meet this need.

Thus, it will be appreciated by those skilled in the art that there has been a push to seek other fuels for use in internal combustion engines. These fuels include methane, propane and gasohol.

Hydrogen has also been characterized as a promising fuel source. See Department of Energy publication entitled "Hydrogen Fuel", printed in 1978, U.S. Government Printing Office, U.S. Department of Energy, Office of Public Affairs, Washington, D.C. 20585. Particularly, the graph presented in FIG. 6, which is copied from this publication, shows the potential for hydrogen in BTUs/Lb. However, the mass energy density for hydrogen is low; and thus, hydrogen needs to be compressed before its energy potential can be realized. No prior art fuel system has been able to capture the energy of hydrogen.

Several fuel systems for use with hydrogen have been proposed. Examples are described in U.S. Pat. Nos. 4,167,919; 4,253,428; 4,016,836; 4,178,882; 5,222,993; 5,085,176; and 5,085,176. The problem with these prior art fuel systems is they cannot can take advantage of the alternative fuels to generate sufficient power from the fuels to drive an internal combustion engine for use in a lawn mower, automobile or other vehicle. As noted above, this is a particular problem when hydrogen is used as a fuel. Additionally, the prior art systems do not address the problem of back fire, i.e. undesired explosion of the fuel in the cylinder during the exhaust stroke of the internal combustion engine.

What is needed, then, is a fuel system for an internal combustion engine that provides a way to generate sufficient power from the alternative fuels and that reduces backfire problems. Such a system is lacking in the prior art.

SUMMARY OF THE INVENTION

It is an object of this invention to provide an improved fuel system for use with alternative fuels.

It is a further object of this invention to provide an improved fuel system for use particularly with hydrogen, and particularly to enhance the mass energy density of hydrogen.

It is still a further object of this invention to provide an adapter for use in a fuel system for an internal combustion engine that enhances the power obtained from the alternative fuels.

It is still a further object of this invention to provide an improved fuel system for an internal combustion engine that does not present the environmental hazards of a standard gasoline engine by providing reduced or zero emission of environmentally harmful gases.

It is yet a further object of this invention to provide an improved fuel system for an internal combustion engine that can use an alternative fuel and can use gasoline to facilitate the transition from gasoline to alternative fuels.

It is yet a further object of this invention to provide an improved fuel system for an internal combustion engine that reduces backfire problems.

It is yet a further object of this invention to provide an improved fuel system for an internal combustion engine that reduces backfire problems by cooling the electrode in the spark plug with the hydrogen gas fuel.

It is still a further object of this invention to provide an adapter for use in a fuel system for an internal combustion engine that enhances the power obtained from the alternative fuels.

It is yet a further object of this invention to provide a direct injection fuel system wherein fuel is injected directly into the cylinder.

It is yet a further object of this invention to provide a way to convert the standard induction fuel system of a lawnmower to a direct injection fuel system wherein fuel is injected directly into the cylinder.

It is yet a further object of this invention to provide a way to convert the indirect injection fuel system of an automobile to a direct injection fuel system wherein fuel is injected directly into the cylinder.

The internal combustion engine fuel system of this invention includes a structure for mixing the alternative fuel, preferably hydrogen, with oxygen in ambient air to stratify the fuel. The term "alternative fuels" is known in the art and is meant to refer to fuels other than conventional gasoline.

The invention comprises an adapter, the adapter including a housing mounted between spark plug and cylinder of the internal combustion engine. A plug is placed within the housing. The plug has ridges or grooves on its outer surface that act as mixing structures. Thus, when hydrogen is introduced into the adapter housing it is mixed with ambient oxygen within the chamber as it flows over the plug. The mixing structures on the plug create a vortexing action as the hydrogen flows over the plug and towards the cylinder of the engine.

An electrode protrudes from the plug towards the cylinder. The electrode is preferably platinum and generates the necessary spark to create combustion of the hydrogen/air mixture adjacent to the cylinder to thereby power the cylinder in the engine. A platinum electrode is preferably used because it enhances a catalytic conversion of combustion by-products to more environmentally compatible products.

Thus, the combination of the compression action generated by the conventional piston and push rod within the cylinder of the engine in conjunction with the hydrogen/air mixing structure that vortexes the hydrogen/air create compressed hydrogen that is mixed with a combustion facilitator, i.e. oxygen in the ambient air to enable the system of this invention to capture the abundant energy found in hydrogen fuel.

The enhanced mixing capabilities of this invention is also adaptable for use with other alternative fuels such as natural gas, alcohol, propane and the like.

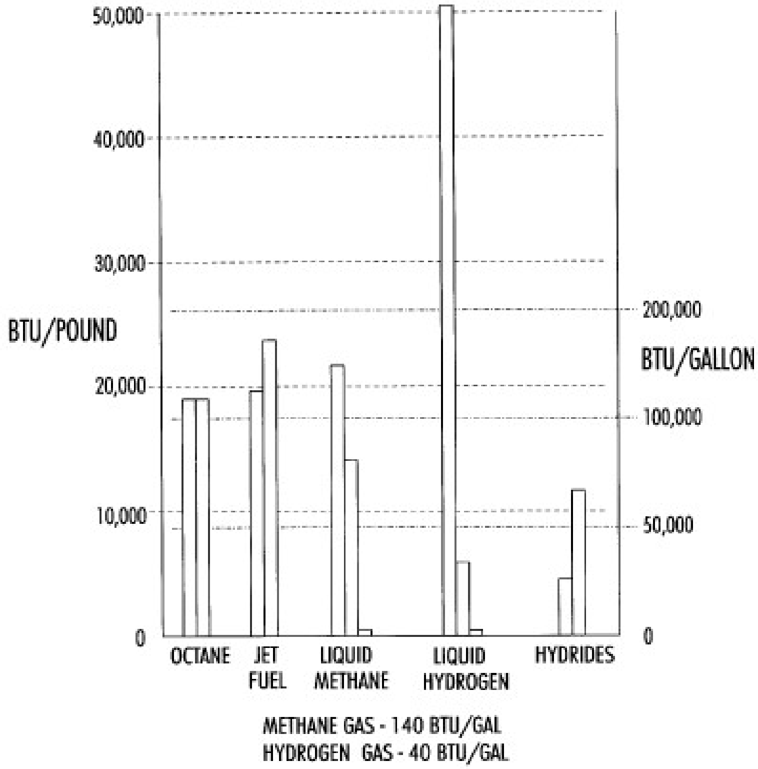

FIG. 6

DESCRIPTION OF THE PREFERRED EMBODIMENT

Referring now to the drawings, wherein like reference numerals refer to like parts throughout, the fuel system is referred to generally at 10. The fuel system of this invention is contemplated for use with an internal combustion power system, such as an internal combustion engine or such as a home heating system. Fuel system 10 is portrayed in this case as connected to a standard lawn mower. The lawn mower is shown in phantom at 12 in FIG. 1. The lawn mower is a conventional lawn mower as can be purchased from a company such as Murray of Ohio. The internal combustion engine in the lawn mower is a standard 4-cycle engine with two cylinders and develops 18 horsepower. A suitable example can be purchased from Briggs & Stratton, Milwaukee, Wis., 53201.

Referring particularly to FIG. 1, system 10 includes fuel tank 14 that is mounted to lawn mower 12 via mounting assembly 15. In the preferred embodiment, fuel tank 14 includes hydrogen gas. Accordingly, for the purposes of the foregoing detailed description, hydrogen gas will be described.

A line 22 begins at fuel tank 14 and proceeds to back-flow valve 16. Back-flow valve 16 is a standard valve and is available from AirCo Gases Company, 575 Mountain Avenue, Murray Hill, N.J. 07974, part no. WCS CV-4M. PSI tank gauge 19 is inserted in line 22 between back-flow valve 16 and flow pressure gauge 18. PSI tank gauge 19 is available from AirCo Gases Company also, part no. WCS CV-5M, and serves as an indicator of fuel remaining in the tank 14. Flow pressure gauge 18 is used to monitor the flow of the hydrogen in pressure units. The flow is started using valve 16. The optimal flow pressure is 25 pounds of flow pressure from the tank 14 to the cylinder of the engine.

The flow of hydrogen is regulated via valve 20 that is part of gauge 18. Thus, when valve 20 is opened, hydrogen proceeds through line section 22 to hydrogen flow solenoid 26A. The user can access the hydrogen fuel by flipping hydrogen flow switch 24A into the "on" mode so that hydrogen gas in line 22 can proceed through hydrogen flow solenoid 26A and into line section 28.

Throttle 30 regulates the flow of hydrogen from line section 28 into line section 29 and ultimately, to engine 13. Throttle 30 is connected to throttle pedal 50 via includes throttle cable 48. Throttle pedal 50 also operates the butterfly valves in the carburetor in engine 13 in a conventional manner.

As an option, the throttle can be controlled electronically by a digital fuel controller product. Such a product is commercially available from Autotronic Controls Corp., 1490 Henry Brennan Drive, El Paso, Tex. 79936.

Line portion 29 proceeds through splitter 32 and is split into upper line 34 and lower line 36. Lines 34 and 36 proceed to adapters 38. Additional back-flow prevention valves 39 and 41 are mounted between lines 34 and 36 and adapters 38. Braided Teflon.RTM. is the preferred material for the fuel lines of the system.

Battery 42 is connected via battery cable 43 to magneto 44. Magneto 44 then controls the current through spark plug lines 46 to adapters 38 in a conventional manner. Thus, the regulation of the spark that ignites the fuel in the cylinder of engine 13 is conventional. Additionally, the intake of air into the engine 13 is accomplished through the standard carburetor system of engine 13. In a car, the sparking of the spark plugs can be controlled by the standard distributor/battery ignition system.

A second solenoid 26B controls the flow of gasoline from tank 23 through gasoline line 52. Solenoid 26B is controlled by switch 24B. Throttle 30 is connected to gasoline line 52 and can also be used to control the flow of gasoline to engine 13. Thus, this invention can be used with both an alternative fuel and gasoline.

Referring now to FIGS. 2, 3 and 4, the adapter 38 of this invention is shown in more detail. Adapter 38 includes housing 60. A threaded port 62 is formed into housing 60 through port block 64. Hydrogen lines are threadably connected to the adapter 38 via port 62. Port 62 is also referred to as an entrance port.

Adapter 38 also includes spark plug 66 which is effectively a standard spark plug except for the modification to the electrode as described below. Spark plug 66 includes a threaded end 68 which is threadably received in the threaded upper end 70 of housing 60. Spark plug wires 46 (as seen in FIG. 1) are connected to connector end 72 of spark plug base 66.

Electrode 76 protrudes from spark plug 66 and is of a length sufficient so that the threaded tip 77 (best seen in FIGS. 3 and 4) of the electrode 76 is proximate to the cylinder of the internal combustion engine when the adapter 38 is mounted. In one embodiment the electrode 76 is co-terminus with an exit port 88 of the adapter 38. This is most clearly shown in FIG. 4. Electrode 76 is preferably platinum to enhance catalysis of combustion by-products, as will be more fully discussed below.

Adapter 38 also includes plug 79. Plug 79 includes an axial internal void space 80. Thus, plug 79 fits over electrode 76 via internal void space 80. Plug 79 preferably comprises a ceramic material that acts as a good insulator. A suitable source for ceramic plug 79 is AM/PRO Machinery, Inc. 134 Church Street, Plain City, Ohio 43064-1321.

An important aspect of this invention is found on the external surface of plug 79. An annular groove 82 is formed on the surface of plug 79 near its distal end 81 so as to be proximal to the port 62 where hydrogen enters housing 60. Two stratifying grooves 84 proceed along the surface of plug 79 until they reach its distal end 83. It is these mixing structures, i.e. annual groove 82 and stratifying grooves 84, that facilitate the improved power generation from alternative fuels as provided by this invention. It will be apparent to those skilled in the analogous arts that the mixing structure may be formed on an inner surface 60i of the adapter housing 60. Alternatively, a combination of vortex producing structures may be attached to, and preferably integral with, both the plug 79 and the adapter housing inner surface 60i. Also, any conventional vortex producing means would be sufficient, i.e. grooves, per se, are not required. An entrance area 62a proximate the entrance port 62 is typically defined between the housing inner surface 60i and the external surface of plug 79. The external surface of plug 79 typically includes the grooves 84. So, the entrance area 62a is the volume of space within the housing, proximate the entrance port 62, which the gas will be able to occupy. This is most clearly shown in FIG. 4.

On threaded tip 77 of electrode 76, there are mounted a spacer nut 78 and a spark gap nut 85. As best seen in FIG. 2, the spark gap nut 85 includes a protrusion 85a that provides the spark gap between electrode 76 and periphery 89 of the exit port 88 of housing 60. The exit port 88 includes an exit area 88a. This is shown most clearly in FIGS. 2 and 4. The exit area 88a is no larger than the entrance area 62a. If the exit area 88a is smaller than the entrance area 62a, the pressure on the gas will increase. This increases the rate at which the gas is expelled from the plug 79, typically out through grooves 84. The electrode 76 is substantially co-terminus with the plug distal end 83 (seen most clearly in FIG. 2). Thus, the electrode 76 is substantially co-terminus with the exit port 88 or exit area 88a. Note that tip of the electrode 77 is preferably proximate with the exit area 88a because this is the location of greatest mixing. This is most clearly seen in FIG. 4. Preferably, the spark gap nut 85 is brass and the preferred spark gap distance is 25/1000 of an inch.

As best seen in FIG. 4, where arrows represent gas flow, hydrogen gas flows into chamber 60 via port 62. The hydrogen gas cools electrode 76, which facilitates combustion. Stratifying grooves 84, preferably there are two, act to mix the hydrogen that is flowing into housing 60 with ambient air therein. Though, more or less vortex creating grooves (a.k.a. stratifying grooves) may be desired. Typically, this will depend on the relative dimensions of the grooves and diameter of the plug as well as the pressure and velocity of the mixture in the housing. The mixing occurs within void space 86 of housing 60 and creates a vortexing or tornado action. Plug 79 tapers as it proceeds from its distal end 81 to its proximal end 83. Thus, proximal end 83 is smaller in diameter than distal end 81. This provides additional space within void space 86 for the mixing of the hydrogen and air. The stratified hydrogen/air are twisting in a vortex fashion when leaving housing 60 via exit port 88. The vortexing action produced by grooves 84 on the plug 79 creates a "tornado" 110 of hydrogen/air with a hollow center that generates a vacuum. Similar effect, or vortex flow path, would result were the grooves to be placed on the housing. The vacuum propels the hydrogen/air mixture into the cylinder of the engine for combustion. Such mixing cannot be accomplished in a conventional induction system.

Referring now to FIG. 5, a schematic of the system of this invention is portrayed, with arrows representing gas flow. Hydrogen flows in through port 62 through adapter 38 and into cylinder 92. Air enters cylinder 92 through air intake 90 and air intake valve 91. The stratified hydrogen/air mixture is compressed in the compression stroke of the engine via piston 94 and push rod 96, which are standard structures in an internal combustion engine. In the power stroke shown in FIG. 5-C, a spark is generated in the compressed stratified hydrogen/air mixture ignites and drives piston 94 and push rod 96 to power the engine.

The mass energy density of hydrogen is enhanced through the increased pressure on the hydrogen exerted by piston 94 on the hydrogen/air mixture within the cylinder 92 in the uptake stroke in an internal combustion engine. The pressurized and well-mixed hydrogen/air mixture is rapidly ignited through the spark because hydrogen has a fast flame front. This reduces problems with timing. Thus, the energy store found in hydrogen is captured through this system via the compression of the hydrogen gas within cylinder 92 and via the thorough mixing of hydrogen and air provided by adapter 38.

In addition, in the exhaust phase in a four cycle engine a second spark is generated from the plug to ensure complete combustion of by-products. This is enhanced by using an electrode made of platinum. Exhaust leaves cylinder 92 through exhaust port 98. Exhaust port 98 is closed during other phases by exhaust outlet valve 100.

In the exhaust stroke, because air valve 91 is closed, the substantial component of the gases in cylinder 92 is hydrogen. This is also accomplished due to the fact that in the system of this invention, the hydrogen is continuously flowing. When this spark interacts with what is predominately hydrogen, a plasma is formed. This plasma blocks back-flow of air from exhaust port 98. Prevention of back-flow of air prevents the hydrogen fuel system from backfiring, which is another common problem of hydrogen fuel systems. In effect, then, the plasma formed by the hydrogen acts as a virtual valve in that the plasma blocks the back-flow of air.

When the plasma of the hydrogen is generated as described above, UV radiation is generated which also facilitates consumption of combustion by-products. This increases the environmental friendliness of the system.

In addition to hydrogen the following fuels can be used in this system: natural gas; alcohol; gasohol; propane and buthane. A mixture of hydrogen and natural gas can also be used. As noted above, gasoline can be used in this system when solenoid 26 is used to stop the flow of hydrogen.

Further, it is contemplated that an adapter that is described herein for use with an internal combustion engine can also be used with a home heating system such as a home heating system that may currently use natural gas. The vortexing action created by the plug would enable appropriate power to be captured from the hydrogen fuel so as to effectively heat a home.

Thus, the apparatus and system of this invention provides an effective means to use alternative fuels. The use of alternative fuels can enhance the environment by reducing the use of conventional gasoline and the environmentally detrimental by-products caused by the consumption thereof.

Thus, although there have been described particular embodiments of the present invention of a new and useful "Fuel System For Internal Combustion System And Adapter For Use In Same", it is not intended that such references be construed as limitations upon the scope of this invention except as set forth in the following claims. Further, although there have been described certain dimensions used in the preferred embodiment, it is not intended that such dimensions be construed as limitations upon the scope of this invention except as set forth in the following claims.

United States Patent 6,119,651

September 19, 2000

Hydrogen Powered Vehicle, Internal Combustion Engine, and Spark Plug for use in same

Abstract --- The internal combustion engine fuel system described includes a structure for mixing the alternative fuel, preferably hydrogen, with oxygen in ambient air to stratify the fuel. The system includes an adapter, and the adapter includes a housing mounted between spark plug and cylinder of the internal combustion engine. A plug is placed within the housing. The plug has ridges or grooves on its outer surface that act as mixing structures. Thus, when hydrogen is introduced into the adapter housing it is mixed with ambient oxygen within the chamber as it flows over the plug. The mixing structures in the housing creates a vortexing action as the hydrogen flows over the plug

and towards the cylinder of the engine. An electrode protrudes from the plug towards the cylinder. The electrode is preferably platinum and generates the necessary spark to create combustion of the hydrogen/air mixture adjacent to the cylinder to thereby power the cylinder in the engine. A platinum electrode is preferably used because it enhances a catalytic conversion of combustion by-products to more environmentally compatible products. The present invention also teaches a spark plug producing a hotter spark for a hydrogen fuel system. Also taught is a hydrogen powered vehicle with reduced emissions by producing a spark during the power stroke and the exhaust stroke. Methods for reducing exhaust pollution are also taught. Methods of reducing exhaust pollution by generating a plasma are taught as well.

Description

BACKGROUND OF THE INVENTION

The present invention relates generally to a fuel system for internal combustion engines that enables the invention to utilize alternative fuels; and, more particularly to an improved fuel system for an internal combustion engine and an adapter and spark plug for use in same.

The problems of air pollution caused by automobiles, lawn mowers and other vehicles that have internal combustion engines powered by gasoline is well documented. This problem is particularly described in an article in the San Diego Union Tribune, Wednesday, Sep. 25, 1996 and in Popular Science, August 1996. Indeed, under the Clean Air Act, in the next few years cars that do not run on standard fossil fuels like gasoline will be required in several states. Currently, there are no vehicles available to meet this need.

Thus, it will be appreciated by those skilled in the art that there has been a push to seek other fuels for use in internal combustion engines. These fuels include methane, propane and gasohol.

Hydrogen has also been characterized as a promising fuel source. See Department of Energy publication entitled "Hydrogen Fuel", printed in 1978, U.S. Government Printing Office, U.S. Department of Energy, Office of Public Affairs, Washington, DC 20585. Particularly, the graph presented in FIG. 6, which is copied from this publication, shows the potential for hydrogen in BTUs/Lb. However, the mass energy density for hydrogen is low; and thus, hydrogen needs to be compressed before its energy potential can be realized. Hydrogen is a "dry fuel" that is more difficult to ignite than "wet fuels." It becomes more difficult to ignite when it is cooled. However, cooling is preferred in most systems to avoid premature ignition of the fuel. Other systems deliver the hydrogen under pressure to prevent ignition in the supply line, which is a form of pre-ignition. No prior art fuel system has been able to capture the energy of hydrogen.

Several fuel systems for use with hydrogen have been proposed. Examples are described in U.S. Pat. Nos. 4,167,919; 4,253,428; 4,016,836; 4,178,882; 5,222,993; 5,085,176; and 5,085,176. The problem with these prior art fuel systems is they cannot take advantage of the alternative fuels to generate sufficient power from the fuels to drive an internal combustion engine for use in a lawn mower, automobile or other vehicle. As noted above, this is a particular problem when hydrogen is used as a fuel. Additionally, the prior art systems do not address the problem of back fire, i.e. undesired explosion of the fuel in the cylinder during the exhaust stroke of the internal combustion engine.

Premature ignition or backfire is often a problem with hydrogen fueled systems. U.S. Pat. No. 4,383,198 (Hosking) teaches a fuel injection spark plug with a pre-cooling chamber to avoid premature ignition indentination of a gaseous fuel supplied to the spark plug. U.S. Pat. No. 4,383,198, Hosking, entitled "Fuel Injection Spark Plug", issued May 10, 1983, is hereby incorporated herein by reference. However, cooling hydrogen makes it more difficult to ignite. This is because hydrogen is a dry fuel whereas gas is generally considered a wet fuel. Thus to reduce fuel pollution one prefers to utilize a fuel such as hydrogen and ignite it with a hotter spark.

One patent discussing very high energy (VHE) ignition systems is U.S. Pat. No. 5,207,208 issued to Ward, entitled "Integrated Convertor High Power CD Ignition", issued May 4, 1993. U.S. Pat. No. 5,207,208 is hereby incorporated herein by reference. Pat. '208 teaches very high energy ignition systems, for instance on the order of 36K volts. It teaches voltage doubling utilizing pulsating sparks of peak current on the order of two amps. While 36K volts may at times be adequate, it is preferable to achieve a higher voltage in the ignition chamber when using hydrogen.

It is known in the art to use a direct ignition system, also referred to as a distributorless ignition system, to increase the spark plug voltage. Such direct ignition systems use a "waste spark" method of spark distribution. Each cylinder is paired with its opposing cylinder in the firing order (1-4, 2-3, on a four cylinder, 1-4, 2-5, 3-6 on a V6) so that one cylinder on compression fires simultaneously with its opposing cylinder on exhaust stroke. Since the cylinder on exhaust stroke requires very little of the available voltage to fire its plug, most of the voltage is used to fire the cylinder on the compression stroke.

U.S. Pat. No. 4,462,380 discusses a distributorless ignition system. U.S. Pat. No. 4,462,380 entitled "Enhanced Spark Energy Distributorless Ignition System" issued Jul. 31, 1984 by Asik is hereby incorporated herein by reference. Pat. '380 teaches a distributorless ignition system of an internal combustion engine which has a supplementary spark energy module to increase spark energy. Each high voltage terminal is connected to a single spark plug and each ignition coil primary is alternately energized and quickly de-energized, producing opposite polarity ignition voltages at each coil terminal. As a result, pairs of spark plugs are alternately fired, with each firing pair occurring in a compression or exhaust stroke and thereby providing the proper ignition to the engine. Asik asserts that firing a spark plug does not affect engine performance or emissions. As taught by the instant invention this is incorrect for hydrogen fuels when the exhaust is sparked at a sufficient voltage.

U.S. Pat. No. 5,146,882 (Brinkman) teaches use of specific wet fuel mixtures in conjunction with direct ignition systems (D.I.S.). It teaches that technical breakdown voltages for typical spark plugs are on the order of 15-20 kV and DIS typically yield between 30 kV-40 kV. U.S. Pat. No. 5,146,882, entitled "Method And Apparatus For Cold Starting A Spark Ignited Internal Combustion Engine Fueled With An Alcohol-Based Fuel Mixture", by Brinkman, et al., issued Sep. 15, 1992, is hereby incorporated herein by reference. The previously referenced prior art discusses alternate fuels and fuel systems but does not teach a method of achieving a sufficient voltage with a hydrogen system.

What is needed, then, is a fuel system for an internal combustion engine that provides a way to generate sufficient power from the alternative fuels and that reduces backfire problems. Such a system is lacking in the prior art. Also lacking in prior art is a system utilizing alternate fuels with reduced pollution capabilities. Also lacking is a way of generating sufficient voltage spark to ignite the alternate fuel.

The following U.S. Patents discuss spark plugs designed for gas internal combustion engines to reduce radio frequency noise and interference. U.S. Pat. No. 4,224,554, entitled "Spark Plug Having A Low Noise Lever" issued to Nishio et al., Sep. 23, 1980 is hereby incorporated herein by reference. U.S. Pat. No. 4,029,990 entitled "Spark Plug Construction" issued to Nagy et al., Jun. 14, 1977 is hereby incorporated herein by reference.

SUMMARY OF THE INVENTION

It is an object of this invention to provide an improved fuel system for use with alternative fuels.

It is a further object of this invention to provide an improved fuel system for use particularly with hydrogen, and particularly to enhance the mass energy density of hydrogen.

It is an object to provide a hotter sparking plug to ignite the fuel.

It is still a further object of this invention to provide an adapter for use in a fuel system for an internal combustion engine that enhances the power obtained from the alternative fuels.

It is still a further object of this invention to provide an improved fuel system for an internal combustion engine that does not present the environmental hazards of a standard gasoline engine by providing reduced or zero emission of environmentally harmful gases.

It is yet a further object of this invention to provide an improved fuel system for an internal combustion engine that can use an alternative fuel and can use gasoline to facilitate the transition from gasoline to alternative fuels.

It is yet a further object of this invention to provide an improved fuel system for an internal combustion engine that reduces backfire problems.

It is yet a further object of this invention to provide an improved fuel system for an internal combustion engine that reduces backfire problems by cooling the electrode in the spark plug with the hydrogen gas fuel.

It is an object to reduce backfire by providing hydrogen at a sufficient pressure to reduce backfire and igniting it with a hotter spark (i.e. a higher voltage).

It is still a further object of this invention to provide an adapter for use in a fuel system for an internal combustion engine that enhances the power obtained from the alternative fuels.

It is a further object to generate a plasma field in a cylinder to burn residual exhaust and reduce emissions.

It is yet a further object of this invention to provide a direct injection fuel system wherein fuel is injected directly into the cylinder.

It is an object to provide a "2-fire" direct injection system, wherein the fuel is ignited during the power stroke and the exhaust stroke.

It is yet a further object of this invention to provide a way to convert the standard induction fuel system of a lawnmower to a direct injection fuel system wherein fuel is injected directly into the cylinder.

It is yet a further object of this invention to provide a way to convert the indirect injection fuel system of an automobile to a direct injection fuel system wherein fuel is injected directly into the cylinder.

The internal combustion engine fuel system of this invention includes a structure for mixing the alternative fuel, preferably hydrogen, with oxygen in ambient air to stratify the fuel. The term "alternative fuels" is known in the art and is meant to refer to fuels other than conventional gasoline.

The invention in one embodiment comprises an adapter, the adapter including a housing mounted between spark plug and cylinder of the internal combustion engine. A plug is placed within the housing. The plug has ridges or grooves on its outer surface that act as mixing structures. Thus, when hydrogen is introduced into the adapter housing it is mixed with ambient oxygen within the chamber as it flows over the plug. The mixing structures on the plug create a vortexing action as the hydrogen flows over the plug and towards the cylinder of the engine.

An electrode protrudes from the plug towards the cylinder. The electrode is preferably platinum and generates the necessary spark to create combustion of the hydrogen/air mixture adjacent to the cylinder to thereby power the cylinder in the engine. A platinum electrode is preferably used because it enhances a catalytic conversion of combustion by-products to more environmentally compatible products.

Thus, the combination of the compression action generated by the conventional piston and push rod within the cylinder of the engine in conjunction with the hydrogen/air mixing structure that vortexes the hydrogen/air create compressed hydrogen that is mixed with a combustion facilitator, i.e. oxygen in the ambient air to enable the system of this invention to capture the abundant energy found in hydrogen fuel.

The enhanced mixing capabilities of this invention is also adaptable for use with other alternative fuels such as natural gas, alcohol, propane and the like.

One embodiment of the present invention is for a hydrogen powered vehicle including an internal combustion engine operably connected to power the vehicle and adapted to connect to a hydrogen supply line. The internal combustion engine comprises a cylinder operably connected to the supply line; a piston operably disposed in the cylinder; and a spark plug having an electrode assembly in operable sparking communication with the cylinder, wherein the spark plug is capable of producing a spark of at least 45 kV.

Preferably the spark plug comprises a housing having a sparking end and a hollow chamber containing the electrode assembly. The electrode assembly comprises an electrode having a connector end and a sparking end, wherein the sparking end is positioned adjacent to the housing sparking end. The electrode assembly preferably comprises a coil electrically connected to the electrode connector.

Preferably the housing comprises a fuel inlet port in fluid communication with the supply line, and an insulator surrounding the electrode assembly, wherein the insulator is positioned in the hollow chamber. Preferably the insulator comprises an outer surface defining a first fuel channel having a first respective fuel exit port, wherein the first fuel channel is in fluid communication with the fuel inlet port and the fuel exit port exits into the cylinder.

The present invention also includes a method of operating an internal combustion engine comprising supplying hydrogen fuel to the engine and creating a spark in the cylinder during the power stroke and the exhaust stroke, wherein the spark created during the power stroke is at least 45 kV. In one embodiment the spark is at least 70 kV. In certain embodiments the method comprises generating plasma during the exhaust stroke. The exhaust fuel converts to an exhaust emission and coalesces with the plasma, thereby reducing fuel pollution.

Accordingly, it is an object in the invention to provide a spark plug producing a sufficiently hot spark to ignite hydrogen fuel, including cooled hydrogen fuel.

Another object of the present invention is to provide a device for reducing fuel exhaust emissions.

Another object of the present invention is to provide a cleaner burning engine.

Another object is to provide a spark plug for reducing emissions.

Another object of the present invention is to provide a device functional with dry fuels. Use of the term hydrogen, as discussed herein, is intended to encompass such dry fuels. However the term as used excludes such wet fuels as gas and alcohol.

Another object of the present invention is to provide an integrated fuel system adapted to provide these and objectives.

Other objects and advantages of the present invention will be apparent to those of skill in the art by reference to the teachings disclosed herein, including the attached drawings, detailed description of exemplary embodiments, and claims.

DESCRIPTION OF THE PREFERRED EMBODIMENT

Referring now to the drawings, wherein like reference numerals refer to like parts throughout, the fuel system is referred to generally at 10. The fuel system of this invention is contemplated for use with an internal combustion power system, such as an internal combustion engine or such as a home heating system. Fuel system 10 is portrayed in this case as connected to a standard lawn mower. The lawn mower is shown in phantom at 12 in FIG. 1. The lawn mower is a conventional lawn mower as can be purchased from a company such as Murray of Ohio. The internal combustion engine in the lawn mower is a standard 4-cycle engine with two cylinders and develops 18 horsepower. A suitable example can be purchased from Briggs & Stratton, Milwaukee, Wis. 53201.

Referring particularly to FIG. 1, system 10 includes fuel tank 14 that is mounted to lawn mower 12 via mounting assembly 15. In the preferred embodiment, fuel tank 14 includes hydrogen gas. Accordingly, for the purposes of the foregoing detailed description, hydrogen gas will be described.

A line 22 begins at fuel tank 14 and proceeds to back-flow valve 16. Back-flow valve 16 is a standard valve and is available from AirCo Gases Company, 575 Mountain Avenue, Murray Hill, N.J. 07974, part no. WCS CV-4M. PSI tank gauge 19 is inserted in line 22 between back-flow valve 16 and flow pressure gauge 18. PSI tank gauge 19 is available from AirCo Gases Company also, part no. WCS CV5M, and serves as an indicator of fuel remaining in the tank 14. Flow pressure gauge 18 is used to monitor the flow of the hydrogen in pressure units. The flow is started using valve 16. The optimal flow pressure is 25 pounds of flow pressure from the tank 14 to the cylinder of the engine.

The flow of hydrogen is regulated via valve 20 that is part of gauge 18. Thus, when valve 20 is opened, hydrogen proceeds through line section 22 to hydrogen flow solenoid 26A. The user can access the hydrogen fuel by flipping hydrogen flow switch 24A into the "on" mode so that hydrogen gas in line 22 can proceed through hydrogen flow solenoid 26A and into line section 28.

Throttle 30 regulates the flow of hydrogen from line section 28 into line section 29 and ultimately, to engine 13. Throttle 30 is connected to throttle pedal 50 via includes throttle cable 48. Throttle pedal 50 also operates the butterfly valves in the carburetor in engine 13 in a conventional manner.

As an option, the throttle can be controlled electronically by a digital

fuel controller product. Such a product is commercially available from Autotronic Controls Corp., 1490 Henry Brennan Drive, El Paso, Tex. 79936.

Line portion 29 proceeds through splitter 32 and is split into upper line 34 and lower line 36. Lines 34 and 36 proceed to adapters 38. Additional back-flow prevention valves 39 and 41 are mounted between lines 34 and 36 and adapters 38. Braided Teflon.RTM. is the preferred material for the fuel lines of the system.

Battery 42 is connected via battery cable 43 to magneto 44. Magneto 44 then controls the current through spark plug lines 46 to adapters 38 in a conventional manner. Thus, the regulation of the spark that ignites the fuel in the cylinder of engine 13 is conventional. Additionally, the intake of air into the engine 13 is accomplished through the standard carburetor system of engine 13. In a car, the sparking of the spark plugs can be controlled by the standard distributor/battery ignition system.

A second solenoid 26B controls the flow of gasoline from tank 23 through gasoline line 52. Solenoid 26B is controlled by switch 24B. Throttle 30 is connected to gasoline line 52 and can also be used to control the flow of gasoline to engine 13. Thus, this invention can be used with both an alternative fuel and gasoline.

Referring now to FIGS. 2, 3 and 4, the adapter 38 of this invention is shown in more detail. Adapter 38 includes housing 60. A threaded port 62 is formed into housing 60 through port block 64. Hydrogen lines are threadably connected to the adapter 38 via port 62. Port 62 is also referred to as an entrance port. The entrance port has an entrance area 62a.

Adapter 38 also includes spark plug 66 which is effectively a standard spark plug except for the modification to the electrode as described below. Spark plug 66 includes a threaded end 68 which is threadably received in the threaded upper end 70 of housing 60. Spark plug wires 46 (as seen in FIG. 1) are connected to connector end 72 of spark plug base 66.

Electrode 76 protrudes from spark plug 66 and is of a length sufficient so that the threaded tip 77 (best seen in FIGS. 3 and 4) of the electrode 76 is proximate to the cylinder of the internal combustion engine when the adapter 38 is mounted. In one embodiment the electrode 76 is coterminus with an exit port 88 of the adapter 38. This most clearly is shown in FIG. 4. Electrode 76 is preferably platinum to enhance catalysis of combustion by-products, as will be more fully discussed below.

Adapter 38 also includes plug 79. Plug 79 includes an axial internal void space 80. Thus, plug 79 fits over electrode 76 via internal void space 80. Plug 79 preferably comprises a ceramic material that acts as a good insulator. A suitable source for ceramic plug 79 is AM/PRO Machinery, Inc. 134 Church Street, Plain City, Ohio 43064-1321.

An important aspect of this invention is found on the external surface of plug 79. An annular groove 82 is formed on the surface of plug 79 near its distal end 81 so as to be proximal to the port 62 where hydrogen enters housing 60. Two stratifying grooves 84 proceed along the surface of plug 79 until they reach its distal end 83. It is these mixing structures, i.e. annual groove 82 and stratifying grooves 84, that facilitate the improved power generation from alternative fuels as provided by this invention. It will be apparent to those skilled in the analogous arts that mixing structure may be formed in the inner surface of the adapter housing 60.

Alternatively a combination of vortex producing structures is integral with both the plug 79 and adapter housing 60. Also any conventional vortex producing means should be sufficient groves, per se, are not required.

On threaded tip 77 of electrode 76, there are mounted a spacer nut 78 and a spark gap nut 85. As best seen in FIG. 2, the spark gap nut 85 includes a protrusion 85a that provides the spark gap between electrode 76 and periphery 89 of the exit port 88 of housing 60. The exit port 88 includes an exit area 88a. Preferably, the exit area 88a is no larger than the entrance area 62a, though this is not critical. Preferably, the spark gap nut 85 is brass and the preferred spark gap distance is 25/1000 of an inch. Of course, the electrode may be coterminus with the plug distal end 83.

As best seen in FIG. 4, where arrows represent gas flow, hydrogen gas flows into chamber 60 via port 62. The hydrogen gas cools electrode 76, which facilitates combustion. Stratifying grooves 84, preferably there are two, act to mix the hydrogen that is flowing into housing 60 with ambient air therein. Though more or less vortex creating grooves (stratifying grooves) may be desired. Typically this will depend on the relative dimensions of the grooves and diameter of the plug as well as the pressure or velocity of the mixture in the housing. The mixing occurs within void space 86 of housing 60 and creates a vortexing or tornado action. Plug 79 tapers as it proceeds from its distal end 81 to its proximal end 83. Thus, proximal end 83 is smaller in diameter than distal end 81. This provides additional space within void space 86 for the mixing of the hydrogen and air. The stratified hydrogen/air are twisting in a vortex fashion when leaving housing 60 via exit port 88. The vortexing action produced by grooves 84 on the plug 79 creates a "tornado" 110 of hydrogen/air with a hollow center that generates a vacuum. Similar effect would result were t he grooves to be placed on the housing. The vacuum propels the hydrogen/air mixture into the cylinder of the engine for combustion. Such mixing cannot be accomplished in a conventional induction system.

Referring now to FIG. 5, a schematic of the system of this invention is portrayed, with arrows representing gas flow. Hydrogen flows in through port 62 through adapter 38 and into cylinder 92. Air enters cylinder 92 through air intake 90 and air intake valve 91. The stratified hydrogen/air mixture is compressed in the compression stroke of the engine via piston 94 and push rod 96, which are standard structures in an internal combustion engine. In the power stroke shown in FIG. 5-C, a spark is generated in the compressed stratified hydrogen/air mixture ignites and drives piston 94 and push rod 96 to power the engine.

The mass energy density of hydrogen is enhanced through the increased pressure on the hydrogen exerted by piston 94 on the hydrogen/air mixture within the cylinder 92 in the uptake stroke in an internal combustion engine. The pressurized and well-mixed hydrogen/air mixture is rapidly ignited through the spark because hydrogen has a fast flame front. This reduces problems with timing. Thus, the energy store found in hydrogen is captured through this system via the compression of the hydrogen gas within cylinder 92 and via the thorough mixing of hydrogen and air provided by adapter 38.

In addition, in the exhaust phase in a four cycle engine a second spark is generated from the plug to ensure complete combustion of by-products. This is enhanced by using an electrode made of platinum. Exhaust leaves cylinder 92 through exhaust port 98. Exhaust port 98 is closed during other phases by exhaust outlet valve 100.

In the exhaust stroke, because air valve 91 is closed, the substantial component of the gases in cylinder 92 is hydrogen. This is also accomplished due to the fact that in the system of this invention, the hydrogen is continuously flowing. When this spark interacts with what is predominately hydrogen, a plasma is formed. This plasma blocks back-flow of air from exhaust port 98. Prevention of back-flow of air prevents the hydrogen fuel system from backfiring, which is another common problem of hydrogen fuel systems. In effect, then, the plasma formed by the hydrogen acts as a virtual valve in that the plasma blocks the back-flow of air.

When the plasma of the hydrogen is generated as described above, UV radiation is generated which also facilitates consumption of combustion by-products. This increases the environmental friendliness of the system.

In addition to hydrogen the following fuels can be used in this system: natural gas; alcohol; gasohol; propane and buthane. A mixture of hydrogen and natural gas can also be used. As noted above, gasoline can be used in this system when solenoid 26 is used to stop the flow of hydrogen.

Further, it is contemplated that an adapter that is described herein for use with an internal combustion engine can also be used with a home heating system such as a home heating system that may currently use natural gas. The vortexing action created by the plug would enable appropriate power to be captured from the hydrogen fuel so as to effectively heat a home.

Another embodiment of the invention is a hydrogen powered vehicle 200 shown in FIG. 7. The hydrogen powered vehicle 200 includes an internal combustion engine 210 operably connected to power the vehicle 200 and adapted to connect to a hydrogen supply 212 through a supply line 214.

Referring to FIG. 8, the internal combustion engine 210 comprises a cylinder 92 operably connected to the supply line 214. A piston 94 is operably disposed in the cylinder 92. A spark plug 216 having an electrode assembly 218 (not shown in FIG. 8) is in operable sparking communication with the cylinder 92, wherein the spark plug 216 is capable of producing a spark 220 (shown in FIG. 10) of at least 45 kilovolts. FIGS. 8-11 are substantially similar to FIGS. 5A-5D depicting schematic representations of a 4-cycle piston-cylinder engine. Other piston and cylinder embodiments will be apparent to those with skill in the art. FIG. 8 represents an intake stroke. FIG. 9 depicts a compression stroke. FIG. 10 depicts a power stroke, in which the spark plug 216 sparks. FIG. 11 depicts an exhaust stroke, where the spark plug 216 is sparking. Refer to FIGS. 5A-5D discussed earlier for further description of similar components of FIGS. 8-11.

FIG. 12 shows one embodiment of the spark plug 216 in an elevated side view. FIG. 13 shows a plan view of the spark plug 216 along line 13--13 shown in FIG. 12. FIG. 14 shows a plan view of the spark plug 216 in the direction of line 14--14 shown in FIG. 12.

FIG. 15 depicts a section view of the spark plug 216. FIG. 15, section view, depicts a representative spark plug 216. The spark plug shown in FIG. 15 comprises a housing 222 having a sparking end 224 and a hollow chamber 226 containing the electrode assembly 218.

FIG. 16 depicts the electrode assembly 218 removed from the hollow chamber 226. The electrode assembly 218 depicted in FIG. 16 comprises an electrode 228. The electrode 228 has a connector end 230 and a sparking end 232. As shown in FIG. 15 the sparking end 232 of the electrode 228 is positioned adjacent to the housing sparking end 224. The electrode assembly further comprises a coil 234 electrically connected to the electrode connector end 230.

Referring to FIGS. 10 and 11, wherein the piston 94 moves through a power stroke in FIG. 10 and an exhaust stroke in FIG. 11, the spark plug 216 is shown to fire during the power stroke and the exhaust stroke.

The electrode assembly 218 shown in FIG. 16 comprises a steel ball 236 positioned between the coil 234 and the electrode connector end 230. Other operable ball-coil-electrode arrangements will be apparent to those of skill in the art.

The spark plug 216 shown in FIG. 15 also comprises an insulator 238 surrounding the electrode assembly 218 and positioned in the hollow chamber 226. A ceramic pore 240 is shown stabilizing the insulator 238 in the hollow chamber 226. Other methods of locating the insulator in the hollow chamber will be apparent to those of skill in the art.

An elevated section view of the housing 222 is shown in FIG. 17. An elevated side view of the housing 222 is shown in FIG. 18. In the exemplary embodiment of the housing 222 shown in FIG. 18, the housing 222 comprises a fuel inlet port 242 in fluid communication with the supply line 214 (not shown). FIG. 19 depicts an exemplary embodiment of the insulator 238. The insulator 238, shown in FIG. 19, comprises an outer surface 244 defining a first fuel channel 246 having a first respective fuel exit port 248. The first fuel channel 246 is in fluid communication with the fuel inlet port 242. The fuel exit port 248 exits into the cylinder 292.

FIG. 20 shows a plan view of the insulator 228 shown in FIG. 19 along line 20--20. FIG. 21

shows a section view of the insulator 228 shown in FIG. 19 viewed along section line 21--21. FIG. 22 depicts a bottom plan view of the insulator 228 shown in FIG. 19 along line 22--22. FIG. 23 shows a section view of the insulator 228 cut through section line 23--23 shown in FIG. 19.

In the embodiment of the insulator 228 shown in FIGS. 19-22, the insulator outer surface 244 defines a plurality of fuel channels 250, including the first fuel channel 246. The fuel channels 250 include a plurality of respective fuel exit ports 252, including the first fuel exit port 248. This is shown clearly in FIG. 22. Preferably, the plurality of fuel channel exit ports 252 are spaced equally, or equi-distant, about the electrode 228. This is shown well in FIGS. 21 and 22.

Referring to FIGS. 15 and 17, one embodiment of the housing 222 sparking and 224 comprises a torridal ground electrode 254 positioned about the electrode sparking end 232 (shown in FIG. 15). Preferably the housing sparking end 224 and the electrode sparking end 232 are co-terminous. In one embodiment the first respective fuel exit port 248 is co-terminous with the housing sparking end 224 and the electrode sparking end 232.

More generally the present invention includes an internal combustion engine 210 adapted to operate on hydrogen fuel supplied through a supply line 214. Typically the engine comprises a first cylinder 92 in fluid communication with the supply line 214; a first piston 94 disposed in the first cylinder 92 to move through a power stroke and an exhaust stroke (See FIGS. 10 and 11) in the first cylinder 92. The engine 210 also comprises a spark plug 216 having a housing 222 including a sparking end 224 and an electrode assembly 218 located in the housing 222, wherein the sparking end 224 is in operable communication with the cylinder 92 and capable of producing a spark 220 of at least 45 kV. Preferably, the spark plug 216 fires during the power stroke and the exhaust stroke. In one embodiment the housing sparking end 224 comprises a torridal ground electrode 254. The electrode assembly 218 comprises an electrode 228 having a sparking end 230 capable of sparking toward the torridal ground electrode 254. Preferably the electrode assembly 218 comprises a coil 234 in electrical communication with the electrode 228.

In one embodiment the electrode assembly 218 comprises an electrode 228 having a sparking end 230 and a coil 234 electrically connected to the electrode 228 opposite the electrode sparking end 230. This is the embodiment shown in FIG. 15. Typically the spark plug 216 comprises an insulator 228 surrounding the electrode assembly 218. Preferably the insulator 228 includes a fuel channel 246 having a fuel exit port 248 near the electrode sparking end 232.

It will be apparent to those with skill in the art that the present invention also comprises a method of operating an internal combustion engine 210 comprising the steps of supplying hydrogen fuel to the engine 210; moving a piston 94 in a cylinder 92 through a power stroke and an exhaust stroke; creating a spark 220 in the cylinder 92 during the power stroke and the exhaust stroke, wherein the spark created during the power stroke is at least 45 kV; and supplying the fuel to a location sufficiently near the spark to ignite the fuel. This is shown well in FIGS. 10, 15 and 19.

The present invention also includes a method wherein the step of creating a spark 220 comprises passing an electric current (not shown) through an electrode assembly 218 including a coil 234 electrically connected to an electrode 218 having a sparking end 232; insulating the electrode assembly 218; and arcing the electric current from the electrode sparking end 232 to a ground electrode 254. The ground electrode 254 as shown in FIGS. 15 and 17 a toroidal ground electrode 254.

In certain embodiments the step of creating a spark 220 includes creating a spark 220 having at least 70 kV. Creating a spark of sufficient voltage will generally reduce the exhaust pollution. Typically this happens by generating a plasma or plasma field during the exhaust stroke. Thus, one method of the present invention further comprises the steps of generating plasma during the exhaust stroke; and allowing exhaust fuel converted to an exhaust state to coalesce with the plasma. This reduces exhaust pollution.

Thus, the apparatus and system of this invention provides an effective means to use alternative fuels. The use of alternative fuels can enhance

the environment by reducing the use of conventional gasoline and the environmentally detrimental by-products caused by the consumption thereof.

Thus, although there have been described particular embodiments of the present invention of a new and useful "Hydrogen Powered Vehicle, Internal Combustion Engine, And Spark Plug For Use In Same", it is not intended that such references be construed as limitations upon the scope of this invention except as set forth in the following claims. Further, although there have been described certain dimensions used in the preferred embodiment, it is not intended that such dimensions be construed as limitations upon the scope of this invention except as set forth in the following claims.

Herman P. ANDERSON
(1918-2004)

Herman P. Anderson Technologies, LLC
PO Box 2014
Brentwood, TN 37024-2014

Herman and his water-powered Chevy Cavalier.

by James Allen

He could drive it, but he was not allowed to sell any, or manufacture his discovery in the State of Tennessee. Why not?

Herman's special patented sparkplugs, similar to Stan Meyer's plugs.

Herman has consulted with Nasa and the US Airforce on some of our country's most important Top Secret Projects including the first US satellite in space, the SR-71 Blackbird, the Stealth Fighter/Bomber and Starwars. Herman worked closely with Dr. Wernher von Braun testing hydrogen powered rocket engines, and he also worked with engineers at the now famous Skunk Works, the Jet Propulsion Laboratory, JPL, and Cal Tech. While in the Air Force during WWII, Herman served as a fighter pilot, a flight instructor and bombardier trainer. He was certified in and flew 23 different airplanes during this period.

Herman believed in a Hydrogen Future and FREE fuel!

Herman's 1971 Ford LTD converted to run on hydrogen or gasoline, on display in the Water Fuel Museum in Lexington, KY. In a video interview with the inventor, he explains that ambient air is mixed with hydrogen (not oxygen) and a micron-sized fog of water mist (to mimic gasoline's burn), introduced in the same way propane gas is on a propane conversion. In fact, the LP regulator and LP aircleaner assembly are the same as on a propane vehicle. The butterfly in the carb, as in an LP system, now serves as the intake air control. The rest of the function of the gasoline carb is not used. He claimed greater power than gasoline, and 38 miles per gallon of water. As far as quantity of hydrogen produced, he produced enough gas from his electrolytic chamber to need a cut-off switch connected to a pressure gauge to stop gas production when it was no longer needed while driving. In other words, instead of producing more or less gas on demand, as some systems do, it appears his system always produced the same amount, but was turned on and off as needed. He emphasized that deuterium (heavy water) was essential to his approach, doubling the density of the hydrogen, making it twice as powerful. He also used high voltage, 70,000 volts to be exact, from two custom-made coils, to effect rapid separation of the component gases, a process which he calls 'radiolysis.' The 70,000 volts constitute what he calls a 'soft' x-ray, not radioactive but in need of shielding, in-between a microwave oven and a 'hard' x-ray. He was authorized by the state of Tennessee to drive his car as they recognized that he knew what he was doing with such technology. I view his prototype LTD as good proof of a watercar for those who doubt that the technology is even possible, but not necessarily the best approach for you and me to pursue. He accomplished his invention along the lines of his expertise, the field of ionics; others have approached it differently with less controversial technology and have been equally successful.

My thoughts about Herman

Herman's 1978 Fort LTD came to be known as The Green Machine. Using a modified propane carburetor, Herman converted the LTD to run on hydrogen in 1980. Due to the low mass energy density of hydrogen, Herman was only able to get a little more than half power from the engine with this traditional induction system.

Because Herman only used a single cell, I believe you need to do the 3 cells hooked up in series like Archie Blue, Dingel's and Peter's design. Use - 3 - 4"dia. SS tubes , 8" long (cells) welded together. Put your series of SS plates inside each cell. gas lines coming out the top through a check value to the bottom of the next cell. Use rubber caps ends with hose clamps so if it ever blows it just blows the caps off and the water is drained and your mild explosion is over with.

You need more molecules of hydrogen clustered together as they pass thru 3 cells then into the IMPCO propane fuel injection carburetor. In gasoline SAE words a higher octane of hydrogen (ortho hydrogen) before it enters the fuel injection chamber. first H2 and O, then H4 and O2 then H8 and O4?? Who is the mathematician here? I'm not him. Peter can tell you.

There is para-hydrogen and ortho-hydrogen molecules. Ortho-hydrogen molecules will cluster and stick together, as they pass through 3 cells or more they cluster together more and more, their proton travels in the same direction, when finally sent to the combustion chamber they have 2-1/2 times the explosive power than gasoline!

Para-hydrogen are hydrogen molecules that will run together but have repelling protons to each other, therefore the clustering does not happen, they are less combustive than ortho-hydrogen. If you produce ortho hydrogen, then this also creates deuterium in which is what you want. deuterium build up on the cylinder walls, values helps oxidation from happening.

Now Stan used one tall wide cell with 3 tubes inside one large tube. 12" diva. and about 24" tall. Go look at his files.

To increase the power of the hydrogen, he irradiated it making deuterium. The extra proton was more than enough to allow the engine to achieve full power. It is good to get Deuterium built up in your piston walls, from the hydrogen so the water exhaust will not rust out the motor. They say AMSCO synthetic oil helps deal with the water in the oil better, helps it vaporize the water molecules.

Unfortunately, state officials decided the radioactive source under the hood would not be safe for widespread use. They did however allow Herman to continue driving the car and he put nearly 30, 000 miles on the car running on hydrogen. Realizing the technology could be improved, Herman went back to the drawing board.

It is kinda of ironic in that is exactly what a Ballard fuel cell is also doing, when in use in the new Hybrid Cars. The Ballard Fuel Cell is radioactively produce hydrogen to burn mixed with the air and the gasoline. The new hybrid cars are just as safe, except they use 1/2 gas and 1/2 electric. The Hybrids also contain radioactive batteries. The only difference was Herman's Wonderful car ran for FREE and with the new hybrid cars, you still have to PURCHASE the GASOLINE.

Yes the Mean Green Dancing Herman Machine was in the heart of every reader passing by with a BRAIN. Addicted to oil you drive to work, paying the largest corp. the largest profit in American history ever! Last quarter of 2004's profit from Exxon/Mobil exceeded the record for the largest quarter profit of 8 billion dollars. We are all guilty, unless you walk to work ride a bike, or enjoy an electric train.

The Green Machine also employed onboard electrolysis, meaning that to fill the gas tank, Herman would pour in distilled water.

and a little se cert Electrolyte KOH (1-5% solution to water, is all)

Yes there is a car that "runs on water." The car is now parked in the research facilities at MTSU.

Just like the TESLA statue at Niagara Falls, NY, it is way off to the side. And Edison's bust is real big in the middle with lights shinning on him. and he didn't even invent AC electricity, he was angry with Tesla's invention of AC, because it made his DC look non efficient. Today in all our households, we use AC electricity. It could have also been FREE wireless electricity. J.P. Morgan quit funding Tesla's FREE electricity Tower, because he could not find where to put the meter.

Next 10,000 people with water powered cars can join the STAN MEYERS 10.000 DUNE BUGGY PLANET MARATHON CLUB.

All truth passes through three stages: First, it is ridiculed; Second, it is violently opposed; and
Third, it is accepted as self-evident. -- Arthur Schopenhauer (1788-1860)

Fuel System for Internal Combustion System and Adapter for Use in Same

USP # 5,852,993

1998-12-29

Applicant: HERMAN P ANDERSON TECHNOLOGIES (US)
Classification: - international: F02B43/00; F02M21/02; F02B43/00; F02M21/02; (IPC1-7): F02M57/06; - European: F02B43/00; F02M21/02A
Also published as: US6119651 (A1)

Abstract -- The internal combustion engine fuel system described includes a structure for mixing the alternative fuel, preferably hydrogen, with oxygen in ambient air to stratify the fuel. The system includes an adapter, and the adapter includes a housing mounted between spark plug and cylinder of the internal combustion engine. A plug is placed within the housing. The plug has ridges or grooves on its outer surface that act as mixing structures. Thus, when hydrogen is introduced into the adapter housing it is mixed with ambient oxygen within the chamber as it flows over the plug. The mixing structures in the housing create a vortexing action as the hydrogen flows over the plug and towards the cylinder of the engine. An electrode protrudes from the plug towards the cylinder. The electrode is preferably platinum and generates the necessary spark to create combustion of the hydrogen/air mixture adjacent to the cylinder to thereby power the cylinder in the engine. A platinum electrode is preferably used because it enhances a catalytic conversion of combustion by-products to more environmentally compatible products.

Description

BACKGROUND OF THE INVENTION

The present invention relates generally to a fuel system for internal combustion engines that enables the invention to utilize alternative fuels; and, more particularly to an improved fuel system for an internal combustion engine and an adapter for use in same.

The problems of air pollution caused by automobiles, lawn mowers and other vehicles that have internal combustion engines powered by gasoline is well documented. This problem is particularly described in an article in the San Diego Union Tribune, Wednesday, Sep. 25, 1996 and in Popular Science, August, 1996. Indeed, under the Clean Air Act, in the next few years cars that do not run on standard fossil fuels like gasoline will be required in several states. Currently, there are no vehicles available to meet this need.

Thus, it will be appreciated by those skilled in the art that there has been a push to seek other fuels for use in internal combustion engines. These fuels include methane, propane and gasohol.

Hydrogen has also been characterized as a promising fuel source. See Department of Energy publication entitled "Hydrogen Fuel", printed in 1978, U.S. Government Printing Office, U.S. Department of Energy, Office of Public Affairs, Washington, D.C. 20585. Particularly, the graph presented in FIG. 6, which is copied from this publication, shows the potential for hydrogen in BTUs/Lb. However, the mass energy density for hydrogen is low; and thus, hydrogen needs to be compressed before its energy potential can be realized. No prior art fuel system has been able to capture the energy of hydrogen.

Several fuel systems for use with hydrogen have been proposed. Examples are described in U.S. Pat. Nos. 4,167,919; 4,253,428; 4,016,836; 4,178,882; 5,222,993; 5,085,176; and 5,085,176. The problem with these prior art fuel systems is they cannot can take advantage of the alternative fuels to generate sufficient power from the fuels to drive an internal combustion engine for use in a lawn mower, automobile or other vehicle. As noted above, this is a particular problem when hydrogen is used as a fuel. Additionally, the prior art systems do not address the problem of back fire, i.e. undesired explosion of the fuel in the cylinder during the exhaust stroke of the internal combustion engine.

What is needed, then, is a fuel system for an internal combustion engine that provides a way to generate sufficient power from the alternative fuels and that reduces backfire problems. Such a system is lacking in the prior art.

SUMMARY OF THE INVENTION

It is an object of this invention to provide an improved fuel system for use with alternative fuels.

It is a further object of this invention to provide an improved fuel system for use particularly with hydrogen, and particularly to enhance the mass energy density of hydrogen.

It is still a further object of this invention to provide an adapter for use in a fuel system for an internal combustion engine that enhances the power obtained from the alternative fuels.

It is still a further object of this invention to provide an improved fuel system for an internal combustion engine that does not present the environmental hazards of a standard gasoline engine by providing reduced or zero emission of environmentally harmful gases.

It is yet a further object of this invention to provide an improved fuel system for an internal combustion engine that can use an alternative fuel and can use gasoline to facilitate the transition from gasoline to alternative fuels.

It is yet a further object of this invention to provide an improved fuel system for an internal combustion engine that reduces backfire problems.

It is yet a further object of this invention to provide an improved fuel system for an internal combustion engine that reduces backfire problems by cooling the electrode in the spark plug with the hydrogen gas fuel.

It is still a further object of this invention to provide an adapter for use in a fuel system for an internal combustion engine that enhances the power obtained from the alternative fuels.

It is yet a further object of this invention to provide a direct injection fuel system wherein fuel is injected directly into the cylinder.

It is yet a further object of this invention to provide a way to convert the standard induction fuel system of a lawnmower to a direct injection fuel system wherein fuel is injected directly into the cylinder.

It is yet a further object of this invention to provide a way to convert the indirect injection fuel system of an automobile to a direct injection fuel system wherein fuel is injected directly into the cylinder.

The internal combustion engine fuel system of this invention includes a structure for mixing the alternative fuel, preferably hydrogen, with oxygen in ambient air to stratify the fuel. The term "alternative fuels" is known in the art and is meant to refer to fuels other than conventional gasoline.

The invention comprises an adapter, the adapter including a housing mounted between spark plug and cylinder of the internal combustion engine. A plug is placed within the housing. The plug has ridges or grooves on its outer surface that act as mixing structures. Thus, when hydrogen is introduced into the adapter housing it is mixed with ambient oxygen within the chamber as it flows over the plug. The mixing structures on the plug create a vortexing action as the hydrogen flows over the plug and towards the cylinder of the engine.

An electrode protrudes from the plug towards the cylinder. The electrode is preferably platinum and generates the necessary spark to create combustion of the hydrogen/air mixture adjacent to the cylinder to thereby power the cylinder in the engine. A platinum electrode is preferably used because it enhances a catalytic conversion of combustion by-products to more environmentally compatible products.

Thus, the combination of the compression action generated by the conventional piston and push rod within the cylinder of the engine in conjunction with the hydrogen/air mixing structure that vortexes the hydrogen/air create compressed hydrogen that is mixed with a combustion facilitator, i.e. oxygen in the ambient air to enable the system of this invention to capture the abundant energy found in hydrogen fuel.

The enhanced mixing capabilities of this invention is also adaptable for use with other alternative fuels such as natural gas, alcohol, propane and the like.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a plan view of the fuel system of this invention with a lawn mower shown in phantom.

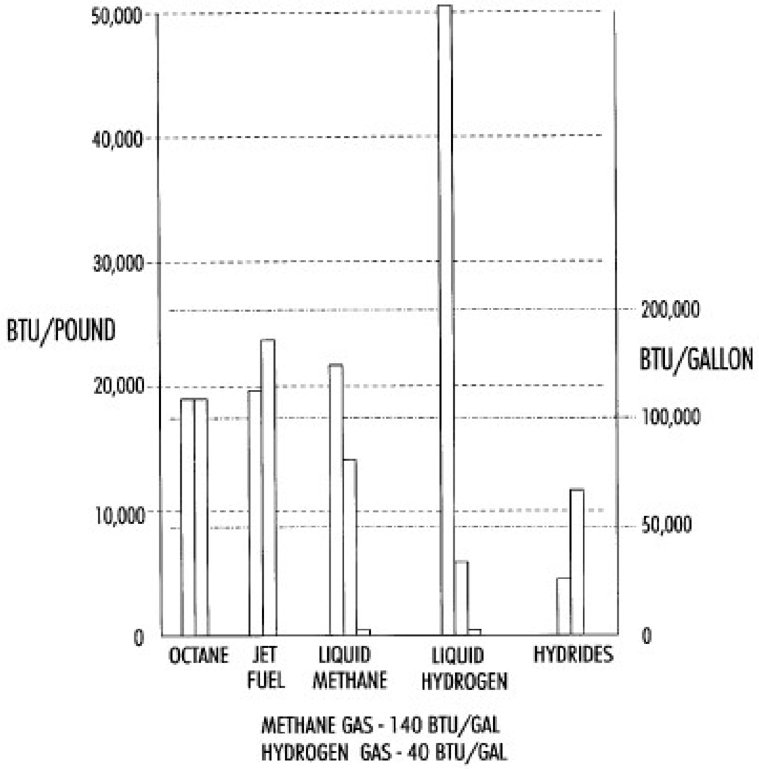

FIG. 6

DESCRIPTION OF THE PREFERRED EMBODIMENT

Referring now to the drawings, wherein like reference numerals refer to like parts throughout, the fuel system is referred to generally at 10. The fuel system of this invention is contemplated for use with an internal combustion power system, such as an internal combustion engine or such as a home heating system. Fuel system 10 is portrayed in this case as connected to a standard lawn mower. The lawn mower is shown in phantom at 12 in FIG. 1. The lawn mower is a conventional lawn mower as can be purchased from a company such as Murray of Ohio. The internal combustion engine in the lawn mower is a standard 4-cycle engine with two cylinders and develops 18 horsepower. A suitable example can be purchased from Briggs & Stratton, Milwaukee, Wis., 53201.

Referring particularly to FIG. 1, system 10 includes fuel tank 14 that is mounted to lawn mower 12 via mounting assembly 15. In the preferred embodiment, fuel tank 14 includes hydrogen gas. Accordingly, for the purposes of the foregoing detailed description, hydrogen gas will be described.

A line 22 begins at fuel tank 14 and proceeds to back-flow valve 16. Back-flow valve 16 is a standard valve and is available from AirCo Gases Company, 575 Mountain Avenue, Murray Hill, N.J. 07974, part no. WCS CV-4M. PSI tank gauge 19 is inserted in line 22 between back-flow valve 16 and flow pressure gauge 18. PSI tank gauge 19 is available from AirCo Gases Company also, part no. WCS CV-5M, and serves as an indicator of fuel remaining in the tank 14. Flow pressure gauge 18 is used to monitor the flow of the hydrogen in pressure units. The flow is started using valve 16. The optimal flow pressure is 25 pounds of flow pressure from the tank 14 to the cylinder of the engine.

The flow of hydrogen is regulated via valve 20 that is part of gauge 18. Thus, when valve 20 is opened, hydrogen proceeds through line section 22 to hydrogen flow solenoid 26A. The user can access the hydrogen fuel by flipping hydrogen flow switch 24A into the "on" mode so that hydrogen gas in line 22 can proceed through hydrogen flow solenoid 26A and into line section 28.

Throttle 30 regulates the flow of hydrogen from line section 28 into line section 29 and ultimately, to engine 13.

Throttle 30 is connected to throttle pedal 50 via includes throttle cable 48. Throttle pedal 50 also operates the butterfly valves in the carburetor in engine 13 in a conventional manner.

As an option, the throttle can be controlled electronically by a digital fuel controller product. Such a product is commercially available from Autotronic Controls Corp., 1490 Henry Brennan Drive, El Paso, Tex. 79936.

Line portion 29 proceeds through splitter 32 and is split into upper line 34 and lower line 36. Lines 34 and 36 proceed to adapters 38. Additional back-flow prevention valves 39 and 41 are mounted between lines 34 and 36 and adapters 38. Braided Teflon.RTM. is the preferred material for the fuel lines of the system.

Battery 42 is connected via battery cable 43 to magneto 44. Magneto 44 then controls the current through spark plug lines 46 to adapters 38 in a conventional manner. Thus, the regulation of the spark that ignites the fuel in the cylinder of engine 13 is conventional. Additionally, the intake of air into the engine 13 is accomplished through the standard carburetor system of engine 13. In a car, the sparking of the spark plugs can be controlled by the standard distributor/battery ignition system.

A second solenoid 26B controls the flow of gasoline from tank 23 through gasoline line 52. Solenoid 26B is controlled by switch 24B. Throttle 30 is connected to gasoline line 52 and can also be used to control the flow of gasoline to engine 13. Thus, this invention can be used with both an alternative fuel and gasoline.

Referring now to FIGS. 2, 3 and 4, the adapter 38 of this invention is shown in more detail. Adapter 38 includes housing 60. A threaded port 62 is formed into housing 60 through port block 64. Hydrogen lines are threadably connected to the adapter 38 via port 62. Port 62 is also referred to as an entrance port.

Adapter 38 also includes spark plug 66 which is effectively a standard spark plug except for the modification to the electrode as described below. Spark plug 66 includes a threaded end 68 which is threadably received in the threaded upper end 70 of housing 60. Spark plug wires 46 (as seen in FIG. 1) are connected to connector end 72 of spark plug base 66.

Electrode 76 protrudes from spark plug 66 and is of a length sufficient so that the threaded tip 77 (best seen in FIGS. 3 and 4) of the electrode 76 is proximate to the cylinder of the internal combustion engine when the adapter 38 is mounted. In one embodiment the electrode 76 is co-terminus with an exit port 88 of the adapter 38. This is most clearly shown in FIG. 4. Electrode 76 is preferably platinum to enhance catalysis of combustion by-products, as will be more fully discussed below.

Adapter 38 also includes plug 79. Plug 79 includes an axial internal void space 80. Thus, plug 79 fits over electrode 76 via internal void space 80. Plug 79 preferably comprises a ceramic material that acts as a good insulator. A suitable source for ceramic plug 79 is AM/PRO Machinery, Inc. 134 Church Street, Plain City, Ohio 43064-1321.

An important aspect of this invention is found on the external surface of plug 79. An annular groove 82 is formed on the surface of plug 79 near its distal end 81 so as to be proximal to the port 62 where hydrogen enters housing 60. Two stratifying grooves 84 proceed along the surface of plug 79 until they reach its distal end 83. It is these mixing structures, i.e. annual groove 82 and stratifying grooves 84, that facilitate the improved power generation from alternative fuels as provided by this invention. It will be apparent to those skilled in the analogous arts that the mixing structure may be formed on an inner surface 60i of the adapter housing 60. Alternatively, a combination of vortex producing structures may be attached to, and preferably integral with, both the plug 79 and the adapter housing inner surface 60i. Also, any conventional vortex producing means would be sufficient, i.e. grooves, per se, are not required. An entrance area 62a proximate the entrance port 62 is typically defined between the housing inner surface 60i and the external surface of plug 79. The external surface of plug 79 typically includes the grooves 84. So, the entrance area 62a is the volume of space within the housing, proximate the entrance port 62, which the gas will be able to occupy. This is most clearly shown in FIG. 4.

On threaded tip 77 of electrode 76, there are mounted a spacer nut 78 and a spark gap nut 85. As best seen in FIG. 2, the spark gap nut 85 includes a protrusion 85a that provides the spark gap between electrode 76 and periphery 89 of the exit port 88 of housing 60. The exit port 88 includes an exit area 88a. This is shown most clearly in FIGS. 2 and 4. The exit area 88a is no larger than the entrance area 62a. If the exit area 88a is smaller than the entrance area 62a, the pressure on the gas will increase. This increases the rate at which the gas is expelled from the plug 79, typically out through grooves 84. The electrode 76 is substantially co-terminus with the plug distal end 83 (seen most clearly in FIG. 2). Thus, the electrode 76 is substantially co-terminus with the exit port 88 or exit area 88a. Note that tip of the electrode 77 is preferably proximate with the exit area 88a because this is the location of greatest mixing. This is most clearly seen in FIG. 4. Preferably, the spark gap nut 85 is brass and the preferred spark gap distance is 25/1000 of an inch.

As best seen in FIG. 4, where arrows represent gas flow, hydrogen gas flows into chamber 60 via port 62. The hydrogen gas cools electrode 76, which facilitates combustion. Stratifying grooves 84, preferably there are two, act to mix the hydrogen that is flowing into housing 60 with ambient air therein. Though, more or less vortex creating grooves (a.k.a. stratifying grooves) may be desired. Typically, this will depend on the relative dimensions of the grooves and diameter of the plug as well as the pressure and velocity of the mixture in the housing. The mixing occurs within void space 86 of housing 60 and creates a vortexing or tornado action. Plug 79 tapers as it proceeds from its distal end 81 to its proximal end 83. Thus, proximal end 83 is smaller in diameter than distal end 81. This provides additional space within void space 86 for the mixing of the hydrogen and air. The stratified hydrogen/air are twisting in a vortex fashion when leaving housing 60 via exit port 88. The vortexing action produced by grooves 84 on the plug 79 creates a "tornado" 110 of hydrogen/air with a hollow center that generates a vacuum. Similar effect, or vortex flow path, would result were the grooves to be placed on the housing. The vacuum propels the hydrogen/air mixture into the cylinder of the engine for combustion. Such mixing cannot be accomplished in a conventional induction system.

Referring now to FIG. 5, a schematic of the system of this invention is portrayed, with arrows representing gas flow. Hydrogen flows in through port 62 through adapter 38 and into cylinder 92. Air enters cylinder 92 through air intake 90 and air intake valve 91. The stratified hydrogen/air mixture is compressed in the compression stroke of the engine via piston 94 and push rod 96, which are standard structures in an internal combustion engine. In the power stroke shown in FIG. 5-C, a spark is generated in the compressed stratified hydrogen/air mixture ignites and drives piston 94 and push rod 96 to power the engine.

The mass energy density of hydrogen is enhanced through the increased pressure on the hydrogen exerted by piston 94 on the hydrogen/air mixture within the cylinder 92 in the uptake stroke in an internal combustion engine. The pressurized and well-mixed hydrogen/air mixture is rapidly ignited through the spark because hydrogen has a fast flame front. This reduces problems with timing. Thus, the energy store found in hydrogen is captured through this system via the compression of the hydrogen gas within cylinder 92 and via the thorough mixing of hydrogen and air provided by adapter 38.

In addition, in the exhaust phase in a four cycle engine a second spark is generated from the plug to ensure complete combustion of by-products. This is enhanced by using an electrode made of platinum. Exhaust leaves cylinder 92 through exhaust port 98. Exhaust port 98 is closed during other phases by exhaust outlet valve 100.

In the exhaust stroke, because air valve 91 is closed, the substantial component of the gases in cylinder 92 is hydrogen. This is also accomplished due to the fact that in the system of this invention, the hydrogen is continuously flowing. When this spark interacts with what is predominately hydrogen, a plasma is formed. This plasma blocks back-flow of air from exhaust port 98. Prevention of back-flow of air prevents the hydrogen fuel system from backfiring, which is another common problem of hydrogen fuel systems. In effect, then, the plasma formed by the hydrogen acts as a virtual valve in that the plasma blocks the back-flow of air.

When the plasma of the hydrogen is generated as described above, UV radiation is generated which also facilitates consumption of combustion by-products. This increases the environmental friendliness of the system.

In addition to hydrogen the following fuels can be used in this system: natural gas; alcohol; gasohol; propane and buthane. A mixture of hydrogen and natural gas can also be used. As noted above, gasoline can be used in this system when solenoid 26 is used to stop the flow of hydrogen.

Further, it is contemplated that an adapter that is described herein for use with an internal combustion engine can also be used with a home heating system such as a home heating system that may currently use natural gas. The vortexing action created by the plug would enable appropriate power to be captured from the hydrogen fuel so as to effectively heat a home.

Thus, the apparatus and system of this invention provides an effective means to use alternative fuels. The use of alternative fuels can enhance the environment by reducing the use of conventional gasoline and the environmentally detrimental by-products caused by the consumption thereof.

Thus, although there have been described particular embodiments of the present invention of a new and useful "Fuel System For Internal Combustion System And Adapter For Use In Same", it is not intended that such references be construed as limitations upon the scope of this invention except as set forth in the following claims. Further, although there have been described certain dimensions used in the preferred embodiment, it is not intended that such dimensions be construed as limitations upon the scope of this invention except as set forth in the following claims.

United States Patent 6,119,651

September 19, 2000

Hydrogen Powered Vehicle, Internal Combustion Engine, and Spark Plug for use in same

Abstract --- The internal combustion engine fuel system described includes a structure for mixing the alternative fuel, preferably hydrogen, with oxygen in ambient air to stratify the fuel. The system includes an adapter, and the adapter includes a housing mounted between spark plug and cylinder of the internal combustion engine. A plug is placed within the housing. The plug has ridges or grooves on its outer surface that act as mixing structures. Thus, when hydrogen is introduced into the adapter housing it is mixed with ambient oxygen within the chamber as it flows over the plug. The mixing structures in the housing creates a vortexing action as the hydrogen flows over the plug and towards the cylinder of the engine. An electrode protrudes from the plug towards the cylinder. The electrode is preferably platinum and generates the necessary spark to create combustion of the hydrogen/air mixture adjacent to the cylinder to thereby power the cylinder in the engine. A platinum electrode is preferably used because it enhances a catalytic conversion of combustion by-products to more environmentally compatible products. The present invention also teaches a spark plug producing a hotter spark for a hydrogen fuel system. Also taught is a hydrogen powered vehicle with reduced emissions by producing a spark during the power stroke and the exhaust stroke. Methods for reducing exhaust pollution are also taught. Methods of reducing exhaust pollution by generating a plasma are taught as well.

Description

BACKGROUND OF THE INVENTION

The present invention relates generally to a fuel system for internal combustion engines that enables the invention to utilize alternative fuels; and, more particularly to an improved fuel system for an internal combustion engine and an adapter and spark plug for use in same.

The problems of air pollution caused by automobiles, lawn mowers and other vehicles that have internal combustion engines powered by gasoline is well documented. This problem is particularly described in an article in the San Diego Union Tribune, Wednesday, Sep. 25, 1996 and in Popular Science, August 1996. Indeed, under the Clean Air Act, in the next few years cars that do not run on standard fossil fuels like gasoline will be required in several states. Currently, there are no vehicles available to meet this need.

Thus, it will be appreciated by those skilled in the art that there has been a push to seek other fuels for use in internal combustion engines. These fuels include methane, propane and gasohol.

Hydrogen has also been characterized as a promising fuel source. See Department of Energy publication entitled "Hydrogen Fuel", printed in 1978, U.S. Government Printing Office, U.S. Department of Energy, Office of Public Affairs, Washington, DC 20585. Particularly, the graph presented in FIG. 6, which is copied from this publication, shows the potential for hydrogen in BTUs/Lb. However, the mass energy density for hydrogen is low; and thus, hydrogen needs to be compressed before its energy potential can be realized. Hydrogen is a "dry fuel" that is more difficult to ignite than "wet fuels." It becomes more difficult to ignite when it is cooled. However, cooling is preferred in most systems to avoid premature ignition of the fuel. Other systems deliver the hydrogen under pressure to prevent ignition in the supply line, which is a form of pre-ignition. No prior art fuel system has been able to capture the energy of hydrogen.

Several fuel systems for use with hydrogen have been proposed. Examples are described in U.S. Pat. Nos. 4,167,919; 4,253,428; 4,016,836; 4,178,882; 5,222,993; 5,085,176; and 5,085,176. The problem with these prior art fuel systems is they cannot take advantage of the alternative fuels to generate sufficient power from the fuels to drive an internal combustion engine for use in a lawn mower, automobile or other vehicle. As noted above, this is a particular problem when hydrogen is used as a fuel. Additionally, the prior art systems do not address the problem of back fire, i.e. undesired explosion of the fuel in the cylinder during the exhaust stroke of the internal combustion engine.

Premature ignition or backfire is often a problem with hydrogen fueled systems. U.S. Pat. No. 4,383,198

(Hosking) teaches a fuel injection spark plug with a pre-cooling chamber to avoid premature ignition indentination of a gaseous fuel supplied to the spark plug. U.S. Pat. No. 4,383,198, Hosking, entitled "Fuel Injection Spark Plug", issued May 10, 1983, is hereby incorporated herein by reference. However, cooling hydrogen makes it more difficult to ignite. This is because hydrogen is a dry fuel whereas gas is generally considered a wet fuel. Thus to reduce fuel pollution one prefers to utilize a fuel such as hydrogen and ignite it with a hotter spark.

One patent discussing very high energy (VHE) ignition systems is U.S. Pat. No. 5,207,208 issued to Ward, entitled "Integrated Convertor High Power CD Ignition", issued May 4, 1993. U.S. Pat. No. 5,207,208 is hereby incorporated herein by reference. Pat. '208 teaches very high energy ignition systems, for instance on the order of 36K volts. It teaches voltage doubling utilizing pulsating sparks of peak current on the order of two amps. While 36K volts may at times be adequate, it is preferable to achieve a higher voltage in the ignition chamber when using hydrogen.

It is known in the art to use a direct ignition system, also referred to as a distributorless ignition system, to increase the spark plug voltage. Such direct ignition systems use a "waste spark" method of spark distribution. Each cylinder is paired with its opposing cylinder in the firing order (1-4, 2-3, on a four cylinder, 1-4, 2-5, 3-6 on a V6) so that one cylinder on compression fires simultaneously with its opposing cylinder on exhaust stroke. Since the cylinder on exhaust stroke requires very little of the available voltage to fire its plug, most of the voltage is used to fire the cylinder on the compression stroke.

U.S. Pat. No. 4,462,380 discusses a distributorless ignition system. U.S. Pat. No. 4,462,380 entitled "Enhanced Spark Energy Distributorless Ignition System" issued Jul. 31, 1984 by Asik is hereby incorporated herein by reference. Pat. '380 teaches a distributorless ignition system of an internal combustion engine which has a supplementary spark energy module to increase spark energy. Each high voltage terminal is connected to a single spark plug and each ignition coil primary is alternately energized and quickly de-energized, producing opposite polarity ignition voltages at each coil terminal. As a result, pairs of spark plugs are alternately fired, with each firing pair occurring in a compression or exhaust stroke and thereby providing the proper ignition to the engine. Asik asserts that firing a spark plug does not affect engine performance or emissions. As taught by the instant invention this is incorrect for hydrogen fuels when the exhaust is sparked at a sufficient voltage.

U.S. Pat. No. 5,146,882 (Brinkman) teaches use of specific wet fuel mixtures in conjunction with direct ignition systems (D.I.S.). It teaches that technical breakdown voltages for typical spark plugs are on the order of 15-20 kV and DIS typically yield between 30 kV-40 kV. U.S. Pat. No. 5,146,882, entitled "Method And Apparatus For Cold Starting A Spark Ignited Internal Combustion Engine Fueled With An Alcohol-Based Fuel Mixture", by Brinkman, et al., issued Sep. 15, 1992, is hereby incorporated herein by reference. The previously referenced prior art discusses alternate fuels and fuel systems but does not teach a method of achieving a sufficient voltage with a hydrogen system.

What is needed, then, is a fuel system for an internal combustion engine that provides a way to generate sufficient power from the alternative fuels and that reduces backfire problems. Such a system is lacking in the prior art. Also lacking in prior art is a system utilizing alternate fuels with reduced pollution capabilities. Also lacking is a way of generating sufficient voltage spark to ignite the alternate fuel.

The following U.S. Patents discuss spark plugs designed for gas internal combustion engines to reduce radio frequency noise and interference. U.S. Pat. No. 4,224,554, entitled "Spark Plug Having A Low Noise Lever" issued to Nishio et al., Sep. 23, 1980 is hereby incorporated herein by reference. U.S. Pat. No. 4,029,990 entitled "Spark Plug Construction" issued to Nagy et al., Jun. 14, 1977 is hereby incorporated herein by reference.

SUMMARY OF THE INVENTION

It is an object of this invention to provide an improved fuel system for use with alternative fuels.

It is a further object of this invention to provide an improved fuel system for use particularly with hydrogen, and particularly to enhance the mass energy density of hydrogen.

It is an object to provide a hotter sparking plug to ignite the fuel.

It is still a further object of this invention to provide an adapter for use in a fuel system for an internal combustion engine that enhances the power obtained from the alternative fuels.

It is still a further object of this invention to provide an improved fuel system for an internal combustion engine that does not present the environmental hazards of a standard gasoline engine by providing reduced or zero emission of environmentally harmful gases.

It is yet a further object of this invention to provide an improved fuel system for an internal combustion engine that can use an alternative fuel and can use gasoline to facilitate the transition from gasoline to alternative fuels.

It is yet a further object of this invention to provide an improved fuel system for an internal combustion engine that reduces backfire problems.

It is yet a further object of this invention to provide an improved fuel system for an internal combustion engine that reduces backfire problems by cooling the electrode in the spark plug with the hydrogen gas fuel.

It is an object to reduce backfire by providing hydrogen at a sufficient pressure to reduce backfire and igniting it with a hotter spark (i.e. a higher voltage).

It is still a further object of this invention to provide an adapter for use in a fuel system for an internal combustion engine that enhances the power obtained from the alternative fuels.

It is a further object to generate a plasma field in a cylinder to burn residual exhaust and reduce emissions.

It is yet a further object of this invention to provide a direct injection fuel system wherein fuel is injected directly into the cylinder.

It is an object to provide a "2-fire" direct injection system, wherein the fuel is ignited during the power stroke and the exhaust stroke.

It is yet a further object of this invention to provide a way to convert the standard induction fuel system of a lawnmower to a direct injection fuel system wherein fuel is injected directly into the cylinder.

It is yet a further object of this invention to provide a way to convert the indirect injection fuel system of an automobile to a direct injection fuel system wherein fuel is injected directly into the cylinder.

The internal combustion engine fuel system of this invention includes a structure for mixing the alternative fuel, preferably hydrogen, with oxygen in ambient air to stratify the fuel. The term "alternative fuels" is known in the art and is meant to refer to fuels other than conventional gasoline.

The invention in one embodiment comprises an adapter, the adapter including a housing mounted between spark plug and cylinder of the internal combustion engine. A plug is placed within the housing. The plug has ridges or grooves on its outer surface that act as mixing structures. Thus, when hydrogen is introduced into the adapter housing it is mixed with ambient oxygen within the chamber as it flows over the plug. The mixing structures on the plug create a vortexing action as the hydrogen flows over the plug and towards the cylinder of the engine.

An electrode protrudes from the plug towards the cylinder. The electrode is preferably platinum and generates the necessary spark to create combustion of the hydrogen/air mixture adjacent to the cylinder to thereby power the cylinder in the engine. A platinum electrode is preferably used because it enhances a catalytic conversion of combustion by-products to more environmentally compatible products.

Thus, the combination of the compression action generated by the conventional piston and push rod within the cylinder of the engine in conjunction with the hydrogen/air mixing structure that vortexes the hydrogen/air create compressed hydrogen that is mixed with a combustion facilitator, i.e. oxygen in the ambient air to enable the system of this invention to capture the abundant energy found in hydrogen fuel.

The enhanced mixing capabilities of this invention is also adaptable for use with other alternative fuels such as natural gas, alcohol, propane and the like.

One embodiment of the present invention is for a hydrogen powered vehicle including an internal combustion engine operably connected to power the vehicle and adapted to connect to a hydrogen supply line. The internal combustion engine comprises a cylinder operably connected to the supply line; a piston operably disposed in the cylinder; and a spark plug having an electrode assembly in operable sparking communication with the cylinder, wherein the spark plug is capable of producing a spark of at least 45 kV.

Preferably the spark plug comprises a housing having a sparking end and a hollow chamber containing the electrode assembly. The electrode assembly comprises an electrode having a connector end and a sparking end, wherein the sparking end is positioned adjacent to the housing sparking end. The electrode assembly preferably comprises a coil electrically connected to the electrode connector.

Preferably the housing comprises a fuel inlet port in fluid communication with the supply line, and an insulator surrounding the electrode assembly, wherein the insulator is positioned in the hollow chamber. Preferably the insulator comprises an outer surface defining a first fuel channel having a first respective fuel exit port, wherein the first fuel channel is in fluid communication with the fuel inlet port and the fuel exit port exits into the cylinder.

The present invention also includes a method of operating an internal combustion engine comprising supplying hydrogen fuel to the engine and creating a spark in the cylinder during the power stroke and the exhaust stroke, wherein the spark created during the power stroke is at least 45 kV. In one embodiment the spark is at least 70 kV. In certain embodiments the method comprises generating plasma during the exhaust stroke. The exhaust fuel converts to an exhaust emission and coalesces with the plasma, thereby reducing fuel pollution.

Accordingly, it is an object in the invention to provide a spark plug producing a sufficiently hot spark to ignite hydrogen fuel, including cooled hydrogen fuel.

Another object of the present invention is to provide a device for reducing fuel exhaust emissions.

Another object of the present invention is to provide a cleaner burning engine.

Another object is to provide a spark plug for reducing emissions.

Another object of the present invention is to provide a device functional with dry fuels. Use of the term hydrogen, as discussed herein, is intended to encompass such dry fuels. However the term as used excludes such wet fuels as gas and alcohol.

Another object of the present invention is to provide an integrated fuel system adapted to provide these and objectives.

Other objects and advantages of the present invention will be apparent to those of skill in the art by reference to the teachings disclosed herein, including the attached drawings, detailed description of exemplary embodiments, and claims.

DESCRIPTION OF THE PREFERRED EMBODIMENT

Referring now to the drawings, wherein like reference numerals refer to like parts throughout, the fuel system is referred to generally at 10. The fuel system of this invention is contemplated for use with an internal combustion power system, such as an internal combustion engine or such as a home heating system. Fuel system 10 is portrayed in this case as connected to a standard lawn mower. The lawn mower is shown in phantom at 12 in FIG. 1. The lawn mower is a conventional lawn mower as can be purchased from a company such as Murray of Ohio. The internal combustion engine in the lawn mower is a standard 4-cycle engine with two cylinders and develops 18 horsepower. A suitable example can be purchased from Briggs & Stratton, Milwaukee, Wis. 53201.

Referring particularly to FIG. 1, system 10 includes fuel tank 14 that is mounted to lawn mower 12 via mounting assembly 15. In the preferred embodiment, fuel tank 14 includes hydrogen gas. Accordingly, for the purposes of the foregoing detailed description, hydrogen gas will be described.

A line 22 begins at fuel tank 14 and proceeds to back-flow valve 16. Back-flow valve 16 is a standard valve and is available from AirCo Gases Company, 575 Mountain Avenue, Murray Hill, N.J. 07974, part no. WCS CV-4M. PSI tank gauge 19 is inserted in line 22 between back-flow valve 16 and flow pressure gauge 18. PSI tank gauge 19 is available from AirCo Gases Company also, part no. WCS CV5M, and serves as an indicator of fuel remaining in the tank 14. Flow pressure gauge 18 is used to monitor the flow of the hydrogen in pressure units. The flow is started using valve 16. The optimal flow pressure is 25 pounds of flow pressure from the tank 14 to the cylinder of the engine.

The flow of hydrogen is regulated via valve 20 that is part of gauge 18. Thus, when valve 20 is opened, hydrogen proceeds through line section 22 to hydrogen flow solenoid 26A. The user can access the hydrogen fuel by flipping hydrogen flow switch 24A into the "on" mode so that hydrogen gas in line 22 can proceed through hydrogen flow solenoid 26A and into line section 28.

Throttle 30 regulates the flow of hydrogen from line section 28 into line section 29 and ultimately, to engine 13. Throttle 30 is connected to throttle pedal 50 via includes throttle cable 48. Throttle pedal 50 also operates the butterfly valves in the carburetor in engine 13 in a conventional manner.

As an option, the throttle can be controlled electronically by a digital

fuel controller product. Such a product is commercially available from Autotronic Controls Corp., 1490 Henry Brennan Drive, El Paso, Tex. 79936.

Line portion 29 proceeds through splitter 32 and is split into upper line 34 and lower line 36. Lines 34 and 36 proceed to adapters 38. Additional back-flow prevention valves 39 and 41 are mounted between lines 34 and 36 and adapters 38. Braided Teflon.RTM. is the preferred material for the fuel lines of the system.

Battery 42 is connected via battery cable 43 to magneto 44. Magneto 44 then controls the current through spark plug lines 46 to adapters 38 in a conventional manner. Thus, the regulation of the spark that ignites the fuel in the cylinder of engine 13 is conventional. Additionally, the intake of air into the engine 13 is accomplished through the standard carburetor system of engine 13. In a car, the sparking of the spark plugs can be controlled by the standard distributor/battery ignition system.

A second solenoid 26B controls the flow of gasoline from tank 23 through gasoline line 52. Solenoid 26B is controlled by switch 24B. Throttle 30 is connected to gasoline line 52 and can also be used to control the flow of gasoline to engine 13. Thus, this invention can be used with both an alternative fuel and gasoline.

Referring now to FIGS. 2, 3 and 4, the adapter 38 of this invention is shown in more detail. Adapter 38 includes housing 60. A threaded port 62 is formed into housing 60 through port block 64. Hydrogen lines are threadably connected to the adapter 38 via port 62. Port 62 is also referred to as an entrance port. The entrance port has an entrance area 62a.

Adapter 38 also includes spark plug 66 which is effectively a standard spark plug except for the modification to the electrode as described below. Spark plug 66 includes a threaded end 68 which is threadably received in the threaded upper end 70 of housing 60. Spark plug wires 46 (as seen in FIG. 1) are connected to connector end 72 of spark plug base 66.

Electrode 76 protrudes from spark plug 66 and is of a length sufficient so that the threaded tip 77 (best seen in FIGS. 3 and 4) of the electrode 76 is proximate to the cylinder of the internal combustion engine when the adapter 38 is mounted. In one embodiment the electrode 76 is coterminus with an exit port 88 of the adapter 38. This most clearly is shown in FIG. 4. Electrode 76 is preferably platinum to enhance catalysis of combustion by-products, as will be more fully discussed below.

Adapter 38 also includes plug 79. Plug 79 includes an axial internal void space 80. Thus, plug 79 fits over electrode 76 via internal void space 80. Plug 79 preferably comprises a ceramic material that acts as a good insulator. A suitable source for ceramic plug 79 is AM/PRO Machinery, Inc. 134 Church Street, Plain City, Ohio 43064-1321.

An important aspect of this invention is found on the external surface of plug 79. An annular groove 82 is formed on the surface of plug 79 near its distal end 81 so as to be proximal to the port 62 where hydrogen enters housing 60. Two stratifying grooves 84 proceed along the surface of plug 79 until they reach its distal end 83. It is these mixing structures, i.e. annual groove 82 and stratifying grooves 84, that facilitate the improved power generation from alternative fuels as provided by this invention. It will be apparent to those skilled in the analogous arts that mixing structure may be formed in the inner surface of the adapter housing 60.

Alternatively a combination of vortex producing structures is integral with both the plug 79 and adapter housing 60. Also any conventional vortex producing means should be sufficient groves, per se, are not required.

On threaded tip 77 of electrode 76, there are mounted a spacer nut 78 and a spark gap nut 85. As best seen in FIG. 2, the spark gap nut 85 includes a protrusion 85a that provides the spark gap between electrode 76 and periphery 89 of the exit port 88 of housing 60. The exit port 88 includes an exit area 88a. Preferably, the exit area 88a is no larger than the entrance area 62a, though this is not critical. Preferably, the spark gap nut 85 is brass and the preferred spark gap distance is 25/1000 of an inch. Of course, the electrode may be coterminus with the plug distal end 83.

As best seen in FIG. 4, where arrows represent gas flow, hydrogen gas flows into chamber 60 via port 62. The hydrogen gas cools electrode 76, which facilitates combustion. Stratifying grooves 84, preferably there are two, act to mix the hydrogen that is flowing into housing 60 with ambient air therein. Though more or less vortex creating grooves (stratifying grooves) may be desired. Typically this will depend on the relative dimensions of the grooves and diameter of the plug as well as the pressure or velocity of the mixture in the housing. The mixing occurs within void space 86 of housing 60 and creates a vortexing or tornado action. Plug 79 tapers as it proceeds from its distal end 81 to its proximal end 83. Thus, proximal end 83 is smaller in diameter than distal end 81. This provides additional space within void space 86 for the mixing of the hydrogen and air. The stratified hydrogen/air are twisting in a vortex fashion when leaving housing 60 via exit port 88. The vortexing action produced by grooves 84 on the plug 79 creates a "tornado" 110 of hydrogen/air with a hollow center that generates a vacuum. Similar effect would result were t he grooves to be placed on the housing. The vacuum propels the hydrogen/air mixture into the cylinder of the engine for combustion. Such mixing cannot be accomplished in a conventional induction system.

Referring now to FIG. 5, a schematic of the system of this invention is portrayed, with arrows representing gas flow. Hydrogen flows in through port 62 through adapter 38 and into cylinder 92. Air enters cylinder 92 through air intake 90 and air intake valve 91. The stratified hydrogen/air mixture is compressed in the compression stroke of the engine via piston 94 and push rod 96, which are standard structures in an internal combustion engine. In the power stroke shown in FIG. 5-C, a spark is generated in the compressed stratified hydrogen/air mixture ignites and drives piston 94 and push rod 96 to power the engine.

The mass energy density of hydrogen is enhanced through the increased pressure on the hydrogen exerted by piston 94 on the hydrogen/air mixture within the cylinder 92 in the uptake stroke in an internal combustion engine. The pressurized and well-mixed hydrogen/air mixture is rapidly ignited through the spark because hydrogen has a fast flame front. This reduces problems with timing. Thus, the energy store found in hydrogen is captured through this system via the compression of the hydrogen gas within cylinder 92 and via the thorough mixing of hydrogen and air provided by adapter 38.

In addition, in the exhaust phase in a four cycle engine a second spark is generated from the plug to ensure complete combustion of by-products. This is enhanced by using an electrode made of platinum. Exhaust leaves cylinder 92 through exhaust port 98. Exhaust port 98 is closed during other phases by exhaust outlet valve 100.

In the exhaust stroke, because air valve 91 is closed, the substantial component of the gases in cylinder 92 is hydrogen. This is also accomplished due to the fact that in the system of this invention, the hydrogen is continuously flowing. When this spark interacts with what is predominately hydrogen, a plasma is formed. This plasma blocks back-flow of air from exhaust port 98. Prevention of back-flow of air prevents the hydrogen fuel system from backfiring, which is another common problem of hydrogen fuel systems. In effect, then, the plasma formed by the hydrogen acts as a virtual valve in that the plasma blocks the back-flow of air.

When the plasma of the hydrogen is generated as described above, UV radiation is generated which also facilitates consumption of combustion by-products. This increases the environmental friendliness of the system.

In addition to hydrogen the following fuels can be used in this system: natural gas; alcohol; gasohol; propane and buthane. A mixture of hydrogen and natural gas can also be used. As noted above, gasoline can be used in this system when solenoid 26 is used to stop the flow of hydrogen.

Further, it is contemplated that an adapter that is described herein for use with an internal combustion engine can also be used with a home heating system such as a home heating system that may currently use natural gas. The vortexing action created by the plug would enable appropriate power to be captured from the hydrogen fuel so as to effectively heat a home.

Another embodiment of the invention is a hydrogen powered vehicle 200 shown in FIG. 7. The hydrogen powered vehicle 200 includes an internal combustion engine 210 operably connected to power the vehicle 200 and adapted to connect to a hydrogen supply 212 through a supply line 214.

Referring to FIG. 8, the internal combustion engine 210 comprises a cylinder 92 operably connected to the supply line 214. A piston 94 is operably disposed in the cylinder 92. A spark plug 216 having an electrode assembly 218 (not shown in FIG. 8) is in operable sparking communication with the cylinder 92, wherein the spark plug 216 is capable of producing a spark 220 (shown in FIG. 10) of at least 45 kilovolts. FIGS. 8-11 are substantially similar to FIGS. 5A-5D depicting schematic representations of a 4-cycle piston-cylinder engine. Other piston and cylinder embodiments will be apparent to those with skill in the art. FIG. 8 represents an intake stroke. FIG. 9 depicts a compression stroke. FIG. 10 depicts a power stroke, in which the spark plug 216 sparks. FIG. 11 depicts an exhaust stroke, where the spark plug 216 is sparking. Refer to FIGS. 5A-5D discussed earlier for further description of similar components of FIGS. 8-11.

FIG. 12 shows one embodiment of the spark plug 216 in an elevated side view. FIG. 13 shows a plan view of the spark plug 216 along line 13--13 shown in FIG. 12. FIG. 14 shows a plan view of the spark plug 216 in the direction of line 14--14 shown in FIG. 12.

FIG. 15 depicts a section view of the spark plug 216. FIG. 15, section view, depicts a representative spark plug 216. The spark plug shown in FIG. 15 comprises a housing 222 having a sparking end 224 and a hollow chamber 226 containing the electrode assembly 218.

FIG. 16 depicts the electrode assembly 218 removed from the hollow chamber 226. The electrode assembly 218 depicted in FIG. 16 comprises an electrode 228. The electrode 228 has a connector end 230 and a sparking end 232. As shown in FIG. 15 the sparking end 232 of the electrode 228 is positioned adjacent to the housing sparking end 224. The electrode assembly further comprises a coil 234 electrically connected to the electrode connector end 230.

Referring to FIGS. 10 and 11, wherein the piston 94 moves through a power stroke in FIG. 10 and an exhaust stroke in FIG. 11, the spark plug 216 is shown to fire during the power stroke and the exhaust stroke.

The electrode assembly 218 shown in FIG. 16 comprises a steel ball 236 positioned between the coil 234 and the electrode connector end 230. Other operable ball-coil-electrode arrangements will be apparent to those of skill in the art.

The spark plug 216 shown in FIG. 15 also comprises an insulator 238 surrounding the electrode assembly 218 and positioned in the hollow chamber 226. A ceramic pore 240 is shown stabilizing the insulator 238 in the hollow chamber 226. Other methods of locating the insulator in the hollow chamber will be apparent to those of skill in the art.

An elevated section view of the housing 222 is shown in FIG. 17. An elevated side view of the housing 222 is shown in FIG. 18. In the exemplary embodiment of the housing 222 shown in FIG. 18, the housing 222 comprises a fuel inlet port 242 in fluid communication with the supply line 214 (not shown). FIG. 19 depicts an exemplary embodiment of the insulator 238. The insulator 238, shown in FIG. 19, comprises an outer surface 244 defining a first fuel channel 246 having a first respective fuel exit port 248. The first fuel channel 246 is in fluid communication with the fuel inlet port 242. The fuel exit port 248 exits into the cylinder 292.

FIG. 20 shows a plan view of the insulator 228 shown in FIG. 19 along line 20--20. FIG. 21 shows a section view of the insulator 228 shown in FIG. 19 viewed along section line 21--21. FIG. 22 depicts a bottom plan view of the insulator 228 shown in FIG. 19 along line 22--22. FIG. 23 shows a section view of the insulator 228 cut through section line 23--23 shown in FIG. 19.

In the embodiment of the insulator 228 shown in FIGS. 19-22, the insulator outer surface 244 defines a plurality of fuel channels 250, including the first fuel channel 246. The fuel channels 250 include a plurality of respective fuel exit ports 252, including the first fuel exit port 248. This is shown clearly in FIG. 22. Preferably, the plurality of fuel channel exit ports 252 are spaced equally, or equi-distant, about the electrode 228. This is shown well in FIGS. 21 and 22.

Referring to FIGS. 15 and 17, one embodiment of the housing 222 sparking and 224 comprises a torridal ground electrode 254 positioned about the electrode sparking end 232 (shown in FIG. 15). Preferably the housing sparking end 224 and the electrode sparking end 232 are co-terminous. In one embodiment the first respective fuel exit port 248 is co-terminous with the housing sparking end 224 and the electrode sparking end 232.

More generally the present invention includes an internal combustion engine 210 adapted to operate on hydrogen fuel supplied through a supply line 214. Typically the engine comprises a first cylinder 92 in fluid communication with the supply line 214; a first piston 94 disposed in the first cylinder 92 to move through a power stroke and an exhaust stroke (See FIGS. 10 and 11) in the first cylinder 92. The engine 210 also comprises a spark plug 216 having a housing 222 including a sparking end 224 and an electrode assembly 218 located in the housing 222, wherein the sparking end 224 is in operable communication with the cylinder 92 and capable of producing a spark 220 of at least 45 kV. Preferably, the spark plug 216 fires during the power stroke and the exhaust stroke. In one embodiment the housing sparking end 224 comprises a torridal ground electrode 254. The electrode assembly 218 comprises an electrode 228 having a sparking end 230 capable of sparking toward the torridal ground electrode 254. Preferably the electrode assembly 218 comprises a coil 234 in electrical communication with the electrode 228.

In one embodiment the electrode assembly 218 comprises an electrode 228 having a sparking end 230 and a coil 234 electrically connected to the electrode 228 opposite the electrode sparking end 230. This is the embodiment shown in FIG. 15. Typically the spark plug 216 comprises an insulator 228 surrounding the electrode assembly 218. Preferably the insulator 228 includes a fuel channel 246 having a fuel exit port 248 near the electrode sparking end 232.

It will be apparent to those with skill in the art that the present invention also comprises a method of operating an internal combustion engine 210 comprising the steps of supplying hydrogen fuel to the engine 210; moving a piston 94 in a cylinder 92 through a power stroke and an exhaust stroke; creating a spark 220 in the cylinder 92 during the power stroke and the exhaust stroke, wherein the spark created during the power stroke is at least 45 kV; and supplying the fuel to a location sufficiently near the spark to ignite the fuel. This is shown well in FIGS. 10, 15 and 19.

The present invention also includes a method wherein the step of creating a spark 220 comprises passing an electric current (not shown) through an electrode assembly 218 including a coil 234 electrically connected to an electrode 218 having a sparking end 232; insulating the electrode assembly 218; and arcing the electric current from the electrode sparking end 232 to a ground electrode 254. The ground electrode 254 as shown in FIGS. 15 and 17 a toroidal ground electrode 254.

In certain embodiments the step of creating a spark 220 includes creating a spark 220 having at least 70 kV. Creating a spark of sufficient voltage will generally reduce the exhaust pollution. Typically this happens by generating a plasma or plasma field during the exhaust stroke. Thus, one method of the present invention further comprises the steps of generating plasma during the exhaust stroke; and allowing exhaust fuel converted to an exhaust state to coalesce with the plasma. This reduces exhaust pollution.

Thus, the apparatus and system of this invention provides an effective means to use alternative fuels. The use of alternative fuels can enhance

the environment by reducing the use of conventional gasoline and the environmentally detrimental by-products caused by the consumption thereof.

Thus, although there have been described particular embodiments of the present invention of a new and useful "Hydrogen Powered Vehicle, Internal Combustion Engine, And Spark Plug For Use In Same", it is not intended that such references be construed as limitations upon the scope of this invention except as set forth in the following claims. Further, although there have been described certain dimensions used in the preferred embodiment, it is not intended that such dimensions be construed as limitations upon the scope of this invention except as set forth in the following claims.

THE NORRIS PETERS CO., PHOTO-LITHO., WASHINGTON, D. C.

UNITED STATES PATENT OFFICE.

ROBERT J. WALLACE, OF DENVER, COLORADO.

BUSINESS-COLLEGE CABINET.

SPECIFICATION forming part of Letters Patent No. 585,299, dated June 29, 1897.

Application filed April 7, 1897. Serial No. 631,189. (No model.)

To all whom it may concern:

Be it known that I, ROBERT J. WALLACE, a citizen of the United States of America, residing at Denver, in the county of Arapahoe and State of Colorado, have invented certain new and useful Improvements in Business-College Cabinets; and I do declare the following to be a full, clear, and exact description of the invention, such as will enable others skilled in the art to which it appertains to make and use the same, reference being had to the accompanying drawings, and to the figures of reference marked thereon, which form a part of this specification.

My invention relates to improvements in cabinets for use in colleges and other institutions where bookkeeping and business methods are taught; and it consists of the features hereinafter described and claimed, all of which will be fully understood by reference to the accompanying drawings, in which is illustrated an embodiment thereof.

In the drawings, Figure 1 is a vertical longitudinal section taken through my improved cabinet. Fig. 2 is a front view of a cabinet, partly in section, taken on the line *y y*, Fig. 3. Fig. 3 is a fragmentary section illustrating the locking mechanism. This view is taken on the line *x x*, Fig. 2. Fig. 4 illustrates a detail of construction.

Similar reference-characters indicating corresponding parts in the views, let the numeral 5 designate the sides, 6 the bottom, and 7 the top, of the cabinet. These walls are preferably composed of wood, the top and bottom being interiorly grooved to receive the partitions 8, composed of cardboard or other suitable material. These partitions occupy positions parallel with the side walls 5, and they separate the inclosed space into a series of compartments for the reception of envelops containing instructions in business transactions, the method of entering them in books, the manner of preparing these papers, together with samples and forms. These envelops may also contain money, blank forms of business-papers for the student to fill out, business-papers already prepared in the business the student is doing or which is being done by the person for whom the student is keeping books. The envelops also contain model papers and books to aid the student in his work.

In the front end of the cabinet and located on opposite sides of the partitions 8 are two vertical rollers 9, whose extremities are respectively journaled or pivoted in the top and bottom of the cabinet. As shown in the drawings, the rollers consist of hollow cylinders, preferably composed of tin, having closed ends which are apertured to receive loose spindles 10, which are passed therethrough and protrude sufficiently to form journals which engage sockets in the top and bottom walls of the case or cabinet. The lower sockets do not extend entirely through the bottom 6. Hence the spindles cannot drop through or escape from the cabinet, case, or box. The upper sockets pass entirely through the top of the box, which is recessed or slotted to receive a thin strip 25 of metal or other material which intersects the sockets and passes just above the spindle extremities. This strip prevents the spindles from dropping out when the cabinet is turned over. It is, however, removable, and when taken out the spindles may be removed and inserted at will. When the axles or spindles are taken out, the rollers are released, allowing any adjustment or regulation of the parts which may be necessary or desirable.

The two rollers are connected by two tapes 12 and 13, composed of metal or any other suitable material. The extremities of each tape are made fast to the rollers. The tape 13 is attached to the roller extremities below the partitions 8. The tape 12 is passed under and the tape 13 over each roller, so that as the rollers are turned one tape is winding upon while the other is unwinding from each roller. The tape 12 is located about midway between the top and bottom of the cabinet and is connected with a vertical slotted slide 14, whose extremities are T-shaped and engage suitable guide-grooves formed in the top and bottom of the case. It is divided where it is attached to the slide, since it must not cross the slot therein. This slot is narrow and adapted to register successively with the compartments formed by the partitions 8 as the slide is adjusted or moved. Hence as the slide is moved from the left toward the right (referring to Fig. 2) each envelop may be removed in succession from its compartment by drawing it therefrom through the slot in the slide. The width of the slot, however, will only permit the removal of one envelop at a time. Hence when any envelop has been returned to its compartment and the slide moved to the next compartment the previously-used envelop cannot be again taken from its compartment until the slide is moved backward or in the opposite direction. The cabinet is provided with locking mechanism to prevent this return movement, as hereinafter described.

The slide 14 is provided intermediate its extremities with an enlargement 14^a, to permit the insertion of the thumb and finger for the purpose of removing the envelops as the slide is adjusted. The partitions are provided with recesses 8^c to enable the student to easily grasp the envelops whose forward extremities project into the said recesses. The tape 12 prevents the removal of any envelop until the slide is so adjusted that its slot registers with the compartment containing the envelop.

One of the rollers is provided with a series of short vertical slots 10^a, adapted to be engaged by a spring dog or pawl 15, mounted on a suitable support. The dog normally engages the slots 10^a of the roller and is so constructed that it will permit the roller to turn freely in one direction, but lock it against movement in the opposite direction. Provision is made, however, for disengaging this dog from the roller and holding it in the disengaged position when it is desired to reverse the movement of the rollers. This may be accomplished in any suitable manner. As shown in the drawings, a lever 16 is fulcrumed on the casing at 17. The lower extremity of this lever is connected with the spring-dog 15 by means of a link 18, while the upper extremity of the lever lies in the path of a bolt projecting from the casing 19 of any suitable locking mechanism. This bolt is controlled by a suitable key 20 in the ordinary manner. The key is carried by the teacher or instructor. When the student is at work, the parts are in the position shown in full lines in Fig. 3. Hence the slide can be moved only in one direction.

The dotted lines in Fig. 3 show the position of the parts when the roller is unlocked. This is accomplished by turning the key 20 in the casing 19 and throwing the bolt outward to engagement with the upper extremity of the lever 16. This engagement of the bolt actuates the lever sufficiently to disengage the dog 15 from the roller.

The slide 14 may be formed of a single piece of wire bent into the desired shape, or it may be of any other desired construction. The slots 10^a engaged by the locking-pawl 15 should all be of the same width and the same distance apart. The arrangement is preferably such that every time the dog or pawl 15 passes from one notch to another the slide moves from one compartment to another of the case or cabinet. If desired, the partitions 8 may be omitted and the envelops may be of sufficient width to engage the grooves in the top and bottom of the case.

In describing the use of the device I will assume that it is locked—that is to say, that the spring dog or pawl 15 and its controlling-lever are in the position shown in full lines in Fig. 3, or so that the slide 14 may be moved in one direction only. I will further assume that the student is using the cabinet and that the direction of movement is from the left toward the right, referring to Fig. 2. As the slide is moved so that its slot registers with any compartment of the case he removes the envelop in that compartment, uses its contents, makes the necessary entries in his book, replaces the envelop and contents in its compartment, and moves the slide to the next compartment toward the right, and so on until every envelop has been removed and its contents used. It will be observed that by virtue of the engagement of the pawl 15 with the slots 10^a of the roller (see Fig. 4) the slide cannot be moved toward the left until the roller is released from engagement with the dog. This is done by the teacher or instructor at the proper time by inserting and turning the key 20 in the lock-casing 19 and projecting the bolt, thus throwing the parts to the position shown by dotted lines in Fig. 3. The slide may then be moved backward toward the left at will.

Some of the advantages of my improved cabinet will now be described. The matter contained in the envelops can be reached, used, and replaced by the student, but he cannot anticipate what he has before him, neither can he turn to instructions he has passed over to make up neglected work, thus making the process of his work very similar to that practiced in an office and yet permitting full instructions for each transaction with model entries, books, and business papers for similar but not like transactions. It makes it convenient to have matter of different kinds for each student who is working in any part of his course of study, so that there cannot be any copying in the schoolroom; it permits any desired variation in the work by changing the instructions and matter of one or more envelops in a cabinet; it permits (by having several cabinets) of having only a small portion of the student's work before him at any one time, so that he is not discouraged by seeing what is ahead of him; it allows the student to start his business course as bookkeeper for a business man who transacts the business and instructs the student how to make the proper entries and business papers; it makes it practicable to have business papers and cash pass through the student's hands the same as in a first-class business house; it permits the directing of the student in his actual business practice without his being able to anticipate or to gather up neglected work gone over; it permits the using of the same instructions many times over, thus lessening expenses; it allows the student to keep his papers in compact form and free from dust; it permits complete and full instructions with reference to each step of the work, thus relieving the teacher to a certain extent and making the student more self-reliant, and, finally, it permits each school using the cabinet to adopt such a system of instructions in bookkeeping and of business forms as it thinks best.

Between the sides 5 of the case and the outermost partition 8 are two compartments 22 not controlled by the tape 12. These are for the student's private use. In the top and bottom of the case are formed two grooves 23 in front of the slotted slide. They are for the insertion of a sliding front end piece, (not shown,) which may be employed when the cabinet is not in use. This feature permits the closing of the cabinet perfectly tight, whereby all dust is excluded. The opposite end of the cabinet is tightly closed by a suitable wall 4.

Having thus described my invention, what I claim is—

1. A cabinet of the class described adapted to hold envelops or documents, a slotted device movably connected with the open end of the cabinet, and means connected with the slotted device for preventing the removal or insertion of papers except by way of the slot in said movable slide.

2. A case or cabinet of the class described adapted to contain business papers and being open at one end or side, a slotted device attached to the open end of the case and having an enlargement intermediate its extremities to permit the insertion of the thumb and finger in removing papers, and means connected with the slide for preventing the insertion or removal of papers except by way of the slot in the slide.

3. A cabinet of the class described adapted to hold envelops or other papers or documents, a slotted device movably connected with the open end of the cabinet, and means connected with the slotted device for preventing the removal or insertion of papers, except by way of the slot in the slide, and suitable means for locking the slotted slide against movement in one direction.

4. A cabinet or case adapted to contain business papers and open at one end or side, a slotted slide connected with the open end of the case, rollers pivoted in the case, and a ribbon, tape, or flexible band 12 connected with the slide and having its extremities attached to the rollers, said tape being adapted to prevent the insertion or removal of papers except by way of the slot in the slide.

5. A cabinet or case adapted to contain business papers and open at one side or end, a slotted slide connected with the open end of the case, rollers pivoted in the case, and a ribbon, tape, or flexible band 12 connected with the slide and having its extremities attached to the rollers, said tape being adapted to prevent the insertion or removal of papers except by way of the slot in the slide, and suitable means engaging one of the rollers for locking the slide against movement in one direction, and another tape connected with the rollers, but adapted to wind in a direction opposite from the tape 12, whereby as one tape is winding up on each roller, the other tape is unwinding from the same roller.

6. A cabinet or case adapted to contain business papers and open at one end or side, a slotted slide connected with the open end of the case, rollers pivoted in the case, and a ribbon, tape, or flexible band 12 connected with the slide and having its extremities attached to the rollers, said tape being adapted to prevent the insertion or removal of papers, except by way of the slot in the slide, suitable means engaging one of the rollers for locking the slide against movement in one direction, said means comprising a spring-pawl normally engaging a ratchet of the roller.

7. A cabinet or case adapted to contain business papers and open at one end or side, a slotted device connected with the open end of the case, rollers pivoted in the case, and a tape having its extremities attached to the rollers, said tape being adapted to prevent the insertion or removal of papers except by way of the slot in the slide, suitable means engaging one of the rollers for locking the slide against movement in one direction, said means comprising a spring-pawl normally engaging a ratchet in the roller, and suitable means for disengaging the pawl from the roller, comprising a lever connected with the pawl, and a key-operated bolt for actuating the lever.

8. A cabinet or case divided by suitable partitions into a series of compartments, said cabinet being open at one end, a slotted slide connected with the open end of the case, and means connected with the slide for preventing access to the compartments of the case except by way of the slot in the slide.

In testimony whereof I affix my signature in presence of two witnesses.

ROBERT J. WALLACE.

[57] **ABSTRACT**

The internal combustion engine fuel system described includes a structure for mixing the alternative fuel, preferably hydrogen, with oxygen in ambient air to stratify the fuel. The system includes an adapter, and the adapter includes a housing mounted between spark plug and cylinder of the internal combustion engine. A plug is placed within the housing. The plug has ridges or grooves on its outer surface that act as mixing structures. Thus, when hydrogen is introduced into the adapter housing it is mixed with ambient oxygen within the chamber as it flows over the plug. The mixing structures in the housing creates a vortexing action as the hydrogen flows over the plug and towards the cylinder of the engine. An electrode protrudes from the plug towards the cylinder. The electrode is preferably platinum and generates the necessary spark to create combustion of the hydrogen/air mixture adjacent to the cylinder to thereby power the cylinder in the engine. A platinum electrode is preferably used because it enhances a catalytic conversion of combustion by-products to more environmentally compatible products. The present invention also teaches a spark plug producing a hotter spark for a hydrogen fuel system. Also taught is a hydrogen powered vehicle with reduced emissions by producing a spark during the power stroke and the exhaust stroke. Methods for reducing exhaust pollution are also taught. Methods of reducing exhaust pollution by generating a plasma are taught as well.

HYDROGEN POWERED VEHICLE, INTERNAL COMBUSTION ENGINE, AND SPARK PLUG FOR USE IN SAME

This application is a continuation-in-part of U.S. patent application Ser. No. 08/905,862 filed Aug. 4, 1997 by Herman P. Anderson, entitled "Fuel System For Internal Combustion System And Adapter For Use In Same" , now U.S. Pat. No. 5,852,993. U.S. patent application Ser. No. 08/905,862 is hereby incorporated herein by reference.

BACKGROUND OF THE INVENTION

The present invention relates generally to a fuel system for internal combustion engines that enables the invention to utilize alternative fuels; and, more particularly to an improved fuel system for an internal combustion engine and an adapter and spark plug for use in same.

The problems of air pollution caused by automobiles, lawn mowers and other vehicles that have internal combustion engines powered by gasoline is well documented. This problem is particularly described in an article in the San Diego Union Tribune, Wednesday, Sep. 25, 1996 and in Popular Science, August 1996. Indeed, under the Clean Air Act, in the next few years cars that do not run on standard fossil fuels like gasoline will be required in several states. Currently, there are no vehicles available to meet this need.

Thus, it will be appreciated by those skilled in the art that there has been a push to seek other fuels for use in internal combustion engines. These fuels include methane, propane and gasohol.

Hydrogen has also been characterized as a promising fuel source. See Department of Energy publication entitled "Hydrogen Fuel", printed in 1978, U.S. Government Printing Office, U.S. Department of Energy, Office of Public Affairs, Washington, DC 20585. Particularly, the graph presented in FIG. **6**, which is copied from this publication, shows the potential for hydrogen in BTUs/Lb. However, the mass energy density for hydrogen is low; and thus, hydrogen needs to be compressed before its energy potential can be realized. Hydrogen is a "dry fuel" that is more difficult to ignite than "wet fuels." It becomes more difficult to ignite when it is cooled. However, cooling is preferred in most systems to avoid premature ignition of the fuel. Other systems deliver the hydrogen under pressure to prevent ignition in the supply line, which is a form of pre-ignition. No prior art fuel system has been able to capture the energy of hydrogen.

Several fuel systems for use with hydrogen have been proposed. Examples are described in U.S. Pat. Nos. 4,167,919; 4,253,428; 4,016,836; 4,178,882; 5,222,993; 5,085,176; and 5,085,176. The problem with these prior art fuel systems is they cannot take advantage of the alternative fuels to generate sufficient power from the fuels to drive an internal combustion engine for use in a lawn mower, automobile or other vehicle. As noted above, this is a particular problem when hydrogen is used as a fuel. Additionally, the prior art systems do not address the problem of back fire, i.e. undesired explosion of the fuel in the cylinder during the exhaust stroke of the internal combustion engine.

Premature ignition or backfire is often a problem with hydrogen fueled systems. U.S. Pat. No. 4,383,198 (Hosking) teaches a fuel injection spark plug with a pre-cooling chamber to avoid premature ignition indentination of a gaseous fuel supplied to the spark plug. U.S. Pat. No. 4,383,198, Hosking, entitled "Fuel Injection Spark Plug", issued May 10, 1983, is hereby incorporated herein by reference. However, cooling hydrogen makes it more difficult to ignite. This is because hydrogen is a dry fuel whereas gas is generally considered a wet fuel. Thus to reduce fuel pollution one prefers to utilize a fuel such as hydrogen and ignite it with a hotter spark.

One patent discussing very high energy (VHE) ignition systems is U.S. Pat. No. 5,207,208 issued to Ward, entitled "Integrated Convertor High Power CD Ignition", issued May 4, 1993. U.S. Pat. No. 5,207,208 is hereby incorporated herein by reference. Pat. '208 teaches very high energy ignition systems, for instance on the order of 36K volts. It teaches voltage doubling utilizing pulsating sparks of peak current on the order of two amps. While 36K volts may at times be adequate, it is preferable to achieve a higher voltage in the ignition chamber when using hydrogen.

It is known in the art to use a direct ignition system, also referred to as a distributorless ignition system, to increase the spark plug voltage. Such direct ignition systems use a "waste spark" method of spark distribution. Each cylinder is paired with its opposing cylinder in the firing order (1-4, 2-3, on a four cylinder, 1-4, 2-5, 3-6 on a V6) so that one cylinder on compression fires simultaneously with its opposing cylinder on exhaust stroke. Since the cylinder on exhaust stroke requires very little of the available voltage to fire its plug, most of the voltage is used to fire the cylinder on the compression stroke.

U.S. Pat. No. 4,462,380 discusses a distributorless ignition system. U.S. Pat. No. 4,462,380 entitled "Enhanced Spark Energy Distributorless Ignition System" issued Jul. 31, 1984 by Asik is hereby incorporated herein by reference. Pat. '380 teaches a distributorless ignition system of an internal combustion engine which has a supplementary spark energy module to increase spark energy. Each high voltage terminal is connected to a single spark plug and each ignition coil primary is alternately energized and quickly de-energized, producing opposite polarity ignition voltages at each coil terminal. As a result, pairs of spark plugs are alternately fired, with each firing pair occurring in a compression or exhaust stroke and thereby providing the proper ignition to the engine. Asik asserts that firing a spark plug does not affect engine performance or emissions. As taught by the instant invention this is incorrect for hydrogen fuels when the exhaust is sparked at a sufficient voltage.

U.S. Pat. No. 5,146,882 (Brinkman) teaches use of specific wet fuel mixtures in conjunction with direct ignition systems (D.I.S.). It teaches that technical breakdown voltages for typical spark plugs are on the order of 15–20 kV and DIS typically yield between 30 kV–40 kV. U.S. Pat. No. 5,146,882, entitled "Method And Apparatus For Cold Starting A Spark Ignited Internal Combustion Engine Fueled With An Alcohol-Based Fuel Mixture", by Brinkman, et al., issued Sep. 15, 1992, is hereby incorporated herein by reference. The previously referenced prior art discusses alternate fuels and fuel systems but does not teach a method of achieving a sufficient voltage with a hydrogen system.

What is needed, then, is a fuel system for an internal combustion engine that provides a way to generate sufficient power from the alternative fuels and that reduces backfire problems. Such a system is lacking in the prior art. Also lacking in prior art is a system utilizing alternate fuels with reduced pollution capabilities. Also lacking is a way of generating sufficient voltage spark to ignite the alternate fuel.

The following U.S. Patents discuss spark plugs designed for gas internal combustion engines to reduce radio frequency noise and interference. U.S. Pat. No. 4,224,554, entitled "Spark Plug Having A Low Noise Lever" issued to Nishio et al., Sep. 23, 1980 is hereby incorporated herein by reference. U.S. Pat. No. 4,029,990 entitled "Spark Plug Construction" issued to Nagy et al., Jun. 14, 1977 is hereby incorporated herein by reference.

SUMMARY OF THE INVENTION

It is an object of this invention to provide an improved fuel system for use with alternative fuels.

It is a further object of this invention to provide an improved fuel system for use particularly with hydrogen, and particularly to enhance the mass energy density of hydrogen.

It is an object to provide a hotter sparking plug to ignite the fuel.

It is still a further object of this invention to provide an adapter for use in a fuel system for an internal combustion engine that enhances the power obtained from the alternative fuels.

It is still a further object of this invention to provide an improved fuel system for an internal combustion engine that does not present the environmental hazards of a standard gasoline engine by providing reduced or zero emission of environmentally harmful gases.

It is yet a further object of this invention to provide an improved fuel system for an internal combustion engine that can use an alternative fuel and can use gasoline to facilitate the transition from gasoline to alternative fuels.

It is yet a further object of this invention to provide an improved fuel system for an internal combustion engine that reduces backfire problems.

It is yet a further object of this invention to provide an improved fuel system for an internal combustion engine that reduces backfire problems by cooling the electrode in the spark plug with the hydrogen gas fuel.

It is an object to reduce backfire by providing hydrogen at a sufficient pressure to reduce backfire and igniting it with a hotter spark (i.e. a higher voltage).

It is still a further object of this invention to provide an adapter for use in a fuel system for an internal combustion engine that enhances the power obtained from the alternative fuels.

It is a further object to generate a plasma field in a cylinder to burn residual exhaust and reduce emissions.

It is yet a further object of this invention to provide a direct injection fuel system wherein fuel is injected directly into the cylinder.

It is an object to provide a "2-fire" direct injection system, wherein the fuel is ignited during the power stroke and the exhaust stroke.

It is yet a further object of this invention to provide a way to convert the standard induction fuel system of a lawnmower to a direct injection fuel system wherein fuel is injected directly into the cylinder.

It is yet a further object of this invention to provide a way to convert the indirect injection fuel system of an automobile to a direct injection fuel system wherein fuel is injected directly into the cylinder.

The internal combustion engine fuel system of this invention includes a structure for mixing the alternative fuel, preferably hydrogen, with oxygen in ambient air to stratify the fuel. The term "alternative fuels" is known in the art and is meant to refer to fuels other than conventional gasoline.

The invention in one embodiment comprises an adapter, the adapter including a housing mounted between spark plug and cylinder of the internal combustion engine. A plug is placed within the housing. The plug has ridges or grooves on its outer surface that act as mixing structures. Thus, when hydrogen is introduced into the adapter housing it is mixed with ambient oxygen within the chamber as it flows over the plug. The mixing structures on the plug create a vortexing action as the hydrogen flows over the plug and towards the cylinder of the engine.

An electrode protrudes from the plug towards the cylinder. The electrode is preferably platinum and generates the necessary spark to create combustion of the hydrogen/air mixture adjacent to the cylinder to thereby power the cylinder in the engine. A platinum electrode is preferably used because it enhances a catalytic conversion of combustion by-products to more environmentally compatible products.

Thus, the combination of the compression action generated by the conventional piston and push rod within the cylinder of the engine in conjunction with the hydrogen/air mixing structure that vortexes the hydrogen/air create compressed hydrogen that is mixed with a combustion facilitator, i.e. oxygen in the ambient air to enable the system of this invention to capture the abundant energy found in hydrogen fuel.

The enhanced mixing capabilities of this invention is also adaptable for use with other alternative fuels such as natural gas, alcohol, propane and the like.

One embodiment of the present invention is for a hydrogen powered vehicle including an internal combustion engine operably connected to power the vehicle and adapted to connect to a hydrogen supply line. The internal combustion engine comprises a cylinder operably connected to the supply line; a piston operably disposed in the cylinder; and a spark plug having an electrode assembly in operable sparking communication with the cylinder, wherein the spark plug is capable of producing a spark of at least 45 kV.

Preferably the spark plug comprises a housing having a sparking end and a hollow chamber containing the electrode assembly. The electrode assembly comprises an electrode having a connector end and a sparking end, wherein the sparking end is positioned adjacent to the housing sparking end. The electrode assembly preferably comprises a coil electrically connected to the electrode connector.

Preferably the housing comprises a fuel inlet port in fluid communication with the supply line, and an insulator surrounding the electrode assembly, wherein the insulator is positioned in the hollow chamber. Preferably the insulator comprises an outer surface defining a first fuel channel having a first respective fuel exit port, wherein the first fuel channel is in fluid communication with the fuel inlet port and the fuel exit port exits into the cylinder.

The present invention also includes a method of operating an internal combustion engine comprising supplying hydrogen fuel to the engine and creating a spark in the cylinder during the power stroke and the exhaust stroke, wherein the spark created during the power stroke is at least 45 kV. In one embodiment the spark is at least 70 kV. In certain embodiments the method comprises generating plasma during the exhaust stroke. The exhaust fuel converts to an exhaust emission and coalesces with the plasma, thereby reducing fuel pollution.

Accordingly, it is an object in the invention to provide a spark plug producing a sufficiently hot spark to ignite hydrogen fuel, including cooled hydrogen fuel.

Another object of the present invention is to provide a device for reducing fuel exhaust emissions.

Another object of the present invention is to provide a cleaner burning engine.

Another object is to provide a spark plug for reducing emissions.

Another object of the present invention is to provide a device functional with dry fuels. Use of the term hydrogen, as discussed herein, is intended to encompass such dry fuels. However the term as used excludes such wet fuels as gas and alcohol.

Another object of the present invention is to provide an integrated fuel system adapted to provide these and objectives.

Other objects and advantages of the present invention will be apparent to those of skill in the art by reference to the teachings disclosed herein, including the attached drawings, detailed description of exemplary embodiments, and claims.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1** is a plan view of the fuel system of this invention with a lawn mower shown in phantom.

FIG. **2** is a perspective view of the adapter of the fuel system of this invention.

FIG. **3** is an exploded perspective view of the adapter of the fuel system of this invention.

FIG. **4** is a cross-sectional view of the adapter of the fuel system of this invention.

FIGS. **5A–5D** are a schematic of the 4 cycle combustion in an internal combustion engine including the adapter of this invention.

FIG. **6** is a graph which shows the energy potential for hydrogen in BTUs/Lb.

FIG. **7** shows a vehicle of the present invention utilizing hydrogen fuel.

FIG. **8** depicts an intake stroke of a cylinder connected to a hydrogen source.

FIG. **9** depicts a compression stroke of a cylinder connected to a hydrogen source.

FIG. **10** depicts a power stroke of a cylinder connected to a hydrogen source. The spark plug shown in FIG. **10** is depicted sparking.

FIG. **11** depicts a cylinder in an exhaust stroke connected to a hydrogen source, wherein the spark plug is sparking during the exhaust stroke.

FIG. **12** shows an elevated side view of a spark plug of the present invention.

FIG. **13** shows a plan view in the direction of view line **13—13** of the spark plug shown in FIG. **12**.

DESCRIPTION OF THE PREFERRED EMBODIMENT

Referring now to the drawings, wherein like reference numerals refer to like parts throughout, the fuel system is referred to generally at **10**. The fuel system of this invention is contemplated for use with an internal combustion power system, such as an internal combustion engine or such as a home heating system. Fuel system **10** is portrayed in this case as connected to a standard lawn mower. The lawn mower is shown in phantom at **12** in FIG. **1**. The lawn mower is a conventional lawn mower as can be purchased from a company such as Murray of Ohio. The internal combustion engine in the lawn mower is a standard 4-cycle engine with two cylinders and develops 18 horsepower. A suitable example can be purchased from Briggs & Stratton, Milwaukee, Wis. 53201.

Referring particularly to FIG. **1**, system **10** includes fuel tank **14** that is mounted to lawn mower **12** via mounting assembly **15**. In the preferred embodiment, fuel tank **14** includes hydrogen gas. Accordingly, for the purposes of the foregoing detailed description, hydrogen gas will be described.

A line **22** begins at fuel tank **14** and proceeds to back-flow valve **16**. Back-flow valve **16** is a standard valve and is available from AirCo Gases Company, 575 Mountain Avenue, Murray Hill, N.J. 07974, part no. WCS CV-4M. PSI tank gauge **19** is inserted in line **22** between back-flow valve **16** and flow pressure gauge **18**. PSI tank gauge **19** is available from AirCo Gases Company also, part no. WCS CV5M, and serves as an indicator of fuel remaining in the tank **14**. Flow pressure gauge **18** is used to monitor the flow of the hydrogen in pressure units. The flow is started using valve **16**. The optimal flow pressure is 25 pounds of flow pressure from the tank **14** to the cylinder of the engine.

The flow of hydrogen is regulated via valve **20** that is part of gauge **18**. Thus, when valve **20** is opened, hydrogen proceeds through line section **22** to hydrogen flow solenoid **26A**. The user can access the hydrogen fuel by flipping hydrogen flow switch **24A** into the "on" mode so that hydrogen gas in line **22** can proceed through hydrogen flow solenoid **26A** and into line section **28**.

Throttle **30** regulates the flow of hydrogen from line section **28** into line section **29** and ultimately, to engine **13**. Throttle **30** is connected to throttle pedal **50** via includes throttle cable **48**. Throttle pedal **50** also operates the butterfly valves in the carburetor in engine **13** in a conventional manner.

As an option, the throttle can be controlled electronically by a digital fuel controller product. Such a product is commercially available from Autotronic Controls Corp., 1490 Henry Brennan Drive, El Paso, Tex. 79936.

Line portion **29** proceeds through splitter **32** and is split into upper line **34** and lower line **36**. Lines **34** and **36** proceed to adapters **38**. Additional back-flow prevention valves **39** and **41** are mounted between lines **34** and **36** and adapters **38**. Braided Teflon® is the preferred material for the fuel lines of the system.

Battery **42** is connected via battery cable **43** to magneto **44**. Magneto **44** then controls the current through spark plug lines **46** to adapters **38** in a conventional manner. Thus, the regulation of the spark that ignites the fuel in the cylinder of engine **13** is conventional. Additionally, the intake of air into the engine **13** is accomplished through the standard carburetor system of engine **13**. In a car, the sparking of the spark plugs can be controlled by the standard distributor/battery ignition system.

A second solenoid **26**B controls the flow of gasoline from tank **23** through gasoline line **52**. Solenoid **26**B is controlled by switch **24**B. Throttle **30** is connected to gasoline line **52** and can also be used to control the flow of gasoline to engine **13**. Thus, this invention can be used with both an alternative fuel and gasoline.

Referring now to FIGS. **2**, **3** and **4**, the adapter **38** of this invention is shown in more detail. Adapter **38** includes housing **60**. A threaded port **62** is formed into housing **60** through port block **64**. Hydrogen lines are threadably connected to the adapter **38** via port **62**. Port **62** is also referred to as an entrance port. The entrance port has an entrance area **62***a*.

Adapter **38** also includes spark plug **66** which is effectively a standard spark plug except for the modification to the electrode as described below. Spark plug **66** includes a threaded end **68** which is threadably received in the threaded upper end **70** of housing **60**. Spark plug wires **46** (as seen in FIG. **1**) are connected to connector end **72** of spark plug base **66**.

Electrode **76** protrudes from spark plug **66** and is of a length sufficient so that the threaded tip **77** (best seen in FIGS. **3** and **4**) of the electrode **76** is proximate to the cylinder of the internal combustion engine when the adapter **38** is mounted. In one embodiment the electrode **76** is coterminus with an exit port **88** of the adapter **38**. This most clearly is shown in FIG. **4**. Electrode **76** is preferably platinum to enhance catalysis of combustion by-products, as will be more fully discussed below.

Adapter **38** also includes plug **79**. Plug **79** includes an axial internal void space **80**. Thus, plug **79** fits over electrode **76** via internal void space **80**. Plug **79** preferably comprises a ceramic material that acts as a good insulator. A suitable source for ceramic plug **79** is AM/PRO Machinery, Inc. 134 Church Street, Plain City, Ohio 43064-1321.

An important aspect of this invention is found on the external surface of plug **79**. An annular groove **82** is formed on the surface of plug **79** near its distal end **81** so as to be proximal to the port **62** where hydrogen enters housing **60**. Two stratifying grooves **84** proceed along the surface of plug **79** until they reach its distal end **83**. It is these mixing structures, i.e. annual groove **82** and stratifying grooves **84**, that facilitate the improved power generation from alternative fuels as provided by this invention. It will be apparent to those skilled in the analogous arts that mixing structure may be formed in the inner surface of the adapter housing **60**.

Alternatively a combination of vortex producing structures is integral with both the plug **79** and adapter housing **60**. Also any conventional vortex producing means should be sufficient groves, per se, are not required.

On threaded tip **77** of electrode **76**, there are mounted a spacer nut **78** and a spark gap nut **85**. As best seen in FIG. **2**, the spark gap nut **85** includes a protrusion **85***a* that provides the spark gap between electrode **76** and periphery **89** of the exit port **88** of housing **60**. The exit port **88** includes an exit area **88***a*. Preferably, the exit area **88***a* is no larger than the entrance area **62***a*, though this is not critical. Preferably, the spark gap nut **85** is brass and the preferred spark gap distance is $^{25}/_{1000}$ of an inch. Of course, the electrode may be coterminus with the plug distal end **83**.

As best seen in FIG. **4**, where arrows represent gas flow, hydrogen gas flows into chamber **60** via port **62**. The hydrogen gas cools electrode **76**, which facilitates combustion. Stratifying grooves **84**, preferably there are two, act to mix the hydrogen that is flowing into housing **60** with ambient air therein. Though more or less vortex creating grooves (stratifying grooves) may be desired. Typically this will depend on the relative dimensions of the grooves and diameter of the plug as well as the pressure or velocity of the mixture in the housing. The mixing occurs within void space **86** of housing **60** and creates a vortexing or tornado action. Plug **79** tapers as it proceeds from its distal end **81** to its proximal end **83**. Thus, proximal end **83** is smaller in diameter than distal end **81**. This provides additional space within void space **86** for the mixing of the hydrogen and air. The stratified hydrogen/air are twisting in a vortex fashion when leaving housing **60** via exit port **88**. The vortexing action produced by grooves **84** on the plug **79** creates a "tornado" **110** of hydrogen/air with a hollow center that generates a vacuum. Similar effect would result were t he grooves to be placed on the housing. The vacuum propels the hydrogen/air mixture into the cylinder of the engine for combustion. Such mixing cannot be accomplished in a conventional induction system.

Referring now to FIG. **5**, a schematic of the system of this invention is portrayed, with arrows representing gas flow. Hydrogen flows in through port **62** through adapter **38** and into cylinder **92**. Air enters cylinder **92** through air intake **90** and air intake valve **91**. The stratified hydrogen/air mixture is compressed in the compression stroke of the engine via piston **94** and push rod **96**, which are standard structures in an internal combustion engine. In the power stroke shown in FIG. **5**-C, a spark is generated in the compressed stratified hydrogen/air mixture ignites and drives piston **94** and push rod **96** to power the engine.

The mass energy density of hydrogen is enhanced through the increased pressure on the hydrogen exerted by piston **94** on the hydrogen/air mixture within the cylinder **92** in the uptake stroke in an internal combustion engine. The pressurized and well-mixed hydrogen/air mixture is rapidly ignited through the spark because hydrogen has a fast flame front. This reduces problems with timing. Thus, the energy store found in hydrogen is captured through this system via the compression of the hydrogen gas within cylinder **92** and via the thorough mixing of hydrogen and air provided by adapter **38**.

In addition, in the exhaust phase in a four cycle engine a second spark is generated from the plug to ensure complete combustion of by-products. This is enhanced by using an electrode made of platinum. Exhaust leaves cylinder **92** through exhaust port **98**. Exhaust port **98** is closed during other phases by exhaust outlet valve **100**.

In the exhaust stroke, because air valve **91** is closed, the substantial component of the gases in cylinder **92** is hydrogen. This is also accomplished due to the fact that in the system of this invention, the hydrogen is continuously flowing. When this spark interacts with what is predominately hydrogen, a plasma is formed. This plasma blocks back-flow of air from exhaust port **98**. Prevention of back-flow of air prevents the hydrogen fuel system from backfiring, which is another common problem of hydrogen fuel systems. In effect, then, the plasma formed by the hydrogen acts as a virtual valve in that the plasma blocks the back-flow of air.

When the plasma of the hydrogen is generated as described above, UV radiation is generated which also facilitates consumption of combustion by-products. This increases the environmental friendliness of the system.

In addition to hydrogen the following fuels can be used in this system: natural gas; alcohol; gasohol; propane and buthane. A mixture of hydrogen and natural gas can also be used. As noted above, gasoline can be used in this system when solenoid **26** is used to stop the flow of hydrogen.

Further, it is contemplated that an adapter that is described herein for use with an internal combustion engine can also be used with a home heating system such as a home heating system that may currently use natural gas. The vortexing action created by the plug would enable appropriate power to be captured from the hydrogen fuel so as to effectively heat a home.

Another embodiment of the invention is a hydrogen powered vehicle **200** shown in FIG. **7**. The hydrogen powered vehicle **200** includes an internal combustion engine **210** operably connected to power the vehicle **200** and adapted to connect to a hydrogen supply **212** through a supply line **214**.

Referring to FIG. **8**, the internal combustion engine **210** comprises a cylinder **92** operably connected to the supply line **214**. A piston **94** is operably disposed in the cylinder **92**. A spark plug **216** having an electrode assembly **218** (not shown in FIG. **8**) is in operable sparking communication with the cylinder **92**, wherein the spark plug **216** is capable of producing a spark **220** (shown in FIG. **10**) of at least 45 kilovolts. FIGS. **8**–**11** are substantially similar to FIGS. **5A**–**5D** depicting schematic representations of a 4-cycle piston-cylinder engine. Other piston and cylinder embodiments will be apparent to those with skill in the art. FIG. **8** represents an intake stroke. FIG. **9** depicts a compression stroke. FIG. **10** depicts a power stroke, in which the spark plug **216** sparks. FIG. **11** depicts an exhaust stroke, where the spark plug **216** is sparking. Refer to FIGS. **5A**–**5D** discussed earlier for further description of similar components of FIGS. **8**–**11**.

FIG. **12** shows one embodiment of the spark plug **216** in an elevated side view. FIG. **13** shows a plan view of the spark plug **216** along line **13**—**13** shown in FIG. **12**. FIG. **14** shows a plan view of the spark plug **216** in the direction of line **14**—**14** shown in FIG. **12**.

FIG. **15** depicts a section view of the spark plug **216**. FIG. **15**, section view, depicts a representative spark plug **216**. The spark plug shown in FIG. **15** comprises a housing **222** having a sparking end **224** and a hollow chamber **226** containing the electrode assembly **218**.

FIG. **16** depicts the electrode assembly **218** removed from the hollow chamber **226**. The electrode assembly **218** depicted in FIG. **16** comprises an electrode **228**. The electrode **228** has a connector end **230** and a sparking end **232**. As shown in FIG. **15** the sparking end **232** of the electrode **228** is positioned adjacent to the housing sparking end **224**. The electrode assembly further comprises a coil **234** electrically connected to the electrode connector end **230**.

Referring to FIGS. **10** and **11**, wherein the piston **94** moves through a power stroke in FIG. **10** and an exhaust stroke in FIG. **11**, the spark plug **216** is shown to fire during the power stroke and the exhaust stroke.

The electrode assembly **218** shown in FIG. **16** comprises a steel ball **236** positioned between the coil **234** and the electrode connector end **230**. Other operable ball-coil-electrode arrangements will be apparent to those of skill in the art.

The spark plug **216** shown in FIG. **15** also comprises an insulator **238** surrounding the electrode assembly **218** and positioned in the hollow chamber **226**. A ceramic pore **240** is shown stabilizing the insulator **238** in the hollow chamber **226**. Other methods of locating the insulator in the hollow chamber will be apparent to those of skill in the art.

An elevated section view of the housing **222** is shown in FIG. **17**. An elevated side view of the housing **222** is shown in FIG. **18**. In the exemplary embodiment of the housing **222** shown in FIG. **18**, the housing **222** comprises a fuel inlet port **242** in fluid communication with the supply line **214** (not shown). FIG. **19** depicts an exemplary embodiment of the insulator **238**. The insulator **238**, shown in FIG. **19**, comprises an outer surface **244** defining a first fuel channel **246** having a first respective fuel exit port **248**. The first fuel channel **246** is in fluid communication with the fuel inlet port **242**. The fuel exit port **248** exits into the cylinder **292**.

FIG. **20** shows a plan view of the insulator **228** shown in FIG. **19** along line **20**—**20**. FIG. **21** shows a section view of the insulator **228** shown in FIG. **19** viewed along section line **21**—**21**. FIG. **22** depicts a bottom plan view of the insulator **228** shown in FIG. **19** along line **22**—**22**. FIG. **23** shows a section view of the insulator **228** cut through section line **23**—**23** shown in FIG. **19**.

In the embodiment of the insulator **228** shown in FIGS. **19**–**22**, the insulator outer surface **244** defines a plurality of fuel channels **250**, including the first fuel channel **246**. The fuel channels **250** include a plurality of respective fuel exit ports **252**, including the first fuel exit port **248**. This is shown clearly in FIG. **22**. Preferably, the plurality of fuel channel exit ports **252** are spaced equally, or equi-distant, about the electrode **228**. This is shown well in FIGS. **21** and **22**.

Referring to FIGS. **15** and **17**, one embodiment of the housing **222** sparking and **224** comprises a torridal ground electrode **254** positioned about the electrode sparking end **232** (shown in FIG. **15**). Preferably the housing sparking end **224** and the electrode sparking end **232** are co-terminous. In one embodiment the first respective fuel exit port **248** is co-terminous with the housing sparking end **224** and the electrode sparking end **232**.

More generally the present invention includes an internal combustion engine **210** adapted to operate on hydrogen fuel supplied through a supply line **214**. Typically the engine comprises a first cylinder **92** in fluid communication with the supply line **214**; a first piston **94** disposed in the first cylinder **92** to move through a power stroke and an exhaust stroke (See FIGS. **10** and **11**) in the first cylinder **92**. The engine **210** also comprises a spark plug **216** having a housing **222** including a sparking end **224** and an electrode assembly **218** located in the housing **222**, wherein the sparking end **224** is in operable communication with the cylinder **92** and capable of producing a spark **220** of at least 45 kV. Preferably, the spark plug **216** fires during the power stroke and the exhaust stroke. In one embodiment the housing sparking end **224** comprises a torridal ground electrode **254**. The electrode assembly **218** comprises an electrode **228** having a sparking end **230** capable of sparking toward the torridal ground electrode **254**. Preferably the electrode assembly **218** comprises a coil **234** in electrical communication with the electrode **228**.

In one embodiment the electrode assembly **218** comprises an electrode **228** having a sparking end **230** and a coil **234** electrically connected to the electrode **228** opposite the electrode sparking end **230**. This is the embodiment shown in FIG. **15**. Typically the spark plug **216** comprises an insulator **228** surrounding the electrode assembly **218**. Preferably the insulator **228** includes a fuel channel **246** having a fuel exit port **248** near the electrode sparking end **232**.

It will be apparent to those with skill in the art that the present invention also comprises a method of operating an internal combustion engine **210** comprising the steps of supplying hydrogen fuel to the engine **210**; moving a piston **94** in a cylinder **92** through a power stroke and an exhaust stroke; creating a spark **220** in the cylinder **92** during the power stroke and the exhaust stroke, wherein the spark created during the power stroke is at least 45 kV; and supplying the fuel to a location sufficiently near the spark to ignite the fuel. This is shown well in FIGS. **10**, **15** and **19**.

The present invention also includes a method wherein the step of creating a spark **220** comprises passing an electric current (not shown) through an electrode assembly **218** including a coil **234** electrically connected to an electrode **218** having a sparking end **232**; insulating the electrode assembly **218**; and arcing the electric current from the electrode sparking end **232** to a ground electrode **254**. The ground electrode **254** as shown in FIGS. **15** and **17** a toroidal ground electrode **254**.

In certain embodiments the step of creating a spark **220** includes creating a spark **220** having at least 70 kV. Creating a spark of sufficient voltage will generally reduce the exhaust pollution. Typically this happens by generating a plasma or plasma field during the exhaust stroke. Thus, one method of the present invention further comprises the steps of generating plasma during the exhaust stroke; and allowing exhaust fuel converted to an exhaust state to coalesce with the plasma. This reduces exhaust pollution.

Thus, the apparatus and system of this invention provides an effective means to use alternative fuels. The use of alternative fuels can enhance the environment by reducing the use of conventional gasoline and the environmentally detrimental by-products caused by the consumption thereof.

Thus, although there have been described particular embodiments of the present invention of a new and useful "Hydrogen Powered Vehicle, Internal Combustion Engine, And Spark Plug For Use In Same", it is not intended that such references be construed as limitations upon the scope of this invention except as set forth in the following claims. Further, although there have been described certain dimensions used in the preferred embodiment, it is not intended that such dimensions be construed as limitations upon the scope of this invention except as set forth in the following claims.

What is claimed is:

1. A hydrogen powered vehicle including an internal combustion engine operably connected to power the vehicle and adapted to connect to a hydrogen supply through a supply line, the internal combustion engine comprising:

a cylinder operably connected to the supply line;

a piston operably disposed in the cylinder;

a spark plug having an electrode assembly in operable sparking communication with the cylinder, wherein the spark plug is capable of producing a spark of at least 45 kV, the spark plug including:

a housing having a sparking end and hollow chamber, the housing including a fuel inlet port in fluid communication with the supply line;

an electrode assembly, received in the hollow chamber and including an electrode having a connector end and a sparking end, the sparking end positioned near the housing sparking end;

an insulator surrounding the electrode assembly and positioned in the hollow chamber,

the insulator including an outer surface defining a first fuel channel having a first respective fuel exit port, wherein the first fuel channel is in fluid communication with the fuel inlet port and the fuel exit port exits in the cylinder.

2. The apparatus of claim **1**, wherein the piston moves through a power stroke and an exhaust stroke in the cylinder, and the spark plug fires during the power stroke and the exhaust stroke.

3. The apparatus of claim **2**, wherein:

the spark plug comprises a housing having a sparking end and hollow chamber containing the electrode assembly; and

the electrode assembly comprises an electrode having a connector end and a sparking end, the sparking end positioned adjacent to the housing sparking end and the electrode assembly further comprises a coil electrically connected to the electrode connector end.

4. The apparatus of claim **1**, wherein the electrode assembly comprises a steel ball positioned between a coil and the electrode connector end.

5. The apparatus of claim **3**, wherein the insulator outer surface defines a plurality of fuel channels, including the first fuel channel, wherein the fuel channels include a plurality of respective fuel exit ports, including the first respective fuel exit port.

6. The apparatus of claim **5**, wherein the plurality of fuel channel exit ports are spaced equally about the electrode.

7. The apparatus of claim **6**, wherein the housing sparking end comprises a toroidal ground electrode positioned about the electrode sparking end, and wherein the housing sparking end and the electrode sparking end are co-terminous.

8. The apparatus of claim **7**, wherein the housing sparking end comprises a toroidal ground electrode positioned about the electrode sparking end, and wherein the housing sparking end, the electrode sparking end, and the first respective fuel exit port are co-terminous.

9. An internal combustion engine adapted to operate on hydrogen fuel supplied through a supply line, the engine comprising:

a first cylinder in fluid communication with the supply line;

a first piston operably disposed in the first cylinder to move through a power stroke and an exhaust stroke in the first cylinder;

a spark plug having housing including a sparking end, and an electrode assembly located in the housing, wherein the sparking end is in operable communication with the cylinder and capable of producing a spark of at least 45 kV; and wherein

the spark plug fires during the power stroke and the exhaust stroke;

the spark plus comprises an insulator located in the housing around the electrode assembly;

the housing comprises a fuel inlet port in fluid communication with the supply line; and

the insulator includes a first fuel channel in fluid communication with the fuel inlet port, the first fuel channel having a respective first fuel exit port exiting into the cylinder.

10. The device of claim **9**, wherein the housing sparking end comprises a toroidal ground electrode, and wherein the electrode assembly comprises an electrode having a sparking end capable of sparking toward the toroidal ground electrode.

11. The device of claim **10**, wherein the electrode assembly comprises a coil in electrical communication with electrode.

12. The device of claim **11**, wherein the electrode sparking end, the toroidal ground electrode, and the first respective fuel exit port are co-terminus.

13. The device of claim **12**, wherein:

the electrode assembly comprises an electrode having a sparking end, and a coil electrically connected to the electrode opposite the electrode sparking end.

Hermann Plauson

Hermann Plauson was an Estonian professor, engineer and inventor. Plauson investigated, among other things, the production of power based on atmospheric electricity.
Biography

Plauson was the director of the Fischer-Tropsch "Otto Traun Research Laboratories" in Hamburg, Germany during the Weimar Republic of the 1920s. He built on Nikola Tesla's idea for connecting machinery to the "wheelwork of nature". Plauson's patent no. 1540998 describe methods to convert alternating radiant static electricity into rectified continuous current pulses. His systems mainly involved needle & radium- coated electricity conducting balloons or aerostats which were connected to complex converting systems consisting of coils, capacitors, spark gaps etc. He developed an electrostatic generator called Plauson's converter. In 1920, Plauson published a research journal on the subject, titled "Production and Utilization of the Atmospheric Electricity" (Gr., Gewinnung und Verwertung der Atmosphärischen Elektrizität). A second, expanded edition of his journal was published later the same year. A copy of that edition is in the British Library at shelf mark 8754.b.36. A copy is also available in PDF-format, complete with Optical Character Recognition, through the books2ebooks service, here.

It is believed that Plauson was related to Gertrud Plauson (the exact relationship is unknown; she may have been his wife)...

Use of Beta-rays and X-rays in Synthesizing Liquid Hydro-carbons From Gaseous Compounds

Liquid hydrocarbons are synthesized by subjecting gaseous carbon compounds; such as are contained in water gas, coke oven gas, natural gas and gases produced by cracking heavy oils, to the action of rapidly moving electrons (#-rays) or the joint action of #-rays and X-rays. The reaction may be assisted by rotating electric and/or electromagmetic field and by catalyst in suspension in the reacting gases. The velocity of the rays should exceed one half the velocity of light and is suitably 200,000 to 260,000 kilometres per sec. The gases after exposure to the rays remain in a reactive condition the effect of which is obtained by circulating the gases under pressure. In addition to hydrocarbons, ketones, alcohols &c. are obtained particularly if the gases contain water vapour. Higher boiling point hydrocarbons may be obtained by subjecting those of lower boiling point to the radiations. According to an example water gas after subjection to radiations is compressed to 800-1000 atmospheres and maintained at this pressure for a time depending on conditions of radiation, temperature and the type of hydrocarbon to be produced. The hydrocarbon produced is mainly of saturated nature. The addition of ethylene, acetylene or other unsaturated hydrocarbons to the water gas shortens the process.

"Power from the Air". Science and invention (March 1922)

---

http://www.meridian-int-res.com/Energy/Atmospheric.htm

Historical Research

The leader in this field before the Second World War appears to have been Dr Hermann Plauson. Dr Plauson was an Estonian citizen who lived in Hamburg and Switzerland. He carried out experiments in Finland with aerostats manufactured from magnesium-aluminium alloy, covered with electrolytically deposited needles. The needles were further doped with a radium compound to increase local ionisation of the air. (This was the era in which the hands of watches were hand painted with radium to make them luminous in the dark). Zinc amalgam patches were also painted onto the aerostats. Plauson obtained a power output of between 0.72kW and 3.4kW from one and two aerostats 300m above ground level. Dr Plauson filed patents in the USA, Great Britain and Germany in the 1920s. His book "Gewinnung und Verwertung der Atmosphärischen Elektrizität" is the most detailed known account of the technology.

Other atmospheric electricity researchers contemporary to Dr Plauson included Walter Pennock and MW Dewey in the USA, Andor Palencsar in Hungary and Dr Heinrich Rudolph in Germany. Hippolyte Charles Vion in Paris predated them all, putting forward proposals in the 1850s and 1860s.

Heinrich Rudolph made an interesting contribution to the design of the aerostat collectors. In 1898 he designed an elliptical aerostat made up of faceted surfaces to minimise the effect of wind. The design bears a strong resemblance to Northrop's 2003 UCARS unamnned helicopter UAV project. The design uses the Coanda Effect to help keep the aerostat on station and minimise wind effects.

MIR's Research Programme

Since 1997 we have been carrying out theoretical research into conversion of atmospheric electricity into useable electrical power.

From a low level (5m high) simple zinc antenna we are able to obtain sufficient charge to light a number of white power LEDs. Further experimental investigations with metallic aerostat collectors and cavity resonant slow wave antennae concepts are ongoing.

A number of programmes are underway in developing countries to provide remote communities with LED lighting instead of conventional incandescent lighting. LEDs are a very efficient way to provide lighting for minimal electrical power requirements. Atmospheric electricity would be ideally suited to powering domestic LED lighting or low energy neon lighting.

There is every reason to believe from our experimental tests and earlier research by Plauson, Jefimenko and others that Atmospheric Electricity will be able to provide practically useful levels of electrical power particularly suited for off-grid applications in the developing world.

Advantages of Atmospheric Electricity

Simple and robust technology
Low Cost technology - much cheaper than photovoltaics or wind turbines
Available day and night in all weather conditions - in fact, more power is produced at night than during the day
Available at any point on the Earth's surface...

Gewinnung und Verwertung der atmosphärischen Elektrizität

Beitrag zur Kenntnis ihrer Sammlung, Umwandlung und Verwendung Mit 82 Figuren auf 22 Tafeln

HERMANN PLAUSON, Harmburg 1920

Vorwort.

Motto: Wem es gelang in ein Geheimnis der Natur zu dringen Und dies in Menschenpflicht der Menschheit darzubringen, Der betet die Natur und ihrer Wunder Fülle an.Verfasser.

Es ist schwierig und wenig dankbar, ein Buch über ‘ein Gebiet zu schreiben, das bis heute fast noch gänzlich unberührt ist.

Obwohl die Lehre über atmosphärische Elektrizität an und für sich schon in gewissen Kreisen bekannt und einigermaßendurchforscht ist, auch sogar einige theoretische Abhandlungen über dieses Gebiet geschrieben sind, so ist umgekehrt auf dem Gebiete der technischen Gewinnung, Umwandlung und Verwertung von atmosphärischer Elektrizität bis jetzt nochnichts bekannt. Es kann sogar festgestellt werden, daß einige Wissenschaftler eine Gewinnung und Verwertung deratmosphärischen Elektrizität in der Praxis überhaupt bestreiten.

Wenn nun trotzdem der Verfasser dieses Wagnis unternommen hat, so trieb ihn vor allen Dingen die außerordentlicheWichtigkeit der Lösung dieser Frage für die Menscheit hierzu und dann die auf Grund von Versuchen erhaltenepersönliche Überzeugung, daß bei Verwendung aller wissenschaftlichen Errungenschaften und Forschungsergebnisse derletzten Jahre auf dem Gebiete der atmosphärischen und statischen Elektrizität, bei Benutzung der Erfahrungen auf demGebiete der drahtlosen Telegraphie und Telephonie, wie der Erzeugung von ungedämpften Schwingungen überhaupt,ferner unter Zugrundelegung der Lehre über radioaktive’Erscheinungen und deren Folgen viel größere Energiemengengesammelt werden können, als bisher nach den theoretischen Berechnungen zu erwarten war, die auf Grund desnormalen, vertikalen Leitungsstromes gelten die Erde, sowie auf Grund der Gesamtladung der Erde angestellt wurden.

s wurde vom Verfasser festgestellt, daß dies erreiCht wird sowohl durch Erhebung voll metallischen Ballons mitradioaktiven Substanzen und elektrolytisch hergestellten Nadeln usw., als auch durch geeignete weitere Verwendung undVmwandlungsart dieses Stromes (Umwandlung statischer Elektrizität in mehr oder weniger hochschwingendedynamische) sowie durch Verwendung geeigneter Kondensatorenbatterien und dereff Einschaltungsweise und zuletztdurch geeignete Schaltungsschemata. Versuche ergabeff aber, daß noch zahlreiche neue Vorfragen zu lösen waren, und datl der Ausbau des Problems, Verwertung der atmosphärischen Elektrizität, auf ganz neuen Grundlagen erfolgen mußte. Der Verfasser hofft durch diese Schrift den Beweis zu erbringen, daß er auch dieses erreichtoder wenigstens die Wege dazu angegeben hat.

Das zweite Ziel des Verfassers ist, durch baldiges Erscheinen dieses Buches breite Kreise der Wissenschaft und Elektrotechnik fürdiese Frage zu interessieren, und durch die im Buche angegebenen Anregungen möglichst viele Mitarbeiter zu gewinnen.

Es sei ferner noch gesagt, daß das Buch nicht eine abgeschlossene Forschungsarbeit zu sein beansprucht, sondern vielmehr als ersterVersuch, als Wegweiser in der vorliegenden Frage zu betrachten ist. Es bleibt sowohl in der Schreibart als auch in der Anordnung desMaterials noch viel zu wünschen übrig, da das Buch zum Teil aus Patentschriften des Verfassers entstanden ist, zum Teil aus einemVortrag über atmosphärische Elektrizität, den der Verfasser vor einer Versammlung von Fachleuten gehalten hat, um den Bau einerMusteranlage zu propagieren.

Veranlaßt durch das rege Interesse größerer Kreise für diese Frage, läßt der Verfasser dieses Buch sich seinen Weg selbst bahnen undbittet, etwa infolge der Eile sich fühlbar machenden Mängeln gegenüber nachsichtig zu sein.

Bei der Zusammenstellung dieses Buches wurde folgende Literaturbenutzt:

Mache & Schweidler: “Die atmosphärische Elektrizität”Dr. I. Zenneck: “Elektromagnetische.Schwingungen und drahtlose Telegraphie”
Dr. M. Dieckmann: “Experimentelle Untersuchungen aus dem Grenzgebietzwischen drahtloser Telegraphie und Luftelektrizität”I. Teil Teil (Zeitschrift fÜr Luftfahrt und Wissenschaft,2. Heft).

Für Leser, die dieses Gebiet nicht völlig beherrschen oder Einzelhejten darüber wissen wollen, sei zum besseren Verständnis dieserAbhandlung empfohlen, vorgenanntes Werk: Mache & Schweidler .Die “atmosphärischeElektrizität”, VerlagVieweg & Sohn,Braunschweig, durchzulesen.

Es ist dem Verfasser zum Schluß eine angenehme Pflicht, Herrn H. Otto Traun für die ihm erwiesenen Unterstützungen seineDankbarkeit auch an dieser Stelle auszudrücken.

Ferner möchte der Verfasser nichtversäumen, Herrn Max Thorn zu danken für die erste Anregung, die gesammelten Erfahrungen undKenntnisse der Allgemeinheit nicht länger vorzuenthalten, und für die Bemühungen zur Finanzierung einer hoffentlich irn Jahre 1920 zu erbauenden Versuchsanlage, wodurch dieWichtigkeit dieses Problems irn Großen praktisch vor Augen geführt werden soll.

Schließlich spricht der Verfasser Herrn Dr.-Ing. Gerhard Schmitt und seiner Assistentin, Fräulein Gertrud Hildenbrandt,für freundliche Übernahme der Korrektur, sowie Herrn Ing. Hans Koop für Ausfertigung der Zeichnungen an dieser Stelleseinen wärmsten Dank aus.

Der Verlagsbuchhandlung sei für die anerkennenswerte Ausstattung des Buches und besonders für die guteAusführungder Figurentafeln hiermit der besondere Dank des Verfassers ausgedrückt.

Der Verfasser.

General part

The production and utilization of atmospheric electricity for the well-being and prospering of mankind is a goal of scholars and researchers; the implementation remained however until today a pious desire, and it did not succeed to somewhat really reach [WertvoJles] and for industrial purposes usable.

The cause for this is not to be looked for in the fact that the electricity freely available in atmospheric air is not to be exploited at all, but primarily in that the science before solution of this problem had to solve a set from preliminary questions to, by their clarifying only the possibility of an utilization of atmospheric electricity became at all conceivable.

Only in the last years their utilization could be made due to new experiences and investigations on that areas of the atmospheric electricity.

If we try many ages [zurückwand~rn] and to investigate the past according to data concerning atmospheric electricity then we must notice with being astonished the fact that nothing is new in the world that for a long time, for a very long time before the knowledge of the electricity at all admits the features of the atmospheric electricity was and that they, what appears still less [glaublich] were even used.

The knowledge of the effect and utilization of atmospheric electricity hand back already many thousand years, as we can infer from the holy writing. Thus we read all geweihten persons, with exception of the upper priest in the Bible Moses that the tabernacle in all-holiest of the temple Jehova possessed the power to kill when affecting by a thunderbolt or a fire. Furthermore we read that 40 priests had dared enter in the absence of Moses and Aaron, and that from the tabernacle lightning drove out, which killed all 40 priests. If we experience now far from the books of the kings the design of the new temple by king Salomon, then from the electrotechnical point of view can only come only to a conclusion that Moses and Aaron knew already at that time as one could collect an unknown godlike power from the tabernacle, as one had to [aurbewahren] the same, and as it worked, because of-today's point of view of the Wissenschart regarded the federal drawer can have been nothing else as a Leyden bottle or a condenser of very large capacity, which by means of arranged points was loaded with atmospheric electricity . The fact that the charge kept itself good and worked well is only the constant shop with atmospheric electricity to attribute as well as the dry climate in Palestine.

It comes out from the Biblical description that the ssundeslade out well isolationable noble wood had fitted made and also gold and such a thing from the inside and outside. Thereby all conditions were erffillt rur a good electrical condenser or a Leyden jar.

E.G. the gentleman writes the Moses forwards (2. Book Moses, Chap.25, verse 10-15)

Furthermore still is given the description of the building in the Chap.37-38. An electrical engineer could not make it better nowadays, wanted it follows a Leyden jar to build for the purpose, humans a [göttliche Kraft] the Ungeweihte to kill immediately can to lead before eyes or to pretend.

The charge of the federal drawer with atmospheric electricity in the all-holiest was obtained by many columns and golden points. In addition, the whole temple was, as from the description hervorgehl, provided with hundreds of gilded points, by presenting gold on zedern and acacia wood bars.

03

The fact that here really electrical discharges took place can do out following in 2. Book of the Chronicles, Chap.7, verse 3, described place to be taken DAuch saw falling down all children Israel the fire and the glory of the gentleman over the house, and fell to their knees, with the face to the earth and prayed on and thanked the sir, it good-naturedly are eternal and its mercy lich last. “People saw here the impact of lightning into the lightning conductor established on the temple. DI1ss the collection and Aufbewl1hrung of the atmospheric

Electricity much gefäh " to be rlich could, if someone did not understand with the federal drawer to deal, read 'we further in the 3. Book Moses, chapter 10, where the sons Aarons, Nl1dl1b and Ahibu wanted to bring, d~m Mr. Freudenfeuer, what the Mr. them not ordered hatteWir to read that a fire proceeded from the gentleman and it verzehrte, so that they died before the gentleman.

From everything it is evident that Moses were and its contemporaries the first connoisseurs and Ausnutzer of the atmospheric electricity. Were not natural them, how us, which admits to electrical laws separate only the effects of these mystischen Kraft. These features are probable the culturally more highly standing Egyptians even already admit been, and Moses may have bring along its knowledge of the priests from Egypt.

From this time to the attempts Frl1nklins with BJitz the production of atmospheric electricity made only small progress for arresters and Rimans attempts. With the study of the meteorology the large interest in the atmospheric electricity was again excited, and in the last 30 years several times the thought stepped to light to use it. Which was already done in this regard by other researchers, I try to describe in the connection hieran briefly, by lighting up this question I1m of best patents spent through in former times.

The first patent, that according to indication German realm Reich office, is that is given D.R.P. No. 98180 of the t9. January 1897. Inventor: Dr. Heinrich Rudolph in Stc Goarshausen A. RH. The Patentl1nspruch reads: Your by a kite chain balloon carried, from two steel tubes and many vertically stretched fine wires manufactured, large and nevertheless extraordinarily light net for the collection of atmospheric electricity together with for installing and for the acceptance of this net, occupied with needles I'rüher announced patents and their evaluation.

04

necessary mechanism, consisting of a number of posts with ever two axle camps and some small electric motors. “

Description.

Net for collecting atmospheric electricity.

The subject of available invention forms, with approximately 3.6 million needles an occupied, ungefäh~ 9 hectars large and net which can be held by a kite chain balloon in 1000~2000 rn heavy against 700 kg for height for accumulating atmospheric electricity together with the mechanisms erforderiichen for isolated derivative For the clarification of the state of affairs is emphasized that those.

For the clarification of the state of affairs is emphasized that those Franklin attempts the possibility of the derivative of atmospheric electricity for the earth long did that it concerns however with the voriiegenden invention particularly around the described mechanism, such, which suggests a commercially usable amount of energy of the derived atmospheric electricity. Which concerns the aids to the commercial utilization of the net described in being inferior, then is referred to the patent No. 98288 standing with available article in closest Zusammenhange. In the enclosed design a such net is together with the kite chain balloon in Fig. 1 in front view represented, Fig. a side view shows 2, while the Fig. 3-5 details represent.

A such net N (Fig. 1) can be manufactured by means of two ungerahr 300 rn long casting steel tubes R R, by 1 mm of wall thickness and 2 cm diameters, which will receive the same by Ineinanderschieben of individual pipes from production length and fastening by small steel pins with screwed on safeguard panels. These pipes are to form the two horizontal sides of the square net, between which about 1200 vertical bronze wires of 300 are to be stretched rn length and 0.04 qmm cross section in distances of 0,25 rn. Since rn much purifies the thin wires in distances of 0,1 and length sharpens needles of 1 cm carry must, then they are wound meanwhile before slowly on Rol) EN and the needles with the help of a springy eye open at their lower end are touched down. The eye must selbs (understandably the wire size so adapted to be that it wedges deQ wire and that the needles sit sufficient firmly. Also rolling up must happen sufficient loosely, so that the put on needles do not break. The main difficulty such a square network of 300 rn side length offers an installing and a removing the same, the whatever latter in Ausnahmerallen becomes necessary - can. Is necessary for it a number of man-high posts (p), in

05

Rn lineally and all two axle camps I are one behind the other set up to distances from 7 to 8 possess (Fig. 3). Built up on the same the two 300 rn are enough for Slahlrohre R R, and provided with the necessary hooks, by lelztere safeguard panels small by boreholes of the pipes put, and become screwed on!? n. Whereupon wires are to be stretched from Pfoslen to posts, on which the necessary number of roles with the needle-occupied bronze wires is. The ends of the same are raised to the hooks a Slahlrohres geknlipfl and the latter by the Fesselballon, which is to carry the net, so that the bronze wires of the roles complete themselves. So that the dlinne steel tube no bend experience, it is carried by 40 Gussslahldrähten, which hang on the hook for the chain cable and branch out toward their lower end three-way, so that they can be befesligt in distances of approximately 2.5 rn at the mentioned pipe. Dieseiben are in their length like that abzugleicheil that they form approximately an equal-leg triangle of 250 rn for height, whose basis is the pipe carried by them also they need to have only 1 qmm cross section against the center, during toward the ends of the pipe a Quersc--hnitt of 2 qmm necessarily isl.

If the needle-occupied bronze wires are completed, then they become to the zweile steel tube geknüpfl. After 31 bronze wires of 0,13 qmm Querschnilt without NadelQ, further on the opposite side of this pipe in distances of 10 rn, are beftlstigt for the derivative of the Elektrizilät, the net so because is lifted, until about 1000 rn the chain cable by the hoist of an anchor car it is completed, on which to the cable it fastens the bronze wires jointly but becomes only so loosely strained that the net down-hangs almost vertically, with its surface senkrechI the Windrichlung. If the net is to be removed again, then approximately in reverse way, only with the difference that thereby small electric motors at each second post step into activity, those will proceed by wheels with a removable Cutout, by which they can be touched down easily on the lower pipe, the latter in revolution to shift and the needle-occupied wires to the same to complete.

It can occur however the case that for the acceptance of the net in this way sufficient Zeil does not remain, if approaching storm with a larger wind force than 25 rn the rapid salvage of the Fesselballons behind a wind protection with the help of, the electrically operated Anke running on rails " rwagens makes advisable. Then \ ias net on a sufficient even must Place easily on the ground to be established,

06

similarly as one things materials in folds puts, then it could be lifted later again intact into air.

In order to be able to notice also a large wind force in 1000 to 2000 rn height with relative peace at the soil, a Federdynamometer put onable in any place without detachment of the chain cable must steadily the tension of the latter anteigen. If such a case of strong upper wind arises, then the bare short binding is naturally already sufficient to the safety device of the balloon and net

Which concerns the potential of the atmospheric electricity, then a potential gradient of 150 V for I is rn as always available to regard after numerous observations. For 1500 rn height would result in that 225000 V. If one wants to charge a battery with the received river from 20000 one behind the other switched accumulators, then it requires a charging voltage of 45-50000 V, for which straight still the isolation can be accomplished. From it a voltage drop of 175000 V in the environment of the net, which after the observations over the conductivity of air with grösserern potential gradient a sufficient river secures, results particularly due to the 3.6 million of fine points of the net and the constant continuation of the unloading air layers from the wind. So that the electricity collected by the net can be derived now in addition, isolated, about 100 rn a long silk rope T by sixfold security, which is protected from wetness by an india rubber casing, must be switched on, into the chain cable F, and, be led the electricity by a special cable G of 5 qmm for casting steel cross section and 2 qmm copper soul downward below the place, where the bronze wires are fastened to the chain cable.

While now the cable G after a well embodied, hollow iron mast M, is the chain cable leads to the electrically operated hoist Weines of anchor car fastened, which, according to kind the mobile crane with swivelling upper rack, provides jib and counterweight, on a circular rail gel ice with approximately 20 rn radius around the mentioned hollow mast to move can, so that it is able to follow each change of the wind direction. The jib of the anchor car serves to keep the lower horizontal part so high the Seilkurve described by the Fesselballon over that ground that it does not schJeift.

It is necessary that cables and chain cables are from each other distant in air always far for enough, in order to prevent an upper jumping of the high voltage stream. That is possible by a tauter tension of the easier Lejtungska~~ls. DeshaJb goes this, after it by a slip ring G carried by e1nem Olisolator is led, by an isolating india rubber pipe, by about 10 rn high mast down to a hand winch w present under oil, whose drum provided with steel axle is formed by porcelain or ebonite, so that one can with each change of the length of the chain cable for the case of zero wind or storm also the cable accordingly stop and again stretch

From the hollow mast M out the line goes underground through one. Channel up oil insulators under the gel ice for the anchor car away and then as high voltage air line after the battery station, which can be established also for several balloon stations together.

There a double battery of 20000 small accumulators each is to be set up, from which always a battery delivers river, while the other one is loaded. For this purpose one must be able to switch everyone one behind the other into approximately 300 groups at will neben¬ and. The accumulators must rest by groups on racks, which are carried by oil insulators.

From apparatuses are on a battery station except usual flat TAP-ready necessarily:

Erdschtuss with simultaneous interruption of the line to Battery.

Adjustable spark gap as Nebenstromkreis with ground fault to the announcement of interruptions.

fuses for the case of Kurzschi1uss of the battery.

Ammeter.

Pendulum electroscopes.

Electrostatic one dares to the innocuous making of line interruptions, by the same with exceed more eiper certain tension ground fault one manufactures and by a electromagnet in the ground conductor the line to the battery one interrupts. {In Fig. 4 is the electrostatic dare omitted.)

automatic commutator (Fig. 5) for the charging current, be standing from electromagnets (omitted in the design), which brings two levers with isolated connection to the

high voltage air line and to the earth with Poland the battery depending upon current direction in or to other sequence in connection.

The last device is particularly important for the utilization of the extraordinary, but sign after rapidly changing electrical tensions of the thunderstorm and heap clouds, that large Konduk gates and condensers of the atmospheric electricity.

By pie 3.6 million points of the net thereby the plant appears secured against each destructive spark discharge All apparatuses except 2, 4 " and 5 must have contacts from platinum and for preventing of sparking and fusion under oil are. All work on the high voltage transmission line before by means of laliger ebonite seaweeds ground fault is made, whereby for preventing of short-circuit the line must be interrupted at the same time to the battery thus the tension sinks on zero. On the balloon stations are necessary: the apparatuses I, 4, 5 and 6, the latters however without dare and only with electromagnet in that Ground conductor to the Unterbl echung (Fig.4). The Schienerigeleise must on. the ground conductor of the balloon station put its, füi' the case that once the cable puts over the anchor car or the chain cable affected.

If one takes now managing patent application under the magnifying glass of the criticism, then it must be stated that the Erfindungsgedanke for the following reasons cannot be lebensflihig:

The balloons must possess very large volume, since they are to carry d1e of large heavy nets and the strong rope. The latters must be strong, so that they are not torn up by the storm.

The expansion of such a plant over large surfaces - z. B. IQO qkm - is therefore: A) commercially impossible, because a great many balloons of this kind were needed, which would be enormously expensive, and B) practically not executably, because one cannot secure such large balloons in large heights sufficient before storm also the same, there made of things, ground very fast leaky. From it large dangers for humans, the result if such a balloon tear off and from leak from on earth fall, became a Kurzschussnt stand, the tremendous disaster, which death of many humans could entail.

For above reasons already this patent is not usable nevertheless is it interesting because of the attempt, which so collected electricity to the charge of a double battery of over 20000 small accumulators, from which the energy delivers, while the other one is loaded. Such a system would be the most ideal solution of the Transforming of atmospheric electricity into low tension usable for the technology. Because of the isolation difficulties it is however unfortunately impossible to load 20000 elements with approximately 50000 V 1 more user that the initial costs of the 40000 elements would be too expensive, completely apart from the fact that the maintenance of these batteries do not only require many people, but also with large danger for the supervision personnel it would be connected.

He same wants to obtain by the following patent claims:

procedures for the Nutzbarinachung of Atmospheric electricity, thereby characterized that the same by means of a be¬wegten, by a g~eignete HeizqueJ] e of catching body heated up it is caught and trans¬formiert by means of a rheostatischen machine, how to the charge of accumulators the Electricity thereby on constant Spal! nung to be held that the rheostatische Machine or a number of their plates is connected with a charge measurer (electrometer), that, as soon as dte rheostatische machine was loaded on a certain potential, knows by the excursion of its mobile part a contact closes, whereby, under switching of a relay, an electromagnet is perhaps brought to responding, the change-over of the rheostatischen machine effectuation

Device for the execution of the procedure, consisting of a double-walled LuftbaJ] on (1, ge¬kennzeichneten in requirement 1., 2), which by a MetaJ] net provided with needles is covered and when the Auf¬ and descending by tiltable shovels (9) in revolution one shifts, from a Hejz¬rohr (12), which is through tubes with upper and lower parts of the area (II), formed by the Dop~elwänden of the balloon, connected, aus' mjt the wire net in leading Ver¬bindung standing ball bearing (14), which with the taps des¬seiben leading connected cable (13), that with the KoJ] ek¬tor (17) provided winch (16) and the rheostatischen machine (18).

3. During the device characterized in requirement

2. the application of a Electromagnet, which is excited by a charge measurer (Elektro¬meter), connected with the rheostatischen machine, to the change-over of the rheostatischen machine, as soon as the potential achieved the same in-certain measure ".

Patent specification:Procedure and device for catching atmospheric electricity

Available invention trilft a procedure and a device for catching and deriving atmospheric Electricity, which make it possible, larger quantities of the same in usable: to receive it form.

The Erfindungsgedanke is based on your theory of the atmospheric electricity, after the the same by the condensation of

10

One forms for water vapours. According to this theory now the water droplets floating in the air layers are to be regarded as carriers of the electricity, and a rational system of the derivative of the atmospheric electricity must the same now of the water droplets ab¬leiten. This is way-reached after available invention on the following

With pointed needles of provided catching bodies of mög lchst large surface becomes into higher air-laminated? moved, however by a suitable heating device continual warms up. By the heat water droplets become! dey the catching bodies directly surrounded, the capacity the same evaporates decreases aJI¬mählich, and thus the tension of the charge rises.

It is now easy evidently that the whole charge of the droplets, as soon as the same evaporated, on which catching body Über¬gehen becomes, from which it be derived can. U m however the evaporated and their charge robbed droplets by new and loaded to replace, becomes the catching body the surrounding enclosed design schematically represented, in Pig. 6 and 7 by the opinion and the cut of the catching balloon. Pig. the deriving device, Pig.9 the regulation device, pi shows 8! (. 10 and II a shovel in their two positions, Pig. 12 and 13 the circuit way of the rheostatischen machine in their two air in relative motion shifts. A remark example of the invention article is up positions.

The pre-adjust consists of a double-walled balloon I, 2, the light wire nets, favourably from aluminum wire, occupied with one with needles, covered is. The balloon carries also the net 3, on which the ring 4 made from firm, but light material (wood, pipe etc.) is fastened. The latter carries the basket 6 by means of the cords 5. In the level of the ring 4 still the ring 7, that is by those easily swivelling gelagenen shovels (9) spread and by dle cords 8 in its position held w! about SI haufeln of covered framework with light material, whose turn in both directions is limited by the notices 10, consists. The shovels form with the vertical one appropriately an angle from 60 to 70 degrees. All wire nets, cords, rings and shovels can be covered? with small Metallna'deln, which are connected among themselves leading. Of the area II fühn of the deepest point the pipe 26, formed by dje Doppel¬wände of the balloon, too, which in the 'basket 6 untergebrach1en coiled tube 12, which is again with your in the upper Tei, 1 of the intermediate area II connected to flowing pipe 13. The coiled tube: becomes by means of a suitable heating source it heats up whereby between the Dappelwänden of the balloon continual warm gases vein air flow rotates.

Under the basket with the wire nets leiiend ver¬bundene ball bearings 14 are attached, its tap with sorgi: iltig isolated, easy and sufficient is connected for firm cables 15 leading.

On the surface of the earth the hoist 16 (Fig.6) is, by means of which the balloon can be down-pulled and brought to the rise, as soon as the internal balloon with illuminating gas or hydrogen is gefüljt.

With the increase of the balloon the carried out over liquid work can be stored in any accumulator and be made usable with the Niederziehen of the balloon. The end of the cable core is at one at the axle of the hoist isoJiert attached collector firmly, from which the electricity is derived by means of a sliding contact. Collecting the electricity takes place by means of the fact that the balloon is down-moved by means of the hoist continual up and.

With this movement the balloon receives a turn, which will not change its sense by the shovels 9, since during the transition of the rise to sinking the balloon or turned around the shovels are tilted by air resistance, and therefore the balloon the turning movement in the same sense to give. In order to avoid here a turn of the cable, the ball bearing 14 is intended. The fact that the turn of the balloon takes place with on and descending in the same direction illuminates from the following.

The shovels 9 are easily swivelling, whereby the axis of rotation does not fall into the center line the same. Hierdl1rch places itself the shovel with the downward course of the balloon in in Fig. 10 drawn position, and der' balloon is from right to left turned. During the upward course the shovel tilts, b it the lower notice 10 limited (Fig. I). IE one sees, takes place the drive from above after air flow arranged downward again from left to right, the balloon can thus its direction of rotation maintained. By this up and Niederbewegen and tricks of the balloon the purpose that the same with as much as possible water particles floating in air into contact comes, is reached.

Of collector rings 17 derived electricity nJn a too high and much too much a changing tension possesses, in order to be able to be veaertet directly. Since one maintains accumulators too ladan and only the easily adjustable river with an irregular Elektrizitätsquelle first the same further used, then one must to the shop of the accumulators the electricity on more constant, derived from the collector 17, stretches! to receive lng. search and those

12

Tension also into belleutend a lower transform. Since one has to do it however in this Fa1le with a direct current, then usual transformers can not be used for this purpose. In addition the Electricity in this case possesses a much to large tension, so that when using common transformers the largest part of the collected electricity would come again into loss. 'The only applicable method is for this purpose the transformation by means of the planning ashes rheostaischen machine, by this high-tension electricity almost completely without loss transforj11iert will can. Thereby the question of the transformation would be solved only the preservation of the constant tension remains for more. This is reached in the following way:

Rheostatische machine 18 or only one part of the plates stands for the latter change-over of the rheostatischen machine with any charge measurer (electrometer) in connection, whose mobile part closes one, contact, what is caused, how the same unloaded. The potential sinks, and the ElektromeIer takes its initial position, whereby the Slrom umschailung the causative Elektromagnelen becomes interrupted and the P'atten of the rheoslatischen machine tension geschaltel. Then now to the erneulen charge ferlig and is again unloaded with the beslimmten tension. This play repeats itself continual, so long the apparatus in the enterprise stehl.

To the easier understanding the pattern of the rheoslatischen machine is indicated. Fig. the load position shows 12. The panel 42 is connected with the Fesselballon, while the last panel is led to the earth. Fig. the unloading position shows 13. In Fig. the rheostalische machine is drawn 8 in the load position, and that simplicity half is not the connection of the panel of 42 with that contacts 17 gezeichnt just like also the contacts for the unloading position (Fig. 13) is omitted.

With the elektrostalischen Schaltapparat' (Fig. 9) combined effect of the mechanism is the following:

The contact roller 27 (Fig.) always one brings to 9 by the feather/spring 37 into the load position. In addition axle a Electromagnet 35 is gekeilt, and at the rack the firm magnet 36 attached on d1e. If now the electromagnet 35 is energized, it turns the contact roller under Überwindung of the spring action into the Enlladestellung. Damil the excitation 'umschallende? Electromagnets selbs, ttälig with a certain tension take place, is a elektrostalischer switch (Fig.9) indicate-indicating eight.

That mil the earth connected voucher of the letzlen or the voucher of any other condenser is not with the balls 29 and 32 connected. If now into the Ladestellung¬ the potential rises, then the balls push off each other more and more, until the mobile ball 32 provided with the fork 33 dips into two Queck¬silbernäpfchen and thus the river exciting from the battery 3 supplied and the swivelling electromagnets 35 closes or this current conclusion by means of relays cause lets.

One can regulate the amount of the tension, with which this current conclusion and thus the unloading of the rheostatischen machine take place, mittel~ the adjustable weights 38 and 39. The apparatus is provided to the protection with the glass fall 40. Within the fall also one is with Chlorkalzium gefUIlte bowl 41.

As long as the tension at the balls 29 and 32 remains constant, the outflow, concomitantly the excitation of the magnet continues the accumulators receive the utilizable stream. If the condensers delivered their charge, repulsive Kraft of the balls become smaller, with which the Quecksilberkontakt is interrupted, those. Excitation electromagnets stops and the feather/spring 37 D! e contact roller back into the load position brings, on which the play of neuern can begin. At larger electric charges which can be derived two rheostatische machines can work abaechselnd, so that, while the one will unload, which can be loaded others. It is now easily evident that, if the capacity of the rheostatischen machine is not changed switching will always take place via the electrometer with the same potential of the rheostatischen machine " and the number of plates, thus the transformation relationship the same remains there, then also the current draws dieseIbe tension led from the rheostatischen machine will have.

As long as the tension at the balls 29 and 32 remains constant, the outflow, concomitantly the excitation of the magnet continues the accumulators receive the utilizable stream. If the condensers delivered their charge, repulsive Kraft of the balls become smaller, with which the Quecksilberkontakt is interrupted, those. By the irregularities of the Elektrizitätsquelle the period, in which the siromstösse follows one another, is changed this does not.hat however, as soon as now the tension remains constant, on shop of the accumulators harmful influence. The river led from the rheostatischen machine can be ver¬wendet at times, where it is sufficient constant, directly with evasion of the accumulators. 24 and 25 is the wring leads, to-consumption-places either directly or to storage battery leading.“

14

Execution of the Erhilzung in practice, and it is at all questionable whether the desired result is to be obtained thereby in addition are the large balloons from things with heavy metal nets and - sharpen to and for itself a thing offering no prospects.

In the further the American patent is 1014719 from 16. January 1912 inventors: Walter L. Pennock, Philadelphia, Pennsylvania mentions. The patent claim reads in the translation about follows dermasseri: The patent protection becomes geforden for a collecting tank for electrical charges, which consists of a number of carriers and a metal net, which are held in such a way by these carriers that it is appropriate for particular the carrier mentioned above, which furthermore anchor devices possesses in one level and in approximately even distance, from everyone, which with gemein¬samen points after everyone the carrier mentioned goes out, which furthermore a device, the carriers in their normal position possesses to hold, and in addition a device attached between everyone of the mentioned carriers and the net, which permits each carrier to adapt fast and independently each changes of the air flow.

Also after this patent one lets balloons from silk and such materials, which carry metallic collecting TZE, ascend into air. As is shown by the patent claim, the patent protection sought for the kind of the execution of the balloon herab¬hängenden leader. Because of this small difference of the previous patents I refrain from a more exact explanation.

Would last be that D.R.P. 248580 of the 22.Juni 1912 Inventor: Heinrich Johannsen, Luebeck to state. its patent claim reads as follows: . Procedure for catching Luftelektrizilät by means of senk¬rechter or diagonal leaders, thereby ge marks that into the line a high-tension power source is switched on, for the purpose, the point resistance to lower. “ Patent specification. . Procedure for catching atmospheric electricity by means of more perpendicular or diagonal leaders.

15

Further nothing is well-known over the atmospheric electricity, apart from the fact, .dass in newspapers publications of shining successes of an inventor appear here and there, the one new invention to the Nutzbarmar: hung of atmospheric electricity to have ago made wants and for these purposes money searches.

Tried one, with these people in connection to set, then always turned out that either large sums had to be paid before, in order at all only something details too experienced, or the invention always existed in gleir: hen thoughts: A balloon from silk was suggested, for which a net with many needles should carry. In which way the Anlj! ge before lightning or overvoltage to be g~schützt or like the transformation of the Electricity in a technically useful form as well as their adjustment be made should, of it knew itself the gentlemen neither one seriously thought conception out to make, still for it proofs furnish.

From above-said it follows clearly that the attempts to win atmospheric electricity thereby that air balloons rise as collecting tanks are left, those on a non-metallic envelope of the ballon --herein all inventors agree - a metallic Ergebnie of the preliminary tests

16

Sammel1: 1etz carried, to the goal to lead could not. The balloon had to large loads to carry and received therefore to large extent. Large attack regions, so that surely tearing the whole collecting TZE was to be foreseen had storm, Regenund other atmospheric influences, without talking about the fact to that such large envelopes of the balloon lost dauarnd large quantities gas by diffusion. Thus its use and Rentabllitat were impossible, even if a collection of atmospheric electricity möglfch seems to in this way actually be.

The second error of the past attempts was that all inventors the atmospheric Electricity eusserst directly as statisihen direct current of high tension and Ieiner Stromsterke to use wanted. Nearly insurmountable difficulties of the isolation and adjustment face this application. Procedures, which permit, this kind Electricity into another, less gerährliche form, which was not technically usable commodity, too yerwandeln, yet well-known, which had everything only is found.

All this had to be found only.

Hauptgrllnde of the blherlgen failures

The principal reasons of the past failures can in the following general points to be summarized:

All inventors thought for attaching heavy metallic nets on individual air balloons from nonconductive, tear upable and the gas letting through materials as collecting tanks.

No means had been used, in order to increase the ionization of the collection coefficients of the collector nets by artificial means (radioactive substances, photoelectrically working substances, devices for the education of ultraviolet jets etc.).

No inventor has an attempt with balloon collecting tanks made from sheet metal.

such metallic balloon collecting tanks however rolgende important possess and aur other way not advantages which can be reached: aluminium the metallic coverings is impenetrably for helium and Wasserstoff' them places gJeichzeitig Erosse metallic, weather remainders of Collector surfaces.

Radioactive means etc. can be easily attached inside or outside, whereby the ionization and thus also the collected quantity of the atmospheric electricity is substantially increased.

Such balloon collecting tanks made of light alloy do not need to be large, since they must carry Dur their own small weight and that of the wring lead.

The whole system offers therefore storm and wind w~nig to attack regions and becomes resistant and stable.

One can lift and lower balloon easily by a hoist, So that all repairs, Nachrüllen etc., safely wlhrend the work are auaführbar.

17

4. No inventor recognized importance and meaning of an antenna collecting tank net from several individual collecting tanks, which are connected among themselves by electrical conductor, spread over the earth in air.

5. No inventor recognized the importance of the use such high capacities for these purposes until today as means for the increase of the capacity used with production of atmospheric electricity condenser batteries, whose correct engagement conditions aus¬gearbeitet, as well as at all. (Consequence of the fact is that to today only extremely small electric charges and these in a practically useless type of current were available.)

6. All inventors were always anxious to convert the collected static electricity of air directly into mechanical energy which encountered evenly insurmountable difficulties.

7. So far no devices were used or intended against overvoltages, lightning danger etc. by the inventors. Gleichfalls was possible an adjustment of such an energy in no way. It is impossible to use the atmospheric electricity as long as the obstacles given after 1 to 7 are not eliminated.

The collection of the atmospheric Electricity can with the comparison of the... also on hot summer days, in a boiler, its ifeen iitee: Surface the sunbeams is evenly suspended, the water of the suns to energy-to cooking bring, although the sun mix also large warmth delivers.

If one would concentrate those sunbeams however by large lenses, which must be substantially larger than the boiler surface, on essel, then one could bring the water not only to cooking, but even to evaporation. Without collection of the jets the Wärmedichte is not sufficient on given square a surface for heating.

The same applies in similar sense also to the atmospheric electricity. If one sets up only a Antenna, then only those parts of the atmospheric electricity are tightened, which are in the proximity of the antenna. Since the density and movement speed of the electrically charged particles of the Atmosphere are only small however, then also the induced tension will be in the antenna wire kJein and mit¬hin also the amperage.

The ring or netlike arranged, strongly ionizing collecting systems in accordance with available invention permit however to collect larger electric charges there it electrically charged particles over a surface of 1, 10, to tighten 100 or more qis fortunes. Must rate however here a number of other conditions considered, which are to be described on the basis designs later more near.

The collection of the atmospheric electricity by means of large antenna system has the comparison example mentioned above (collection of the solarly power) opposite the following two advantages, which understood tons use so far nobody recognized and: 1. the application of large collecting surfaces (the individually lenses and/or mirror surfaces, which find during utilization OF solarly heat to application, one can emergency as make large, as the collecting system) 2. the large capacity of the collecting apparatuses for the atmospheric electricity (by the lenses or hollow mirrors one can affect emergency as large of surfaces, as with the antenna system).

If one counts the other difficulties, which the utilization of the solar power in the way, like changes of the seasons, change of the position of the sun to the Zenith, still in addition, then it results that conditions for the collection of atmospheric electricity lie substantially more favorably. The latter is also not to those Application of compact collecting surfaces or at certain locations or such restrictions binds. It supports itself rather by arbitrary ring or netlike arranged wire communication, which are carried for set up strongly ionizing collecting antennas in arbitrary headroom of, ground of in even distances been suitable and these among themselves to connect.

The openings such shape of set up rings or nets know all the the vertical antennas are more largely its, the higher, since the whole line delivers neither warmth nor light shade. The static electricity is continued to store owing to its special characteristics by condenser effect in the antenna wire, and it is possible to distribute it evenly by g~eignete engagements of special condenser batteries for Jn the net and to receive kolossale charge capacities in this way, for which there is no analogy with the collection of the solar power.

For aforementioned reasons it can be counted on the fact that available procedure the production and Nutzb!}rmachung the atmospheric electricity really on a cheap and a comfortable Way will make possible. A lack, which adhered to all past inventions, was that that always one tried to transfer the electricity immediately into mechanical. Even if it e.g. succeeded to design an electrostatic generator from large strength to then would be nevertheless its application because of that

19

Difficulties of the saftey, as well as the isolation of the axles and other parts not possibly. Such uncommonly large tensions would be possible that short-circuit and spark copy could not be avoided. Likewise it is impossible, such large [unknown] to switch off (regate safely and or adjust for even load to feed engines with high-tension rivers foreseen from manifold other obstacles, which forbid at all. After available invention the atmospheric electricity becomes [unknown] of the new [unknown] into mecamsce nergle umgewan et, which differentiated EN aupt palnzips from the past inventions on this areas forms, [unknown], those separate the static electricity by antenna lines in more mospärlscher. Electricity in the form of direct current of very high tension and small amperage [unknown] runs, converted into electro-dynamic oscillation [unknown] energy of high Wechselzahl. Thereby many advantages it is enough and eliminated all disadvantages.

The electro-dynamic oscillation energy formed in closed, oszillatorischen electric circuits produces built machine in another electric circuit, e.g. in one been suitable, by resonance:. effect electromagnetic waves of desired size and mechanical effect. Furthermore the resonance effect of such rivers permits, , in simple and comfortable way a starting, the adjustment and the disconnection of such machines to cause, this takes place simply by means of tendency and/or detuning of the resonance in the transformer circle and the river flowing in the coil of the machine. Such rivers, except for engine enterprise, are further f Urverschiedene other areas derTech.nik directly zuyerwenden, e.g. : Lighting, production of warmth and Elektroche I1ie.

In addition one knows with such rivers a set of Apparatuses without direct firm current inlet, completely apart from the possibility, they feed f Ur wireless telegraphy and telephone to use. In practice large difficulties were to be overcome, because it was not well-known, how one should design such large machines, and how the electromagnetic oscillations necessary for the supply could be adjusted by so high Wechselzahl.

In the following a specification is to be given, how these questions were solved. In Fig. a simple pattern is represented 14 for the transformation of static electricity into dynamic energy of high frequency. For clarity of the design is calibrates an air antenna, but a lnfluenzmaschine accepted. 13 and 14 ssind collection combs .

20

the static electricity the lnfluepzmaschine. 7 and 8 is spark discharge contacts, 6 and 5 switched on condensers, 9 switched on inductive primary coil, 11 and 12 line ends of the secondary winding 10. If the disk of the static electrostatic generator is set by a mechanical Kraft in turn, then comb collects the positive, the A! 1dere the negative electricity.

The allocations of the condensers 5 and 6 are so long loaded, until the screen end becomes so large Spannungserhöhung that the spark gap will pierce 7 to 8. Since over spark gap 7 and 8, over condensers 6 and 5 and inductive resisted themselves 9 a closed electric circuit forms, so entsteheQ, as well-known, into this circles electromagnetic oscillations.

High Wechselzahl

The produced high-swinging rivers in primary circles induce rivers with the same frequency, jedoce of already completely electromagnetic nature in the secondary circle. The electromagnetic oscillations will maintain by new charges of the static electricity. If the number of turns of the primary and Sekundärkreises stands to each other in correct relation, which one can compute with correct application of the resonance coefficients (capacity, inductance and resistance), then one can convert the rivers of the primary circle with high tension in such arbitrarily low tension and higher amperage.

If oscillation unloadings become weaker in primary circles or to diminish completely, begin more wiedrer the charge of the condensers with static electricity, until the spark gap will again pierce. All of this repeats itself so long, when of the static machine electricity is produced by supply of mechanical energy. It is not to be maintained that this application of the static machine and the transformation of the produced electricity do not admit according to above pattern in former times were such remarks were described already often applied and. It is stressed only priority on the fact that in this invention first these.

Experimental assembly for the production of atmospheric electricity for practical purposes brought in application and that the machines (engines), necessary for such rivers, were designed, as well as their circuit and adjustment patterns. By this invention alone the possibility is given to make really atmospheric electricity energy source usable for the technology as practically comfortable 'without by the plant mortal danger for those people exists. It is further only by transforming the static atmospheric electricity been into electromagnetic oscillations possible, the difficulties of the isolation, the building construction, the adjustment, to become starting and switching gentleman off.

From Fig. is evident to 15, how the arrangement for production and transforming of the atmospheric electricity, shown in pattern 14, can be used. Particularly emphasized sei' the main difference between these and other earlier inventions. It consists of it that two parallel spark gaps are an¬gewendet, from which the one as work distance (7) and the other one for the safety device against overvoltages serves.

The latter consists of several individual Funkenstrecken with larger total distance than the work distance, arranged in series connection, and is bridged with very small capacities (aluminium, bl, Cl), which has the purpose to make the even sparking possible in the safeguard distance Continues to mean in Fig. 15 A an air antenna for the collection of atmospheric electricity (specification follows still), 13 connection of the safeguard spark gap with the earth, 5 and 6 condensers, 9 primary coil.

If now by antenna A the positive, atmospheric electricity is anxious with the negative charge of the earth to adjust, then the Luftzwischenraum between the spark gaps prevents itself this reconciliation. How evidently from the design, the resistance of the spark gap is 7 lower than with that! , ndern spark gap, the spark gaps switched from three into series exists and consequently one three times larger air intermediate distance to overcome has. , Thus, as long as the resistance of the spark gap does not become 7 Überlastet, unloadings take place only concerning this.

However if the tension increases by any influences so much that it could become dangerous for the allocation of the condensers 5 and 6 or for the isolation of the windings 9 and 10, then a non-inductive unloading takes place to the earth when correct regulating the resistance of the second spark gap by means of these, without the machine is endangered. ühne this second parallel arranged spark gap also larger resistance than the work spark gap is it possible to collect and make large quantities of electricity usable safely. In Fig. the simplest is selected 1,5 represented pattern and only, in order to explain the basic principle. For practice ~ind more complicated patterns necessarily, from those the most important for usevdifferent intended purposes are prepared and in the following to be described.

Explanation of the principle of the transformation electromagnet punch oscillations into meehanlsche energy

The impact of the closed oscillation circles, consisting of spark gap 1 and two condensers 5 and 6, the primary coil 9, like also the secondary winding 10, is exactly the same, as described 14 for pattern. Are further in Fig. 15 schematically two motor types represented, which serve high Wechselzahl for the transformation of electromagnetic oscillations received from static electricity into mechanical energy.

Tesla Engines

Also on that areas of the high-swinging rivers were to be solved difficult questions. So far only the engine system was Tesla admits (schematically in Fig. to 15 by 16 and 17 represented), on the features of the Hysteresis is based. The engine is compound from iron pins and metallic disks. If on the same electromagnetic oscillations of high Wechselzahl influence, a rotary movement is produced. The description of this pattern serves only for the explanation of the basic principle it does not have however in the execution of large machines any practical interest because of the impossibility of the adjustment and because of the low effectiveness

Resonant Engines

According to available invention all are overcome these difficulties by construction of a machine, which is applicable for elektro¬magnetische energy high change number of more or less absorbed nature. Mg. the first form of a such machine shows 15. The difference between the principle of the Bau'es of these engines opposite the used so far consists of the fact that the engine contains keide magnets and not alone on the principle is based to the magnetic induction (like all current engines and also the Tesla engines), but on combination of the pure static induction with the electromagnetic in the static field. Since the engine is intended for high-swinging rivers, then must be as iron-free as possible er' and manufactured made of well leading metal. It was now shown that for the supply of such engines without magnet metal rivers of more or less absorbed N cannot only be used atur, to switch off but that also due to their special characteristics opposite electromagnetic reesonance features the possibility is given, the engines simply and safely in and and to adjust. These motor types can be called about this resonance engines. In Pig. 15 attached engine consists in his main parts of individual oscillation circles briefly closed in itself. The electromagnetic oscillation poles both the stator (un¬beweglicher part of the engine) and the rotor (mobile part of the engine) are radially embedded or fastened in a suitable firm insulator. Sämlliche of oscillation circles become from the Hauplstromleitung of a eleklromagnetischen source of oscillation suitable frequency and more or less absorbed nature gespelsl. Everyone such oscillatory circuit exists for itself of a closed oscillation circle, given by self induction, Kapazitäl and Ohm's resistance. From it results:

#) a Mögiichkeit to operate also with electromagnetic “oscillations of high Wechselzahl engines of arbitrarily high horse power since a sufficient number of such oscillation circles can be planned parallel in the engine

#) a possibility of designing for the enterprise with eleklromagnetischen oscillations of high Wechselzahl also asynchronously working engines (for similar purposes, for those the current synchronous engines for usual alternating currents or. Three-phase alternating current to be used)

#) a possibility of being able to count not only on a desired number of horse power in advance to obtain but also a widerslandsiähige and a simply executable construction form

#) an ideal Ein and elimination and an adjustment of such Moloren by change of the resonance i.e. by change of the capacity or the

self induction coefficient of the energizing current the more or less good resonance of the individual oscillation circles in relation to the main stream is destroyed or manufactured.

Determined by attempts that the same machine works accordingly differently, ever more or less the mechanical components with their natural oscillations of the natural oscillations of the energizing current to differ. After a set of attempts the engine received in Fig. 15 drawn, simplified execution form. By the wring leads (14 and 15) the engine from the source of the electromagnetic Schwjngungen is fed by high Wechselzahl.

The wring leads are with the secondary transformer 10 over two condensers - A and 6a connected. In certain cases the condenser batteries ä and 6a can be replaced by a parallel switched battery 18 (dots drawn). The stator can be designed in different way. From the stator line (thick Linienzug 11 and I) e.g. twelve branchings go into twelve short circuit oscillation circles, which are radially into the stator surface embedded.

Everyone of these oscillation circles possesses a certain given capacity and self induction, which are so selected that they adapt to the wavelength of the energizing current. These twelve oscillation circles form the twelve electromagnetic fields. Between these twelve oscillation circles, which are connected with the main line, are twelve other oscillation circles, which are been correct on same wavelength, i.e. the same induction coefficients as well as those

same capacity possess, but are connected with the feeder not directly. The oscillation circles connected directly with the feeder are named b and other with A. generally speaking receive the stator twenty-four individual oscillation circles. The first twelve oscillation circles are however not directly metallically connected, 'separate by a cylindrical staff b a surface induction are caused. In order to describe before the saying more near, are in Fig. 16 four such individual oscillation circles and their connections with the main line 14 dargeslellt. Hierflir becomes in this invention a neuarliger condenser benutzl, which is characterized by the fact that it possesses three vouchers. As from Fig. 16 to see is, becomes the short circuit oscillation circle consisting of the two condenser vouchers I and 2, which are short circuit with a metal leader 4 of ineiner turn, by the drilte allocation 3 erregl, which is metallically with the Hauplleilung connected direkl. If the capacity and the Selbstinduktionskoeffizienl are so computed in this drilten line that the own oscillations are in resonance with the oscillations of the main line, then the maximum at electromagnetic energy is supplied to the short circuit oscillation circle...

Wavelength entsprichl.

In practice führl one the KoQdensalorbelege in the form of metallic tubes out (Fig. 17). As the third condenser surface, which is to be considered as exciters, slehl in the Mitle (in Fig. 15 by 3 and b, b, b bezeichnel) a Slab or a tube. Between the individual tubes and also between the exciter electrodes is a guler insulator. Thus one receives a very fesles and comfortable system from oscillation circles for high-swinging rivers both up the stator, and on the rotor discs. These must be made of well isolating material, best from particularly for this worked on art wood and or paper without structure, since usual Holzund paper pulps does not exhibit usually necessary firmness and Isolierrahigkeit.

After the execution described above one receives with good electrical insulating capacity a mechanical firmness, which to all requirements of the art of building of engines correspond, to t. All individual connecting wires 4 (Fig. 16) can also by a strong metallic ring 4 (Fig. 15}, which is fastened on the stator and serves as document for eJnzelne metallic staffs, replace will. Of course must be isolated for special cases of the leaders 4 by isolation disks from the ring. ,

Having such three pole oscillation circles with the same capacity a very high induction to exhibit, then instead of smooth metal cylinders spirals are rolled up in cylinder form, whereby the further execution of the individual induction condenser vouchers has to happen completely exactly according to pattern 16. In the last case one obtains the mechanical firmness thereby that one manufactures the insulating layer from ebonite, fiber or similar material with high firmness and rolls the turns up on such tubes, these however in metallic rings into the stator surface embeds firmly.

In Fig. 17 is the connections of the particulars oscillation circles shown if no third electrode is necessary, and the oscillation circle only for the purpose of the phase shift is used. In the same way two-pole oscillation circles are embedded also in the rotor disc, in the same amount of more ocler also only half as much as in the stator surface. They must possess however the the same capacity and self induction coefficient as the stator oscillation circles.

The individual oscillation circles in the rotor can either. from each other to be isolated, or, as in the description of stator. by a metal ring (4, Fig. 15) to be short circuit with one another. On Fig. 18 and 19 is perspectively represented, like individual S {: hwingungskreise onto the rotor disc to be installed and by rings short circuited. The individual oscillation circles exist (as from Fig. 17 evidently) from two into one another pushed, but from each other isolated metal cylinders (on Fig. 18 with 1 and 2 designation), those, by V erbindungsleitung3 short circuit, an oscillation circle closed in itself form.

The cylinders become with their two ends on the rotor basis (not drawn overview for the sake of) in two rings from IsoliermateriaJ (fiber etc.) with the taps fastens A, A, b, b.

In practice are this-struggle however not necessarily, since the tubes more.der whole length are simply embedded after into the cylindric base of the rotor from IsoIiermaterial, which is fastened a metal cylinder on the rotor axis, on dyrselben axle (isolates or also short circuit) are two metallic rings 6 and 7.

By the special feeder line 4 one half of the oscillation circles is in the same way metallically continued to connect with ring 6, and by the lines 4a the other half with ring 7. In addition, one can connect all ends with a ring or all with both, furthermore even all feeder lines can be switched off, if one regards the axle as a common connecting leader, want one the self induction of the individual oscillation circles to increase, then the rings must be isolated from the axle 6 and 7, and the feeder line 3 is not short circuit as on Fig. the connecting leader 3 can be put to 18, but her between the condenser vouchers I and 2 and the connecting leaders 4 and 4a with the ring 6 and 7 on the rotor axis into some WindungeR (Fig.1 9), here lies.

By Auewahl of suitable capacity and self induction the individual oscillation circles of the rotor must brought to the resonance. become with the energizing current on the stator, this type of rotor resembles very the famous asynchronischen type of the rotors used in three-phase engines, the so-called squirrel wheel. Also the connection of the individual Schwjngungskreise can take place parallel not only with one another, but also in series and Gruppenscha4ung, exactly the same as with usual three-phase engines, only that instead of direct leaders always individual oscillation circles from condenser surfaces and induction resistance are taken.

If now in the two groups of oscillations of A and b oscillation care produced, then one receives generally speaking to Zusammenhange on the stator an electromagnetic rotary field, similar to as one with usual two-phase alternating currents by current shift around 1. Period an electromagnetic rotary field receives. The individual closed primary oscillation circles form here the similar elektroinagnetischen change poles, and the secondary oscillations cause the necessary electromagnetic shifts of these poles. The electromagnetic rotary field is formed here not by electromagnets, but oscillation fields.

Each oscillation circle is to be regarded as an electromagnet fed by alternating current. This electromagnetic rotary field formed on the stator induces electromagnetic oscillations of same kind in on the rotor discs fastened and on same wavelength the tuned oscillation circles. As on the stator an electromagnetic rotary field is formed by cooperation of the individual electromagnetic oscillation circles, then also a same rotary field in the rotor is produced and thus obtains a torque after nearly exactly the same basic laws, as with usual wechseistrom engines.

The resonance engine begins to rotate and can work 1eisten. je' the resonance between the charge stream and the primary and secondary oscillation circles on the stator and on the rotor is better, the more ideally is the effectiveness and the initial torque. The engine can be adjusted by tuning and/or detuning of this resonance both and switched off and easily, by obtaining another Eigenschwingungsperiode and thus another wavelength and frequency by change of the capacity or self induction.

In Fig. the Zuführungsle exists 15! tung II from a simple circle line. In practice however it can be put into some turns to receive to umzwischen two oscillation circles a determining tension. In addition, one can get along with a turn, if one attaches an electromagnetic counterweight for the third electrode in the form of capacities (represented by S or M). Instead of producing by secondary induction in the stator a rotary field, one knows this through-direct induction also in the Schwingungskreise. For the purpose one branches a second ring circuit from the main line before the third electrode off (Fig.) and an adjustable Selbstinduktionsspule (16) in series connection attaches 21 to this branching a capacity or.

The river runs then from the Heuptleitung 15 partly without induction resistance into the ring circuit II and excites without delay a number of Schwin gungskreise (9, 10, 11, 12, 13, 14a, 15a and 16a), about the self induction resistance 16 by the ring circuit I. by the self induction this part around 1/e period is partly retarded (during correct attitude of the resistance) or around 1/e period ahead accelerated (if the phase shift by condensers is caused). Thus however another set of oscillation circles in the stator received (1,2, 3, 4, 5, 6, 7 and 8), of them charge around 1/e period is late or accelerated takes place.

Thus in the stator a rotary field is produced, that the rotor in rotation to bring and. Work to carry out can. The individual oscillation circles are as in Fig. 16 and 17 implemented, only becomes the individual groups of I to 8 (Fig. 21) by ring b and 9 to 16a by a second ring A short circuit, during after Fig. 15 all oscillation circles by a ring to be short circuit. It is possible, on this principle. to build not only asynchronous engines, but also-synchronously working. Then m, uss however the stator line from two main distribution board rings 14 and 15 to couple (Fig.20) exist (without them metallically with one another).

All oscillation circles must receive as with pattern 16 three electrodes.

The rotor can as in Fig. 15 remains oscillation-circles represented.

In Fig. 20 is only stator

In all patterns described so far ...

Alteneck windings to implement, both on the stator and on the rotor.

Then that part of the oscillation circle e.g. on the rotor, which forms side on the rotor disc the capacity, comes (on Fig. designates 17 with I and 2), diametrically more gegen¬über the feeder line which is on the other side of the rotor disc (Fig. 17 with 3 designates), or with multipolar rotors with desired bending. If one half of the rotor disc is suction-wound, then one winds the other half likewise, but in reverse sense, so that between the feeder lines the capacities forming pipes come here, whose feeder lines come the first half between the capacities rolled up first, similarly “, oie with the Haefner Alteneck system the direct current coil are implemented, only with the difference that the individual sections consist here of individual oscillation circles, there however only briefly closed wire coils.

In the same way like the rotor one knows also the stator wickelll. N ur the feeder lines at the end must become the side gebogeIl. Such types permit a special utilization of the Verbindungsleiters of the individual oscillation circles. It continues to be possible after this coil system to switch two or four etc.

Kondensatoren in series by on rotor (or stator) a surface opposite a condenser tube (in Fig.) instead of a connecting leader dieser' 8elege second, for which comes, designates 17 with I and 2 to be appropriate for first same condenser tube. Both condensers becomeal at the ends by lines switched into series with one another.

One has the possibility, in which kind the following new forms of Rotorwicklungen euszuführen:

#) in wreath/ring form, so that all ladder are connected with the axle (parallel system)

#) all condensers are switched to two series and such series again in 2, 3 or 4 and more parallel groups with the axle are connected.

#) all oscillation circles become with one another ge in series, switch etc.

Biography

Hermann Plauson was an Estonian engineer and inventor. Plauson investigated the production of energy and power via atmospheric electricity.

Plauson was the director of the Fischer-Tropsch "Otto Traun Research Laboratories" in Hamburg, Germany during the Weimar Republic of the 1920s. He built on Nikola Tesla's idea for connecting machinery to the "wheelwork of nature". Plauson's US Patent # 1,540,998 describes methods to convert alternating radiant static electricity into rectified continuous current pulses. He developed the Plauson's converter, an electrostatic generator. In 1920, Plauson published a book titled "*Production and Utilization of the Atmospheric Electricity*" (*Gr., Gewinnung und Verwertung der Atmospharischen Elektrizitat*). A copy of this book is in the British Library.

It is believed that he was related to Gertrud Plauson (the exact relationship is unknown; she may be his wife).

Power from the Air (I)

by

Hugo Gernsback

During the war there was developed in Germany a new art --- or science --- that bids fair to revolutionize our present means of obtaining power.

This art, which is as new now as wireless was 25 years ago, will attain proportions during the next 25 years that may appear fantastic today. The inventor of the new science, an engineer of note, Herr Hermann Plauson, has devoted years of labor to his researches and he has now actually in use small power plants, that generate electricity direct from the air, day and night, without interruption at practically no cost, once the plant is constructed.

We had occasion, in one of our former issues, to describe the system, roughly, from cabled dispatches, but complete information is available now. The amount of electrical power that resides in our atmosphere is astounding. Herr Plauson found in his experiments that a single balloon sent aloft to a height of 300 yards gave a constant current at 400 volts of 1.8 amperes, or in 24 hours over 17-1/4 kilowatts! By using two balloons in connection with a special condenser battery, the power obtained was 81-1/2 kilowatts in 24 hours. The actual current delivered was 6.8 amperes at 500 volts.

The best balloons used by the inventor are made of thin aluminum leaf. No fabric was used. A simple internal system of ribs, stays and wires, gives the balloon rigidity as well as a certain amount of elasticity. The balloon, when made airtight, is filled with hydrogen or better, with helium. It will then stay aloft for weeks at a time. The outer surface is dotted with extremely sharp pins, made sharp electrolytically. Ordinary pins did not prove good current collectors, as they lacked extreme sharpness. The pins themselves were made from amalgamated zinc, containing a radium preparation, in order to ionize the air. It was also found that by dotting the outer surface of the balloon with zinc-amalgam more current could be collected. Even better results were obtained with polonium amalgam. Plauson states that the function of these amalgams is purely photoelectric.

One hundred of such captive balloons, separated one hundred yards from each other, will give a steady yield of 200 horsepower. This is the minimum, because in the winter this figure increases up to 400 horsepower, due to the higher electrification of the atmosphere.

We need not go into the technic of how the current is finally made useable for industrial purposes, suffice it to say that the problem has been entirely solved by Herr Plauson. By using batteries of condensers, high tension transformers, etc., the current can be transformed to any form desires. Such as for lighting lamps, running motors, charging storage batteries, etc.

Plauson also invented a sort of electrostatic rotary transformer which gives alternating current without the use of condensers and transformers. Indeed, its output is very great, as it actually ‘sucks’ the current down rapidly from the collector balloons. There is no doubt that this invention will soon come into universal use all over the world. We will see the land dotted with captive balloons, particularly in the country and wherever water power does not abound. Indeed, the time is not distant when nearly all of our power will be derived from the atmosphere. So far it seems to be the cheapest form of power known, it being much cheaper even than water power --- the cheapest form of power known today. Not only that, but as the inventor points out, no devastating thunder storms occur near such aerial power plants, because the balloons act not only as lightning arresters, but they quickly discharge the biggest thunder cloud, safely and noiselessly through their grounded spark gaps.

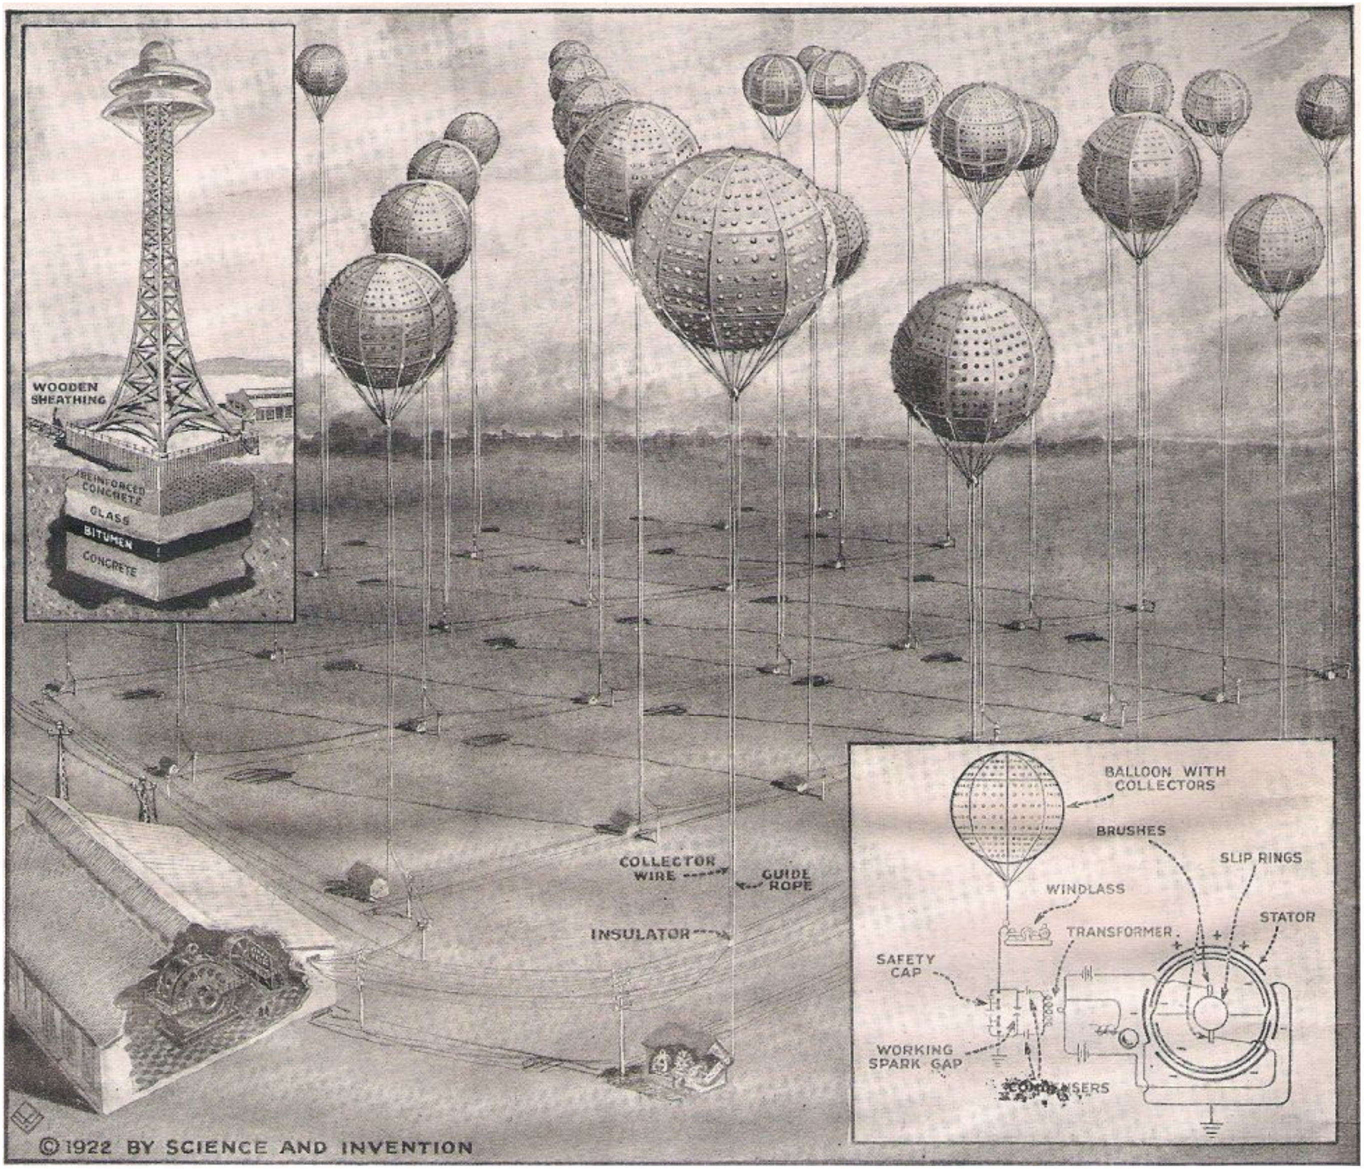
Science & Invention **(March 1922), page 1006, 1007**

Power from the Air (II)

by

Hugo Gernsback

[For many years electrical engineers have endeavored to devise some means whereby it would become possible to utilize the free electrical energy ever present in the atmosphere, but they were not successful, as every now and then an extra heavy surge of static current would rush down the elevated conductor and endanger the lives of the experimenters, or else destroy the apparatus connected with it. A German engineer has, however, devised the somewhat elaborate scheme here shown in brief, and he has succeeded, at least so his report states, in safely extracting several kilowatts of electrical power from the atmosphere with metallic surfaced balloons, elevated to a height of only 1000 feet.]



We have previously treated of the extraction of electrical energy from the atmosphere. The difference of electric potential in different parts of the atmosphere, and the difference between the upper air and earth make it a tempting proposition to obtain power from atmospheric electricity. The power would take the form of high potential difference with a discharge almost of a static nature. It has long appeared rather doubtful to conservative engineers, if such a source of power should really be available. Yet when we see the lightning flash, it certainly suggests very high power, even though the total of its energy may be small, on account of the small duration of the discharge It is not to the thunder storm that we look for getting power from the atmosphere, as the subject is now being seriously investigated. A German scientist, Hermann Plauson, has published a very elaborate work on this subject, and has investigated the use of kites, balloons and towers, for the utilization of the high potentials existing in the air at different altitudes, and has studied out the construction of motors to be operated by the peculiar type of discharge which will be obtained, if the projects are successfully carried out.

We will first speak of the methods used for collecting electricity from the upper air. The author cites several German patents. One of them shows the use of a kite balloon. The balloon is shown floating in the air, kite fashion, and from it hangs a great net or aerial for the collection of electricity. The conductor from the aerial leads to the ground station; quite an elaborate description is given of the net-work which the patentee proposes to have covered with needle points. A windlass takes in or pays out cable for the balloon, and the patentee claims that by sending the apparatus to a height of about one mile he will have 225,000 volts to draw upon. He then speaks o a battery of 20,000 cells in series, which will use up to 40,000 to 50,000 volts in the charging. This certainly provides for a reasonable large fall of potential.

But our author discards this idea and first suggests something more permanent. He proposes the erection of towers to be in the neighborhood of 1,000 feet high, or about the height of the Eiffel Tower. At the summit he has his collecting aerial. The appliance consists of a number of copper tubes; within each one he proposes to burn gas lamps, whose products of combustion will reach the aerial, a collecting net-work covering the tops of the tubes. One of his apprehensions is that if rain should wet his connections trouble might ensue, so he proposes a protection at the top in the shape of a great bell-like shield, resembling in his terms “a Siamese pagoda”. He also compares the form of the protection to that of a great petticoat insulator. Another of his difficulties is that he must have his tower insulated from the earth. He, therefore describes a complicated foundation for his structure. He proposes first to pour in at the bottom of the excavation a foundation of simple concrete. On this he places a layer of asphalt, and then a layer of cast glass, three to ten feet thick, and then comes a reinforced concrete foundation, to which the metallic foot of the tower is to be anchored. This foundation must rise at least seven feet above the ground level, and is to be boarded in on all sides to protect it from moisture. The author’s idea s to erect a number of these towers connected by a horizontal cable, to which the aerials for collection of potentials are secured.

The author strongly advocates balloons as collectors of the electric power of the air. These he depicts covered with spots. These spots indicate areas to be variously coated and prepared to collect potential from the atmosphere.

In the first place he describes the balloon as made of thin metallic leaf supported by internal ribs. Steel wires silver-plated, copper-plated, or aluminum-coated, run from the balloon to the pendant or junction ring. To this ring the tether cable is attached and runs to an insulated windlass on the surface of the earth. The balloon is to rise to an altitude varying from 300 feet to three miles.

The coating of the spots is to be of the thinnest amalgam, of mercury and gold, or zinc, or even polonium, perhaps only 1/2500 inch thick. All over the upper face of the balloon are numberless metal points. To prepare the needle-like wires, they are collected into bundles and are treated electrolytically in a bath, so as to be dissolved in part. This gives a sharp point and roughened surface, all adapted for collecting the electric energy. The points may be of copper, steel, or some hard metallic alloy. After this corrosion. As it may be termed, the wires are plated with gold or other of the so-called noble metals. It is advised that polonium or radium salts be added to the plating bath.

Dr Plauson devotes many pages of his book to describing his motor. This is a rotary motor including a stator and rotor and its peculiarity is that it contains no coils, develops no electromagnetic field properly speaking, but works by static excitation. One typical arrangement is shown in our illustration. The stator plates and rotor plates are concentric with each other, representing segments of cylinders. The alternation of negative and positive charged plates produces the rotation. In the connections there is included a safety spark gap to take care of dangerous potentials. Inductances and capacities are also used and indicated. It was found that the plates heated, owing to the Foucalt currents, and to overcome this, several methods of subdividing the stator and rotor plates, are described by the author.

The whole subject is quite captivating, and it really seems as if the utilization of the electricity of the air may be almost in sight. It would seem possible to carry out experiments in this direction by means of the Eiffel Tower, but of course, the trouble here is that the tower is grounded, and perfect insulation of the collecting surface is absolutely essential.

And now our author gives us some practical details. He says that on the Finland plains he carried out experiments with a balloon made of aluminum leaf with collecting needles of amalgamated zinc with a radium preparation as an ionizer. The surface of the balloon was sprinkled over with zinc amalgam. It was sent up to a height of 300 meters, early 1,000 feet, and was held by a copper-plated steel wire. A constant current of 1.8 amperes at an average of 400 volts potential difference was obtained. This gave nearly three-quarters of a kilowatt, or close to one horsepower. The collector of the balloon insulated from the earth showed a tension of 42,000 volts. By sending up a second balloon with an antenna to the same height at a distance of 100 meters from the first balloon, a current of over 3 amperes was obtained. Then by putting into the circuit a large condenser, whose capacity was equal to the surface capacity of both balloons, and of the antenna connections, the current rose to 6.8 amperes with about 500 volts mean tension. By the use of these two balloons, he eventually ran up the power to 3.4 kilowatts.

elevation of 350 ft., and these students of natural electrical phenomena have found a very desirable location in the Alps, where they can suspend between one mountain and an adjacent one, a strong iron cable having a length of about 2,000 ft. This cable is about 250 feet above the intervening valley, and from it these daring engineers have suspended a coarsely woven wire net, which serves as an electrical capacity to gather the electricity from the atmosphere. As shown in the pictures, the wire net is supplied with numerous sharp points to aid in collecting the current from the air.

As the accompanying photographs of the actual apparatus and wire cable used last year clearly show, an adjustable spark gap of considerable length is provided. By adjusting this spark gap to various lengths, it is possible to judge the voltage of the discharge which leaps the gap at any moment. Mr. F. W. Peek, Jr., the well-known American worker in the realm of high voltage measurements, together with other engineers, have provided tabulated data and curves for various lengths of both needle and sphere type spark gaps. As one of the accompanying diagrams shows, it is a simple matter to calculate the voltage when a certain length of gap is used. The engineer first checks the length of the gap on the chart; he then follows a line horizontally from the gap length, to where it intersects with the angular line on the chart; and from the point of intersection he looks in a visual line downward to a place where the voltage is given. For needle spark gap measurements, the characteristic curve on the chart is practically a straight line, while for sphere gaps the characteristic curve on the voltage versus gap length, is a curved line. Those interested in high voltage measurements by means of the spark gap method can find the voltage-gap tables and charts in the *Standardization Rules* of the American Institute of Electrical Engineers. According to Mr. Peek's researches, the voltage per foot of atmospheric electrical discharges is about 100,000, while in laboratory measurements with A.C., transformer high potential discharges, the average voltage per foot of spark was found to be about 150,000 volts. The voltage of a lightning flash may

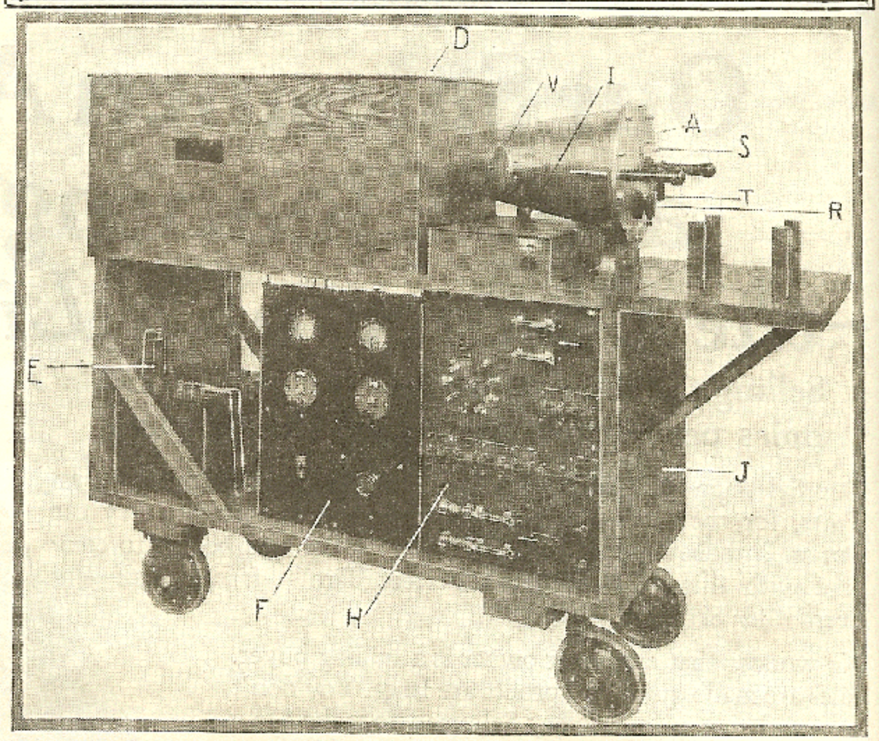
HARNESSING NATURE'S ELECTRICITY

By HENRY TOWNSEND

(*Continued from page* 111)



Remarkable cathode ray oscillograph used by Mr. F. W. Peck, Jr., in causing lightning to write its autograph with a pencil of electrons on a photographic film.

easily be 100,000,000 volts, as Mr. Peek has pointed out in one of his scientific papers.

WHY THE EXPERIMENTS ARE BEING MADE

ONE of the main reasons why these dangerous experiments are being carried on by the three young German scientists, whose names we have already learned, is because science believes that with a sufficiently high voltage, it will be possible for man to disintegrate the atom, and in this way make available a tremendous source of power as yet untapped. These experts have calculated that they will be able to obtain electrical energy in sufficient quantity from one of these powerful atmospheric discharges, to equal the Alpha rays obtained from 220 pounds of radium. As we have mentioned before, these experiments are of course fraught with great danger, and for that reason the experimenters seek refuge in a special lightning-proof hut, which is located about 600 ft., from the spark gap. When electrical storms are in the vicinity, it is especially important that the scientists keep within their protected fortress, for otherwise they would very probably be killed by a stray electrical discharge.

One of the peculiar things about this whole line of experiment is that the average layman does not realize perhaps, that there is a high electrical stress in the atmosphere on clear days, as well as when thunder storms are overhead. This fact has been known for a hundred years and more, and many years ago measurements of the various electrical potentials at increasing altitudes, were observed and measured by scientific investigators. There are a number of different ways in which these high electrical potentials found in the atmosphere can be measured; one of these methods involves the use of a calibrated spark gap. In this case the gap is set to a predetermined length, and when a discharge jumps this gap, the engineers know of course from previous experience and measurements, just what voltage is present. Another method of measuring extra high potentials, such as here encountered, requires the use of a static voltmeter, which involves the use of a stationary and of a movable or rotary set of metal plates, forming a condenser, to which an indicating needle is attached. For voltages above 2,000, static voltmeters have been used in a great many American central stations, and they have many desirable and useful characteristics. Of course as the voltage to be measured increases, the space between the quadrant shaped stationary and movable plates is increased and vice versa. The electrostatic field from voltages below 2,000 is not sufficient to warrant the use of a static voltmeter. Another method of measuring high potentials involves the use of the so-called vacuum tube voltmeter.

The general characteristics of the atmospheric electrical discharges, including lightning, have been measured and recorded by one of the newest scientific instruments, known as the cathode ray oscillograph. By means of this quite remarkable, high voltage scientific apparatus. Mr. Peck, one of the well-known General Electric Company staff of research engineers, has made some very interesting and remarkable discoveries concerning the nature of natural electrical discharges, particularly of lightning discharges. Many people will probably wonder why Mr. Peek and some of his colleagues in the engineering profession, including the three daring German students, Messrs. Brasch, Lange and Urban, play with such dangerous electrical discharges, and why they are at all interested in them. We explained previously why the German savants are intent on finding out all they can about these tremendous voltages obtained from the atmosphere, while Mr. Peck, we may say, also has a very practical reason for carrying on experiments with these death-dealing bolts of Thor. Mr. Peek has been for many years intent on finding out what causes the huge insulators on long distance, high potential transmission lines to break down when electrical storms break loose over these regions.

Atmospheric Electricity Research
[Excerpts]

In the nineteenth and early twentieth centuries, a large number of researchers investigated ways to extract electrical power from the Earth's ambient electric field.

The leader in this field was Dr Hermann Plauson who in the 1920s succeeded in generating significant quantities of electrical power comparable with modern solar photovoltaic systems of a similar scale...

The leader in this field before the Second World War appears to have been Dr Hermann Plauson. Dr Plauson was an Estonian citizen who lived in Hamburg and Switzerland. He carried out experiments in Finland with aerostats manufactured from magnesium-aluminium alloy, covered with electrolytically deposited needles. The needles were further doped with a radium compound to increase local ionisation of the air. (This was the era in which the hands of watches were hand painted with radium to make them luminous in the dark). Zinc amalgam patches were also painted onto the aerostats. Plauson obtained a power output of between 0.72kW and 3.4kW from one and two aerostats 300m above ground level. Dr Plauson filed patents in the USA, Great Britain and Germany in the 1920s. His book "Gewinnung und Verwertung der Atmosphärischen Elektrizität" is the most detailed known account of the technology.

Other atmospheric electricity researchers contemporary to Dr Plauson included Walter Pennock and MW Dewey in the USA, Andor Palencsar in Hungary and Dr Heinrich Rudolph in Germany. Hippolyte Charles Vion in Paris predated them all, putting forward proposals in the 1850s and 1860s.

Heinrich Rudolph made an interesting contribution to the design of the aerostat collectors. In 1898 he designed an elliptical aerostat made up of faceted surfaces to minimise the effect of wind. The design bears a strong resemblance to Northrop's 2003 UCARS unamnned helicopter UAV project. The design uses the Coanda Effect to help keep the aerostat on station and minimise wind effects.

In recent times, the only person who seems to have been active in this field is Dr Oleg Jefimenko. Dr Jefimenko carried out experiments on driving electrostatic motors from the Earth's electric field in the 1970s and has recently called for research into the neglected field of electrostatic motors to be renewed.

MIR's Research Programme

Since 1997 we have been carrying out theoretical research into conversion of atmospheric electricity into useable electrical power.

From a low level (5m high) simple zinc antenna we are able to obtain sufficient charge to light a number of white power LEDs. Further experimental investigations with metallic aerostat collectors and cavity resonant slow wave antennae concepts are ongoing...

Advantages of Atmospheric Electricity

Simple and robust technology
Low Cost technology - much cheaper than photovoltaics or wind turbines

Conversion of Atmospheric Electric Energy

(9 June 1925)

Hermann PLAUSON

Be it known that I, Hermann Plauson, Estonian subject, residing in Hamburg, Germany, have invented certain new and useful improvements in the Conversion of Atmospheric Electric Energy, of which the following is a specification.

Methods of obtaining atmospheric electricity by means of metallic nettings set with spikes which are held by means of ordinary or anchored kite balloons made of fabric and filled with hydrogen, are in theory already known. Atmospheric electricity obtained in this way has been suggested to be used in the form of direct current for the charging of accumulators. This knowledge however is at present only theoretical as the conversion in practice has hitherto been a failure. No means are known of protecting the apparatus from destruction by lightning. The balloons used for collecting the charge must also me be made of very large size in order to be able to support the weight of the metallic netting and the heavy cable connections.

Instead of using heavy metallic netting as collectors attached to single air ballons of non-conducting materials which are liable to be torn and are permeable to the gas, it is proposed to use metallic balloon collectors which have the following important advantages ---

(a) The metallic cases are impenetrable to helium and hydrogen; they also represent large metallic weather-proof collecting surfaces.

(b) Radio active means the like may be easily applied internally or externally; whereby the ionization is considerable increased and therewith also the quantity of atmospheric electricity capable of being collected.

(c) Such balloon collectors of light metal do not require to be of large size as they have to carry only their own moderate weight, and that of the conducting cable or wire.

(d) The entire system therefore offers little surface for the action of storm and wind and is resistant and stable.

(e) Each balloon can be easily raised and lowered by means of a winch so that all repairs, recharging and the like can be carried out without danger during the operation.

It is further proposed to use a collecting aerial network of several separate collectors spread out in the air above the earth, which collectors are interconnected by electrical conductors.

According to this invention charges of atmospheric electricity are not directly converted into mechanical energy, and this forms the main difference from previous inventions, but the static electricity which runs to earth through aerial conductors in the form of direct current of very high voltage and low current strength is converted into electro-dynamic energy in the form of high frequency vibrations. Many advantages are thereby obtained and all disadvantages avoided.

The very high voltage of static electricity of a low current strength can be converted by this invention to voltages more suitable for technical purposes and of greater strength. By the use of closed oscillatory circuits it is possible to obtain electromagnetic waves of various amplitude and thereby to increase the degree of resonance of such current. Such resonance allows various values of inductance to be chosen whereby again the governing of the starting and stopping of machines driven thereby by simply tuning the resonance between coils of the machine and the transformer circuit forming the resonance can easily be obtained. Further, such currents have the property of being directly available for various uses, even without employing them for driving motors, of which there may be particularly mentioned, lighting, production of heat and use in electro-chemistry.

Further, with such currents a series of apparatus may be fed without direct current supply through conductors and also the electro-magnetic high frequency currents may be converted by means of special motors adapted for electro-magnetic oscillations into mechanical energy, or finally converted by special machines into alternating current of low frequency or even into direct current of high potential.

The invention is more particularly described with reference to the accompanying diagrams in which: ---

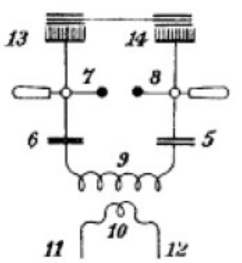

Fig. 2.

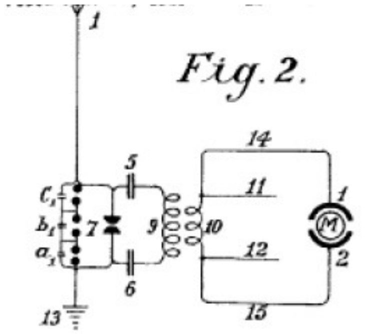

Figure 1 illustrates a simple diagram for converting static electricity into dynamic power of a high number of oscillations. For the sake of clearness in the drawings an influence machine is assumed to be employed and not an aerial antenna. 13 and 14 are combs for collecting the static electricity of the influence machine. 7 and 8 are spark discharging electrodes. 5 and 6 are condensers, 9 an inductive primary coil, 10 secondary coil, 11 and 12 ends of conductors of the secondary coil 10. When the disc of the static influence machine is rotated by mechanical means, the combs collect the electric charges one the positive and the other the negative, and charge the condensers 5 and 6 until such a high potential is formed across the spark gap 7-8, that the spark gap is jumped. As the spark gap 7-8 forms a closed circuit with condensers 5 and 6, and inductive resistance 9, as is well known, waves of high frequency electromagnetic oscillations will pass in this circuit.

The high frequency of the oscillations produced in the primary circuit induces waves of the same periodicity in the secondary circuit. Thus in the primary circuit electromagnetic oscillations are formed by the passage of the spark over the spark gap and these waves are maintained by fresh charges of static electricity.

By suitably selecting the ratio between the number of the coils in the primary and secondary circuits with regard to a correct application of the co-efficients of resonance (especially, inductance and resistance) the high voltage of the primary circuit may be suitably converted into low voltage and high current strength.

When the oscillatory discharges in the primary circuit becomes weaker or entirely cease, the condensers are charged again by the static electricity until the accumulated charge again breaks down the spark gap. All this is repeated as long as electricity is produced by the static machine employing mechanical energy.

An elementary form of the invention is shown in Figure 2 in which two spark gaps in parallel are used one of which may be termed the working gap 7 in Figure 2, whilst the second serves as a safety device for excess voltage and consists of a larger number of spark gaps than the working section, which gaps are arranged in series and are bridged by very small capacities as is illustrated in a, b, c, Figure 2 which allow of uniform sparking in the safety section.

In Figure 2 A is the aerial antenna for collecting charges of atmospheric electricity. 13 is the earth connection of the second part of the spark gap, 5 and 6 are condensers, 9 a primary coil. Now when through the aerial A the positive atmospheric electricity seeks to combine with the negative charge to earth, this is prevented by (the air gap between) the spark gaps. The resistance of the spark gap 7 is, as shown in the drawings, lower than that of the other safety section which consists of three spark gaps connected in series, and consequently a three times greater air resistance is offered by the latter.

So long, therefore, as the resistance of the spark gap 7 is not overloaded, so that the other spark gaps have an equal resistance with it the discharges take place only over spark gap 7. Should however the voltage be increased by and influences so that it might be dangerous for charging the condensers 5 and 6 or for the coil insulation 9 and 10 in consequence of break down, by a correct regulation of this spark gap the second spark gap can discharge free from inductive effects direct to earth without endangering the machine.

Without this second spark gap, arranged in parallel having a higher resistance than the working spark gap it is impossible to collect and render available large quantities of electrical energy.

The actions of this closed oscillation circuit consisting of spark gap 7, two condensers 5 and 6, primary coil 9, and also secondary coil 10 is exactly the same as the one described in Figure 1 with the arrangement of the static induction machine with the only difference that here the second spark gap is provided. The electromagnetic high frequency alternating current obtained can be tapped off from the conductors 11 and 12 for lighting and heating purposes. Special kinds of motors adapted for working with these peculiar electrical charges may be connected at 14 and 15 which can work with static electricity charges or with high frequency oscillations.

In addition to the use of spark gaps in parallel a second measure of security is also necessary for taking off the current. This precaution consists according to this invention, in the introduction of and method of connecting certain protective electromagnets or choking coils in the aerial circuit as shown by S in Figure 3.

A single electromagnet only having a core of the thinnest possible separate laminations is connected with the aerial.

In the case of high voltages in the aerial network or at places where there are frequent thunder storms, several such magnets may however be connected in series.

In the case of large units or plants several electromagnets can be employed in parallel or in series parallel.

The windings of these electromagnets may be simply connected in series with the aerials. In this case the winding preferably consists of several thin parallel wires, which make up together, the necessary section.

The winding may be made of primary and secondary windings in the form of a transformer. The primary windings will be then connected in series with the aerial network, and the secondary winding more or less short-circuited over a regulating resistance or an induction coil. In the latter case it is possible to regulate to a certain extent the effect of the choking coils. In the further description of the connecting and constructional diagrams the aerial electromagnet choke coil is indicated by a simple ring S.

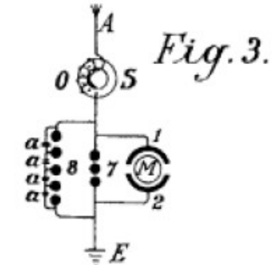

Fig. 3.

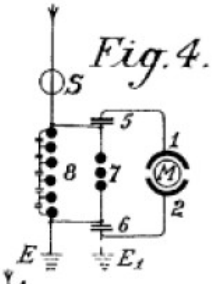

Fig. 4.

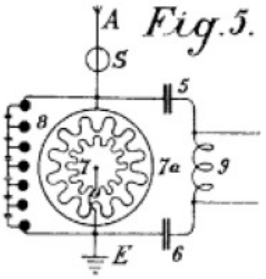

Fig. 5.

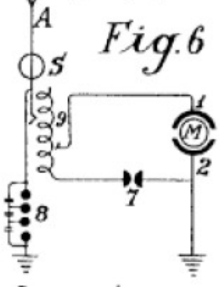

Fig. 6

Figure 3 shows the simplest way of converting atmospheric electricity into electromagnetic wave energy by the use of special motors adapted for high oscillatory currents or static charges of electrical energy. Recent improvements in motors for working with static charges and motors working by resonance, that is to say, having groups of tuned electromagnetic cooperating circuits render this possible but such do not form part of the present invention.

A motor adapted to operate with static charges will for the sake of simplicity be diagrammatically indicated by the two semicircles 1 and 2 and the rotor of the motor by a ring M (Figure 3). A is a vertical aerial or aerial network. S the safety choke or electromagnet with coil O as may be seen is connected with the aerial A. Adjacent the electromagnet S the aerial conductor is divided into three circuits, the circuit 8 giving the safety spark gap, the circuit 7 with the working spark gap, and then a circuit including the stator terminal 1, the rotor and stator terminal 2 at which a connection is made to the earth wire. The two spark gaps are also connected metallically with the earth wire. The method of working these diagrams is as follows:

The positive atmospheric electric charge collected tends to combine with the negative electricity (or earth electricity) connected with the earth wire. It travels along the aerial A through the electromagnet S without begin checked as it flows in the same direction as the direct current. Further, its progress is arrested by two sparks gaps placed in the way and the stator condenser surfaces. The stator condenser surfaces are charged until the charge is greater than the resistance of the spark gap 7, whereupon a spark springs over the spark gap 7 and an oscillatory charge is obtained as by means of the motor M, stator surfaces 1 and 2, and spark gap 7, a closed oscillation circuit is obtained for producing the electromagnetic oscillations. The motor here forms the capacity and the necessary inductance and resistance, which, as is well known, are necessary for converting static electricity into electromagnetic wave energy.

The discharge formed are converted into mechanical energy in special motors and cannot reach the aerial network by reason of the electromagnet or choke. If, however, when a spark springs over the spark gap 7 a greater quantity of atmospheric electricity tends to flow to earth, a counter voltage is induced in the electromagnet, which is greater the more rapidly and strongly the flow of current direct to the earth is. By the formation of this opposing voltage a sufficiently high resistance is offered to the flow of atmospheric electricity direct to earth to prevent a short circuit with the earth.

The circuit containing spark gap 8 having a different wave length which is not in resonance with the natural frequency of the motor, does not endanger the motor and serves as security against excess voltage, which, as practical experiments have shown, may still arise in certain cases, but can be conducted direct to earth through this spark gap.

In the diagram illustrated in Figure 4 the spark gap 7 is shunted across condensers 5 and 6 from the motor M. This construction affords mainly a better insulation of the motor against excess voltage and a uniform excitation through the spark gap 7.

In Figure 5 a diagram is illustrated for transforming large current strengths which may be employed direct without motors, for example, for lighting or heating purposes. The main difference is that here the spark gap consists of as star shaped disk 7 which can rotate on its own axis and is rotated by a motor opposite similarly fitted electrodes 7a. When separate points of stars face one another, discharges take place, thus forming an oscillation circuit over condensers 5 and 6, and inductance 9 for oscillatory discharges. It is evident that a motor may also be directly connected to the ends of the spiral 9.

The construction of the diagram shown in Figure 6 permits of the oscillation circuit of the motor being connected with an induction coil/ Here a regulating inductive resistance is introduced for counter-acting excess voltages in the motor. By cutting the separate coils 9 (coupled inductively to the aerial) in or out the inductive action on the motor may be more or less increased or variable aerial action may be exerted on the oscillation circuit.

Fig. 12.

Fig. 13.

In Figure 7 the oscillation circuit is closed through the earth (E and E1). The spark gap 7 may be prolonged or shortened by more or fewer spark gaps being successively connected by means of a contact arm 7b.

Diagram 8 shows a unipolar connection of the motor with the aerial network. Here two oscillation circuits are closed through the same motor. The first oscillation circuit passes from aerial A through electromagnet S, point *x*, inductance 9a to the earth condenser 6 and further, over spark gap 7 to the aerial condenser 5 and back to *x*. The second oscillation circuit starts from the aerial condenser 5 at the point x^1 over the inductance 9 to the earth condenser 6 at the point x^3 and through the condenser 6 over the spark gap 7 back to x^1. The motor itself is inserted between the two points of the spark gap 7. From this arrangement slightly damped oscillation wave currents are produced.

In the diagram illustrated in Figure 9 a loosely coupled system of connections is illustrated which is assumed to be for small motors for measuring purposes. A indicates the aerial conductor, S the electromagnet in the aerial conductor, 9 the inductance, 7 the spark gap, 5 and 6 condensers, E the earth, M the motor, and 1 and 2 stator connections of the motor. The motor is directly metallically connected with the oscillation circuit.

In Figure 10 a purely inductive coupling is employed for the motor circuit. The motor is connected with the secondary wire 10 as may be seen in Figure 11 in a somewhat modified diagram connection. The same applies to the diagram of Figure 12.

The diagrams hitherto described preferably allow of motors of small and medium strength to be operated. For large aggregates, however, they are too inconvenient as the construction of two or more oscillation circuits for large amounts of energy is difficult; the governing is still more difficult and the danger in switching on or off is greater.

A means of overcoming such difficulties is shown in Figure 13. The oscillation circuit here runs starting from the point x over condenser 5, variable inductance 9, spark gap 7, and the two segments (3a and 4a) forming arms of a Wheatstone bridge, back to x, If the motor is connected by brushes 3 and 4 transversely to the two arms of the bridge as shown in the drawings, electromagnetic oscillations of equal sign are induced in the stator surfaces 1 and 2 and the motor does not revolve. If however the brushes 3 and 4 are moved in common with the conducting wires 1 and 2 which connect the brushes with the stator poles a certain alteration or displacement of the polarity is obtained and the motor commences to revolve.

The maximum action will result if one brush 3 comes on the central sparking contact 7 and the other brush 4 on the part *x*. They are however, usually in practice not brought on the central contact 7 but only held in the path of the bridge segments 4a and 3a in order not to connect the spark gaps with the motor oscillation circuit.

As however, the entire oscillation energy can thereby not act on the motor it is better to carry out the same system according to the diagram 14. The diagram 14 differs from the foregoing only by the motor not being directly metallically connected with the segments of the commutator, but only a primary coil 9 which induces in a secondary coil 10, current which feeds the motor M and takes the place of the rotor. By this arrangement a good transforming action is obtained, a loose coupling and also an oscillation circuit without a spark gap.

In Figure 15 the motor is not purely inductive as in 14, but directly metallically branched off from the primary coil (at x and x^1) after the principle of the auto-transformer.

In Figure 16 instead of an inductance a condenser 6 is in similar manner, and for the same object inserted between the segments 3a and 4a. This has the advantage that the segments 3a and 4a need not be made of solid metal but may consist of spiral coils whereby a more exact regulation is possible and further motors of high inductance may be employed.

The arrangements of Figures 17, 18 and 19 may be employed for use with resonance and particularly with induction condenser motors; between the large stator induction condenser surfaces, small reversing pole condenser surfaces, mall reversing pole condensers are connected, which, as may be seen from Figures 17, 18 and 19 are led together to earth. Such reversing poles have the advantage that with large quantities of electrical energy the spark formation between the separate oscillation circuits ceases.

Figure 19 shows a further method which prevents electromagnetic oscillations of high number of alternations formed in the oscillation circuit striking back to the aerial conductor. It is based on the well known principle that a mercury lamp, one electrode of which is formed of mercury, the other of solid metal such as steel allows an electric charge to pass in only one direction from the mercury to the steel and not vice versa. The mercury electrode of the vacuum tube N is therefore connected with the aerial conductor and the steel electrode with the oscillation circuit. From this it results that charges can pass only from the aerial through the vacuum tube to the oscillation circuit, but not vice versa. Oscillations which are formed on being transformed in the oscillation circuit cannot pass to the aerial conductor.

In practice these vacuum tubes must be connected behind an electromagnet as the latter alone affords no protection against the danger of lightning.

As regards the use of spark gaps, all arrangements as used for wireless telegraphy may be used. Of course the spark gaps in large machines must have a sufficiently large surface. In very large stations they are cooled in liquid carbonic acid or better still in liquid nitrogen or hydrogen; in most cases the cooling may also take place by means of liquefied low homologues of the metal series or by means of hydrocarbons the freezing point of which lies at between –90° C and –40° C. The spark gap casing must also be insulated and be of sufficient strength to be able to resist any pressure which may arise. Any undesirable excess super-pressure which may be formed must be automatically let off. I have employed wit very good results mercury electrodes which were frozen in liquid carbonic acid, the cooling being maintained during the operation from the outside through the walls.

Figure 20 is one of the simplest forms of construction of an aerial network in combination with collectors, transformers and the like illustrated diagrammatically. E is here the earth wire, 8 the safety spark gap, 7 the working spark gap, 1 and 2 the stator surfaces of the motor, 5 a condenser battery, S the protective magnet which is connected with the coil in aerial conductor, A^1 to A^{10} aerial antennae with collecting balloons, N horizontal collecting or connecting wire from which, to the center a number of connections run.

The actual collectors consist of metal sheaths preferably made of an aluminum magnesium alloy, and are filled with hydrogen or helium and are attached t copper plated steel wires. The size of the balloon is selected so that the actual weight of the balloon and the weight of the conducting wire is supported thereby. On top of the balloon aluminum spikes, made and gilded in a special manner hereinafter described, are arranged in order to produce a conductor action. Small quantities of radium preparations, more particularly polonium-ionium or meso-thorium preparations considerably increase the ionization, and therewith the action of these collectors.

In addition to metal balloons, fabric balloons which are superficially metal coated according to Schoop's metal spraying process, may also be employed. A metallic surface may also me produced by lacquering with metallic bronzes, preferably according to Schoop's spraying process or lacquering with metallic bronze powders in two electrical series of widely different metals, because thereby the collecting effect is considerably increased.

Instead of the ordinary round balloons, elongated cigar shaped ones may be employed. In order also to utilize the frictional energy of the wind, patches or strips of non-conducting substances which produce electricity by friction, may be attached to the metalized balloon surfaces. The wind will impart a portion of its energy in the form of frictional electricity, to the balloon casing, and thereby the collecting effect is substantially increased.

In practice however, very high towers (up to 300 meters is fully admissible) may be employed as antennae. In these towers copper tubes rise freely further above the top of the tower. A gas lamp secured against the wind is then lit at the point of the copper tube and a netting is secured to the copper tube over the flame of this lamp to form a collector. The gas is conveyed through the interior of the tube up to the summit. The copper tube must be absolutely protected from moisture at the place at which it enters the tower and also rain must be prevented running down the walls of the tower which might lead to a bad catastrophe. This is done by bell shaped enlargements which expand downwards, being arranged in the tower in the form of high voltage insulators of Siamese pagodas.

Special attention must be devoted to the foundations of such towers. They must be well insulated from the ground, which may be obtained by first embedding a layer of concrete in a box form to a sufficient depth in the ground and inserting in this an asphalt lining and then glass bricks cast about 1 or 2 meters in thickness. Over this in turn there is a ferro-concrete layer in which alone the metal foot of the tube is secured. This concrete block must be at least 2 meters from the ground and be fully protected at the sides by a wooden covering, from moisture. In the lower part of the tower a wood or glass house for the large condenser batteries or for the motors may be constructed. In order to lead the earth connection to the ground water, a well insulated pit constructed of vitreous brick, must be provided. Several such towers are erected at equal distances apart and connected with a horizontal conductor. The horizontal connecting wires may either run directly from tower to tower or be carried on bell shaped insulators similar to those in use for high voltage conductors. The width of the network may be of any suitable size and the connection of the motors can take place at any suitable places.

Fig. 21. Fig. 22.

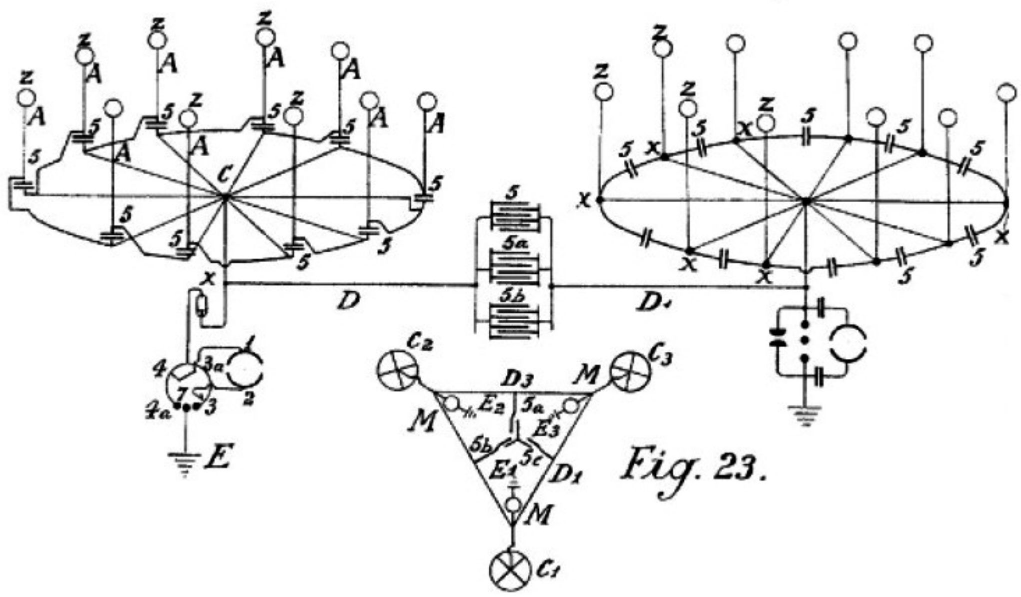

Fig. 23.

In order to collect large quantities of electricity with few aerials it is well to provide the aerial conductor with batteries of condensers as shown in Figures 21 and 22. In Figure 21 the batteries of condensers 5 are connected on the one hand with the aerial electricity collectors Z by the aerial conductor A, and on the other hand interconnected in series with an annular conductor from which horizontal conductors run to the connecting points C to which the earth wire is connected.

Figure 22 shows a similar arrangement, Should two such series of antennae rings be shown by a voltmeter to have a large difference of potential (for example, one in the mountains and one in the plain) or even of different polarity these differences may be compensated for by connecting sufficiently large condenser batteries (5, 5a, 5b) by means of Maji star conductors D and D^1. In Figure 23 a connection of three such rings of collectors to form a triangle with a central condenser battery is illustrated.

The condenser batteries of such large installations must be embedded in liquid gases or in liquids freezing at very low temperatures. In such cases a portion of the atmospheric energy must be employed for liquefying these gases. It is also preferable to employ pressure. By this means the condenser surfaces may be diminished, and still allow for large quantities of energy to be stored, secure against breakdown. For smaller installation the immersing of the condensers in well-insulated oil or the like, suffices. Solid substances on the other hand cannot be employed as insulators.

The arrangement in the diagrams hitherto described was always such that the condenser batteries were connected with both poles directly to the aerial condensers. An improved diagram of the connections for obtaining atmospheric electricity for the condenser batteries has however, been found to be very advantageous. This arrangement consists in that they are connected only by one pole (unipolar) to the collecting network. Such a method of arrangement is very important, as by means of it a constant current and an increase of the normal working pressure or voltage is obtained. If for example a collecting balloon aerial which is allowed to rise to a height of 300 meters, shows 40,000 volts above earth voltage, in practice it has been found that the working voltage (with a withdrawal of the power according to the method hereinbefore described by means of oscillating spark gaps and the like) is only about 400 volts. If however, the capacity of the condenser surfaces be increased, which capacity in the above mentioned case was equal to that of the collecting surface of the balloon aerials, to double the amount, by connecting the condenser batteries with only one pole, the voltage rises under an equal withdrawal of current up to and beyond 500 volts. This can only be ascribed to the favorable action of the connecting method.

In addition to this substantial improvement it has also been found preferable to insert double inductances with electromagnets and to place the capacities preferably between two such electromagnets. It has also been found that the useful action of such condensers can be further increased if an induction coil be connected as inductive resistance to the unconnected pole of the condenser, or still better if the condenser itself be made as an induction condenser. Such a condenser may be compared with a spring which when compressed carries in itself accumulated force, which it again gives off when released. In charging, a charge with reversed sign is formed at the other free condenser pole, and if through the spark gap a short circuit results, the accumulated energy is again given back since now new quantities of energy are induced at the condenser pole connected with the conductor network, which in fact charges with opposite signs to that at the free condenser pole. The new induced charges have of course the same sign as the collector network. The whole voltage energy in the aerial is thereby however increased. In the same space of time larger quantities of energy are accumulated than is the case without such inserted condenser batteries.

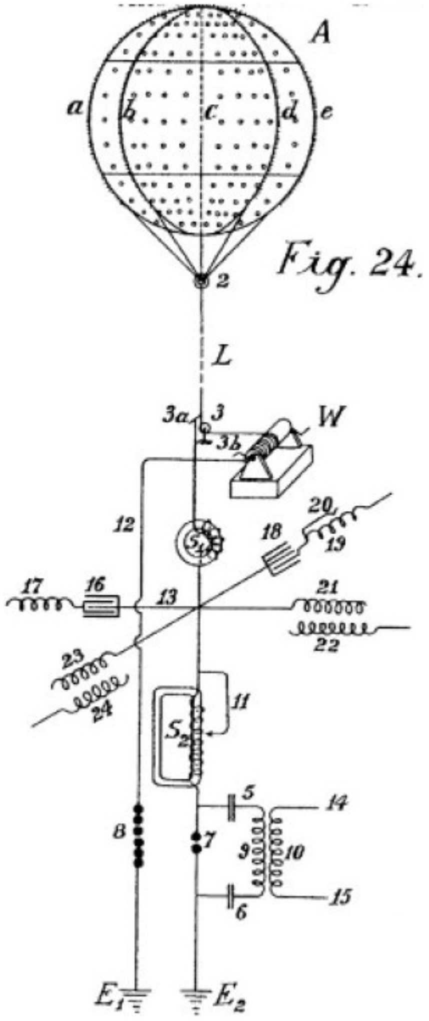

Fig. 24.

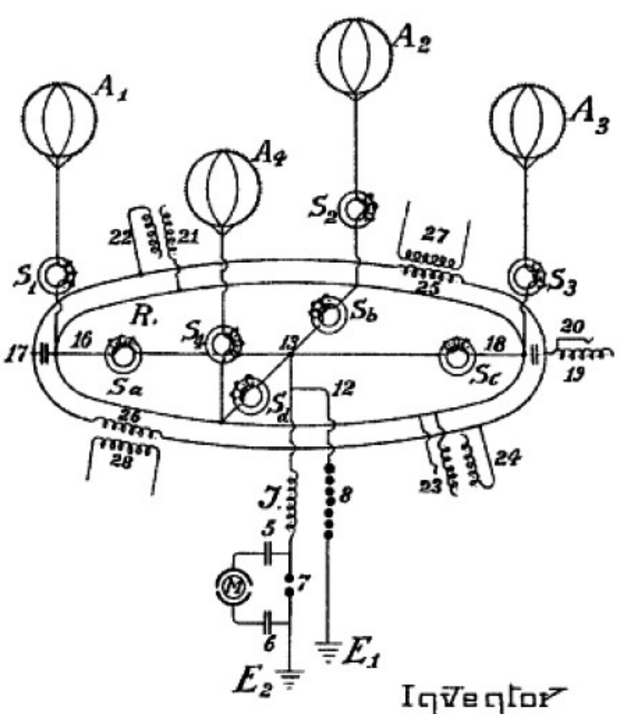
Fig. 25.



In Figures 24 and 25 two different diagrams of connections are more exactly illustrated, Figure 24 shows a collecting balloon and the diagram of the connections to earth. Figure 25 shows four collecting balloons and the parallel connection of the condenser batteries belonging thereto.

A is the collecting balloon made of an aluminum magnesium alloy (electron metal, magnalium) of a specific gravity of 1.8 and a thickness of plate 0.1 to 0.2 mm. Insider there are eight strong vertical ribs of T-shaped section about 10 to 20 mm in height and about 3 mm in thickness with the projecting part directed inwards (indicated by a, b, c, d and so forth); they are riveted together to form a firm skeleton and are stiffened in a horizontal direction by two cross ribs. The ribs are further connected with one another internally and transversely by means of thin steel wires, whereby the balloon obtains great power of resistance and elasticity. Rolled plates of 0.1 to 0.2 mm in thickness made of magnalium alloy are then either soldered or riveted on this skeleton so that a fully metallic casing with smooth external surface is obtained Well silvered or coppered aluminum plated steel wires run from each rib to the fastening ring 2. Further, the coppered steel hawser L preferably twisted out of separate thin wires (shown in dotted lines in Figure 24) and which must be long enough to allow the balloon to rise in the desired height, leads to a metal roller or pulley 3 and from thence to a winch W, well insulated from the earth. By means of this winch, the balloon, which is filled with hydrogen, or helium, can be allowed to rise to a suitable height (300 to 5000 meters) and brought to the ground for recharging or repairs.

The actual current is taken directly through a friction contact from the metal roller 3 or from the wire, or even from the winch or simultaneously from all three by means of brushes (3, 3a and 3b). Beyond the brushes the conductor is divided, the paths being: --- firstly over 12 to the safety spark gap 8, from thence to the earth conductor E^1, and secondly over electromagnet S^1, point 13, to a second loose electromagnet having an adjustable coil S^2, then to the spark gap 7 and to the second earth conductor E^2. The actual working circuit is formed through the spark gap 7, condensers 5 and 6, and through the primary coil 9; here the static electricity formed by oscillatory discharges is accumulated and converted into high frequency electromagnetic oscillations. Between the electromagnets S^1 and S^2 at the crossing point 13, four condenser batteries are introduced which are only indicated diagrammatically in the drawings each by one condenser. Two of these batteries (16 and 18) are made as plate condensers and prolonged by regulating induction coils or spirals 17 and 19 while the two others (21 and 23) are induction condensers. As may be seen from the drawings each of the four condenser batteries 16, 18, 21 and 23 is connected by only one pole to the aerial or to the collector conductor. The second poles 17, 19, 22 and 24 are open. In the case of plate condensers having no inductive resistance an induction coil is inserted. The object of such a spiral or coil is the displacement of phase by the induction current by 1/4 periods, whilst that of the charging current of the condenser poles which lie free in the air, works back to the collector aerial. The consequence of this is that in discharges in the collector aerial the back inductive action of the free poles allows a higher voltage to be maintained in the aerial collecting conductor than would otherwise be the case. It has also been found that such a back action has an extremely favorable effect on the wear of the contacts. Of course the inductive effect may be regulated at will within the limits of the size of the induction coil, the length of the coil in action being adjustable by means of wire connection without induction (see Figure 24, No. 20).

S^1 and S^2 may also be provided with such regulating devices in the case of S^2 (illustrated by 11). If excess voltage be formed it is conducted to earth through the wire 12 and spark gap 8 or through any other suitable apparatus, since this formation would be dangerous for the other apparatus.

The small circles on the collector balloon indicate places at which zinc amalgam or gold amalgam or other photoelectric acting metals in the form of small patches in extremely thin layers (0.01 to 0.05 mm in thickness) are applied to the entire balloon as well as in greater thickness to the conducting network. The capacity of the collector is thereby considerably strengthened at the surface. The greatest possible effect in collecting may be obtained by polonium amalgams and the like. On the surface of the collector balloon metal points or spikes are also fixed along the ribs, which spikes serve particularly for collecting the collector charge. Since it is well known that the resistance of the spikes is less the sharper the spike is, for this purpose it is therefore extremely important to employ as sharp spikes as possible. Experiments made as regards these have shown that the formation of the body of the spike or point also plays a large part, for example, spikes made of bars or rollers with smooth surface, have a many times greater point resistance as collector accumulator spikes than those with rough surfaces. Various kinds of spike bodies have been experimented with for the collector balloons hereinbefore mentions. The best results were given by spikes which were made in the following way. Fine points made of steel, copper, nickel, or copper and nickel alloys, were fastened together in bundles and then placed as anode with the points in a suitable electrolyte (preferably in hydrochloric acid or muriate of iron solutions) and so treated with weak current at 2 to 3 volts pressure. After 2 to 3 hours according to the thickness of the spikes or pins the points become extremely sharp and the bodies of the spikes have a rough surface. The bundle can then be removed and the acid washed off with water. The spikes are then placed as cathode in a batch consisting of solution of gold, platinum, iridium, palladium or wolfram salts or their compounds and coated a the cathode galvanically with a thin layer of precious metal, which must however be sufficiently firm to protect them from atmospheric oxidation.

Such spikes act at a 20-fold lower voltage almost as well as the best and finest points made by mechanical means. Still better results are obtained if polonium or radium salts are added to the galvanic bat when forming he protective layer or coating. Such pins have a low resistance at their points and even at one volt and still lower pressures have an excellent collector action.

In Figure 24 the three unconnected poles are not connected with one another in parallel. That is quite possible in practice without altering the principle of the free pole. It is also preferable to interconnect in parallel to a common collector network, a series of collecting aerials.

Figure 25 shows a diagram for such an installation. A^1, A^2, A^3, A^4 are four metal collector balloons with gold or platinum coated spikes which are electrolytically made in the presence of polonium emanations or radium salts, which spikes or needles are connected over four electromagnets S^1, S^2, S^3, S^4, through an annular conductor R. From this annular conductor four wires run over four further electromagnets Sa, Sb, Sc, Sd, to the connecting point 13. There the conductor is divided, one branch passing over 12 and the safety spark gap 8 to the earth at E^1, the other over inductive resistance J and working spark gap 7 to the earth at E^2. The working circuit, consisting of the condenser 5 and 6 and a resonance motor M, such as hereinbefore described, is connected in proximity round the sparking gap section 7.

Instead of directly connecting the condenser motor of course the primary circuit for high frequency oscillatory current may also be inserted.

The condenser batteries are connected by one pole to the annular conductor R and can be either inductionless (16 and 18) or made as induction condensers as shown by 21 and 23. The free poles of the inductionless condensers are indicated by 17 and 19, those of the induction condensers by 22 and 24. As may be seen from the drawings all these poles 17, 22, 19, 24 may be interconnected in parallel through a second annular conductor without any fear that thereby the principle of the free pole connection will be injured. In addition to the advantages already set forth the parallel connection also allows of an equalization of the working pressure in the entire collector network. Suitable constructed and calculated induction coils 25 and 26 may also be inserted in the annular conductor of the free poles, by means of which a circuit may be formed in the secondary coils 27 and 28 which allows current produced in this annular conductor by fluctuations of the charges of the like appearances to be measured or otherwise utilized.

According to what has been hereinbefore stated separate collector balloons may be connected at equidistant stations distributed over the entire country, either connected directly with one another metallically or by means of intermediate suitably connected condenser batteries through high voltage conductors insulated from earth. The static electricity is converted through a spark gap into dynamic energy of a high number of oscillations and may in such form be coupled as a source of energy b y means of a suitable method f connecting, various precautions being observed and with special regulations. The wires leading from the collector balloons have hitherto been connected through an annular conductor without this endless connection, which can be regarded as an endless induction coil, being able to exert any action on the whole conductor system.

It has now been found that if the network conductor connecting the aerial collector balloons with one another is not made as a simple annular conductor, but preferably short circuited in the form of coils over a condenser battery or spark gap or through thermionic tubes or valves or audions, then the total collecting network exhibits quite new properties. The collection of atmospheric electricity is thereby not only increased but an alternating field may be easily produced in the collector network. Further, the atmospheric electrical forces showing themselves in the higher regions may also be directly obtained by induction. In Figures 26 and 28 a form of construction is shown on the basis of which the further foundations of the method will be more particularly explained.

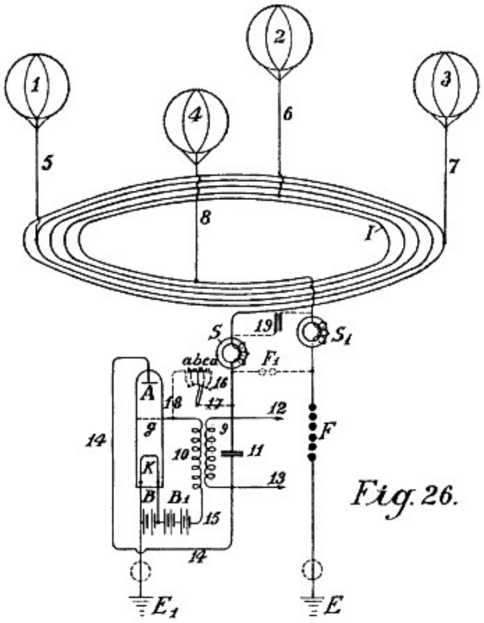


Fig. 26.

In Figure 26, 1, 2, 3, 4 are metal collector balloons, 5, 6, 7, 8 their metallic aerial conductors and I the actual collector network. This consists of five coils and is mounted on high voltage insulators in the air, in high voltage masts (or with a suitable construction of cable embedded in the earth). One coil has a diameter of 1 or 100 km or more. S and S^1 are two protective electromagnets, F the second safety section against excess voltage, E its earth conductor and E1 the earth conductor of the working section. When an absorption of static atmospheric electricity is effected through the four balloon collectors, the current in order to reach the earth connection E1 must flow spirally through the collector network over the electromagnet S, primary induction coil 9, conductor 14, anode A of the audion tube, incandescent cathode K, as the way over the electromagnet and safety spark gap F offers considerably greater resistance. Owing to the fact that the accumulated current flows in one direction, an electromagnetic alternating field is produced in the interior of the collector network coil, whereby the whole free electrons are directed more or less into the interior of the coil. An increased ionization of the atmosphere is thereby produced. In consequence of this the points mounted on the collector balloon show a considerably reduced resistance and therefore increased static charges between the points on the balloon and the surrounding atmosphere are produced. The result of this is a considerably increased collector effect.

A second effect which could not be obtained otherwise is obtained by the electromagnetic alternating field which running parallel to the earth surface, acts more or less with a diminishing or increasing effect on the earth magnetic field, whereby in the case of fluctuations in the current a return induction current of reversed sign is always produced in the collector coil by earth magnetism. Now if, however, a constantly pulsating continuous alternating field is produced as stated in the above collector network I, an alternating current of the same periodicity is produced also in the collecting network coil. As the same alternating field is further transmitted to the aerial balloon, the resistance to its points is thereby considerably reduced, whilst the collector action is considerably increased. A further advantage is that positive electrons which collect on the metal surfaces during the conversion into dynamic current produce a so-called drop of potential of the collector area. As an alternating field is present, the negative ions surrounding the collectors surfaces, when discharge of the collector surfaces takes place produce by the law of induction, an induction of reversed sign on the collector surface and so forth (that is to say again a positive charge). In addition to the advantages hereinbefore set forth, the construction of connecting conductors in coil form when of sufficiently large diameter, allows of a utilization of energy arising in higher regions also in the simplest way. As is well known electric discharges frequently take place at very great elevations which may be observed as St Elmo’s fire or northern lights. These energy quantities have no been available to be utilized up to now. By this invention all these kinds of energy, as they are of an electromagnetic nature and the direction of axis of the collector coils stands at right angles to the earth’s surface, can be more or less absorbed in the same way as a receiver in wireless telegraphy absorbs waves coming from a far distance. With a large diameter of the spiral it is possible to connect large surfaces and thereby to take up also large quantities of energy.

It is well known that large wireless stations in the summer months, and also in the tropics are very frequently unable to receive the signals in consequence of interruptions which are caused by atmospheric electricity, and this takes place with vertical coils of only 40 to 100 meters diameter. If on the contrary horizontal coils of 1 to 100 km diameter be employed very strong currents may be obtained through discharges which are constantly taking place in the atmosphere. Particularly in the tropics or still better in the polar regions where the northern lights are constantly present, large quantities of energy may probably be obtained in this way. A coil with several windings should act the best. In similar manner any alteration of the earth magnetism should act inductively on such a coil.

It is not at all unlikely that earthquakes and spots on the sun will also produce an induction in such collector coils of sufficient size. In similar manner this collector conductor will react on earth current more particularly when they are near the surface of the earth or even embedded in the earth. By combining the previous kind of current collectors so far as they are adapted for the improved system with the improved possibilities of obtaining current the quantities of free natural electricity which are to be obtained in the form of electricity are considerably increased.

In order to produce in the improved collector coil uniform current oscillations of an undamped nature so-called audion high vacuum or thermionic tubes of suitable connection are employed instead of the previously known spark gaps (Figure 26, Nos. 9-18). The main aerial current flows through electromagnet S (which in the case of a high number of alternations is not connected here but in the earth conductor E^1) and may be conveyed over the primary coils in the induction winding through wire 14 to the anode A of the high vacuum grid tube. Parallel with the induction resistance 9 a regulating capacity of suitable size, such as condenser 11 is inserted. In the lower part of the vacuum grid tube is arranged the incandescent filament or the cathode K which is fed through a battery B. From the battery B two branches run, one to the earth conductor E^1 and the other through battery B^1 and secondary coil 10 to the grid above *g* in the vacuum tube. By the method of connections shown in dotted lines, a desired voltage at the grid electrode *g* may also be produced through the wire 17 which is branched off from the main current conductor through switches 16 and some small condensers (*a, b, c, d*) connected in series, and conductor 18, without the battery B^1 being required.

The action of the entire system is somewhat as follows: --

On the connecting conductor of the aerial collector network being short circuited to earth, the condenser pole 11 is charged and slightly damped oscillations are formed in the short circuited existing oscillation circuit formed of the condenser 11 and self inductance 9. In consequence of the coupling through coil 10, fluctuations of voltage take place in the grid circuit 15 with the same frequency, which, fluctuations in turn influence the strength of the electrode current passing through the high vacuum amplifying tube and thus produce current fluctuations of the same frequency in the anode circuit. A permanent supply of energy to the oscillation circuits 9 and 10 consequently takes place, until a condition of balance is set up, in which the consumed oscillation energy is equal to that absorbed. Thereby constant undamped oscillations are now produced in the oscillation circuits 9-11.

For regular working of such oscillation producers high vacuum strengthening tubes are necessary and it is also necessary that the grid and anode voltages shall have a phase difference of 180° so that if the grid is negatively charged, then the anode is positively charged and vice versa. This necessary difference of phase may be obtained by most varied connections, for example, by placing the oscillation circuit in the grid circuit or by separating the oscillation circuit and inductive coupling from the anodes and the grid circuit and so forth.

A second important factor in this way of converting static atmospheric electricity into undamped oscillations is that care must be taken hat the grid and anode voltages have a certain relation to one another; the latter may be obtained by altering the coupling and a suitable selection of the self-induction in the grid circuit, or as shown by dotted lines 16, 17, 18 by means of a larger or smaller number of condensers of suitable size connected in series; in this case the battery B^1 may be omitted. With a suitable selection of the grid potential a glow discharge takes place between the grid *g* and the anode A, and accordingly at the grid there is a cathode drop and a dark space is formed. The size of this cathode drop is influenced by the ions which are emitted in the lower space in consequence of shock ionization of the incandescent cathodes K and pass through the grid in the upper space. On the other hand the number of ions passing through the grid is dependent on the voltage between the grid and the cathode. Thus is the grid voltage undergoes periodic fluctuations (as in the present case) the amount of the cathode drop at the grid fluctuates and consequently the internal resistance of the tube correspondingly fluctuates, so that when a back coupling of the feed circuit with the grid circuit takes place, the necessary means are afforded for producing undamped oscillations and of taking current, according to requirements from the collecting conductor.

The frequency of the undamped oscillations produced is with a suitably loose coupling equal to the self-frequency of the oscillation circuits 9 and 10. By a suitable selection of the self induction of the coil 9 and capacity 11 it is possible to extend from frequencies which produce electromagnetic oscillation of only a few meters wavelength down to the lowest practical alternating current frequency. For large installations a suitable number of frequency-producing tubes of the well-known high vacuum transmission tubes of 0.5 to 2 kw in size may be connected in parallel so that in this respect no difficulty exists.

The use of such tubes for producing undamped oscillations, and also the construction and method of inserting such transmission tubes in an accumulator or dynamo circuit is known and also that such oscillation producing tubes only work well at voltages of 1000 up to 4000 volts, so that on the contrary their use at lower voltages is considerably more difficult. By the use of high voltage static electricity this method of producing undamped oscillations as compared with that through spark gaps must be regarded as an ideal solution particularly for small installations of outputs of from 1 to 100 kw.

By the application of safety spark gaps, with interpolation of electromagnets, not only is short-circuiting avoided but also the taking up of current is regulated. Oscillation producers inserted in the above way form a constantly acting electromagnetic alternating field in the collector coil, whereby as already stated, a considerable accumulating effect takes place. The withdrawal wire or working wire is connected at 12 and 13, but current may be taken by means of a secondary coil which is firmly or movable mounted in any suitable way inside the large collector coil, i.e., in its electromagnetic alternating field, so long as the direction of its axis runs parallel with that of the main current collecting coil.

In producing undamped oscillations of a high frequency (50,000 per second or more) in the oscillation circuits 9 and 11, electromagnets S and S^1 must be inserted if the high frequency oscillations are not to penetrate the collector oil, between the oscillation producers and the collector coil. In all other cases they are connected shortly before the earthing (as in Figures 27 and 28).

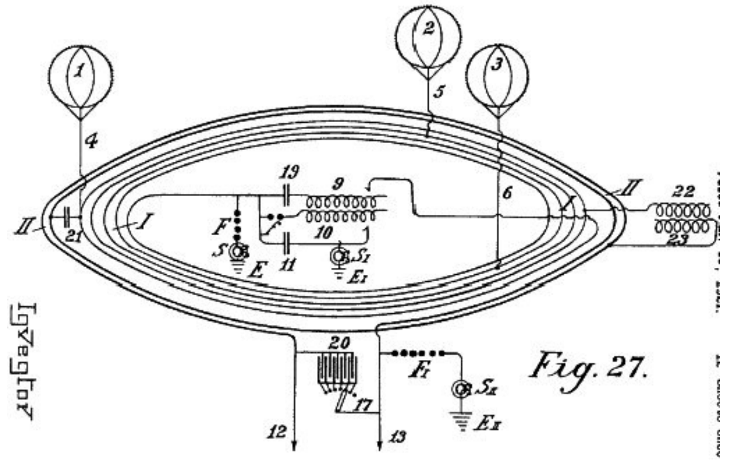

Fig. 27.

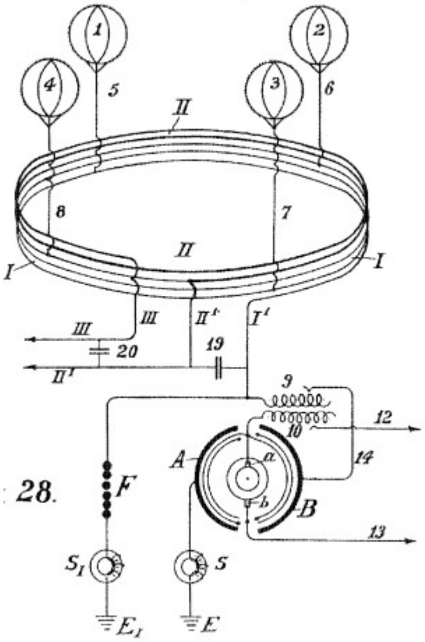
In Figure 27 a second method of construction of the connecting conductor of the balloon aerials is illustrated in the form of a coil. The main difference consists in that in addition to the connecting conductor I another annular conductor II is inserted parallel to the former on the high voltage masts in the air (or embedded as a cable in the earth) but both in te form of a coil. The connecting wire of the balloon aerials is indicated as a primary conductor and also as a current producing network; the other is the consumption network and is not in unipolar connection with the current producing network.

In Figure 27 the current producing network I is shown with three balloon collectors 1, 2, 3 and aerial conductors 4, 5, 6; it is short-circuited through condenser 19 and inductance 9. The oscillation forming circuit consists in this diagram of spark gap f, inductance 10, and condenser 11; the earth wire E, is connected to earth over electromagnet S^1. F s the safety spark gap which is also connected to earth through a second electromagnet S at E. On connecting up the condenser circuit 11 this is charged over the spark gap f whereby an oscillatory discharge is formed. This discharging current acts through inductance 10 on the inductively coupled secondary 9, whereby in the producing network a modification of the potential of the condenser 19 is produced. The consequence of this is that oscillations arise in the coil shaped producer network. These oscillations induce a current in the secondary circuit II, which has a smaller number of windings and a less resistance, the voltage of which, according to the proportion of the number of windings and of the ohmic resistance, is considerably lower whilst the current strength is greater.

In order to convert the current thus obtained into current of an undamped character, and to tune its wavelengths, a sufficiently large regulatable capacity 20 in inserted between the ends 12 and 13 of the secondary conductor II. Here also current may be taken without an earthy conductor, but it is advisable to insert a safety spark gap E1 and to connect this with the earth over an electromagnet S2.

The producer network may be connected with the working network II over an inductionless condenser 21 or over an induction condenser 22, 23. In this case the secondary conductor is unipolarly connected with the energy conductor.



28.

In Figure 28 the connecting conductor between the separate accumulator balloons is carried out according to the autotransformer principle. The collecting coil connects four aerial balloons 1, 2, 3, 4, the windings of which are not made side by side but one above the other. In Figure 28 the collector coil I is shown with a thin line, the metallically connected prolongation coils II with a thick line. Between the ends I^1 and II^1 of the energy network I a regulating capacity 19 is inserted. The wire I^1 is connected with the output wire and with the spark gap F.

As transformer of the atmospheric electricity an arrangement is employed which consists in using rotary pairs of condensers in which the one stator surface B is connected with the main current, whilst the other A is connected with the earth pole. Between these pairs of short-circuited condensers are caused to rotate from which the converted current can be taken by means of two collector rings and brushes, in the form of an alternating current, the frequency of which is dependent on the number of balloons and the revolutions of the rotor. As the alternating current formed in the rotor can act, in this improved method of connection described in this invention, through coils 1 on the inductance 9, an increase or diminution of the feed current in I can be obtained according to the direction of the current by back induction. Current oscillations of uniform rhythm thereby result in the coil shaped windings of the produce network.

As the ends of this conductor are short-circuited through the regulatable condenser 19 these rhythms produce short-circuited undamped oscillations in the energy conductor, the periodicity and wave lengths of which oscillations can be adjusted according to desire by altering the capacity 19 to a given wavelength and therewith also to a given frequency. These currents may also be employed in this form directly as working current through the conductors II^1 and III. By inserting the condenser 20 a connection between these conductors may also be made, whereby harmonic oscillations of desired wavelengths are formed. By this means quite new effects as regards current distribution are obtained. The withdrawal of current can even take place without direct wire connection if, at a suitable point in the interior of the producing network (quite immaterially whether this has a diameter of 1 or 100 km) a coil tuned to these wavelengths and of the desired capacity is firmly or movably mounted in the aerial conductor in such a way that is axial direction is in parallel with that of the collector coil. In this case a current is induced in the producing network, the size of which is dependent on the total capacity and resistance and also on the periodicity employed. A possibility is thereby afforded in future, of taking energy from the producer network by wireless means. As thereby in addition to atmospheric electricity also magnetic earth currents and energy from the higher atmosphere (at leas partially may be simultaneously obtained, this last system for collecting the atmospheric energy is of particular importance for the future.

Of course everywhere instead of spark gaps grid vacuum tubes may be employed as producers for undamped oscillations. The separate coils of the producer network with large diameters may be connected with one another through separate conductors all in parallel or all in series or in groups in series. By regulating the number of oscillations and also the extent of the voltage more or less large collector coils of this kind may be employed. The coils may also be divided spirally over the entire section. The coils may be carried out in angular form or also in triangular, quadrangular, hexagonal or octagonal form.

Of course wires may be carried from a suitable place to the center or also laterally which serve the current waves as guides. This is necessary when the currents have to be conducted over mountains and valley and so forth. In all these cases the current must be converted into a current of suitable periodicity.

As already hereinbefore mentioned separate collecting balloons may be directly metallically interconnected at equidistant stations distributed over the entire country or may be connected by interpolation of suitable condenser batteries by means of high voltage conductors. The static electricity is converted through a spark gap into dynamic energy of a high number of oscillations, and could then in such forms, wit a suitable arrangement of the connections, observing various measures of protection, be employed as source of energy after separate or special regulation.

According to this invention in order to increase the collecting effect of the balloon in the aerial collector conductor or in the earth wire, radiating collectors are employed. These consist either of incandescent metal or oxide electrodes in the form of vacuum grid tubes, or electric arcs (mercury and the like electrodes), Nernst lamps, or finally flames of various kinds may be simply connected with the respective conductor.

It is well known that energy can be drawn of from a cathode consisting of an incandescent body opposite an anode charged with positive electricity (vacuum grid tube). Hitherto however, a cathode was always first directly placed opposite an anode, and secondly the system always consisted of a closed circuit.

Now if we dispense with the ordinary ideas in forming light or flame arcs in which a cathode must always stand directly opposite an anode, charged to a high potential or another body freely floating in the air, or regard the incandescent cathode only as a source of unipolar discharge (which represent group and point discharges in electrostatic machines similar to unipolar discharges), it may be ascertained that incandescent cathodes and less perfectly all incandescent radiators, flames and the like admit of relatively large current densities and allow large quantities of electric energy to radiate into the open space in the form of electron streams as transmitters.

The object of this invention is as described below, if such incandescent oxide electrodes or other incandescent radiators or flames are not freely suspended in space but connected metallically with the earth so that they can be charged with negative terrestrial electricity, these radiators possess the property of absorbing the free positive electrical charges contained in the air space surrounding them (that is to say of collecting them and conducting them to earth). They can therefore serve as collectors and have, in comparison to the action of the spikes, or points, a very large radius of action R; the effective capacity of these collectors is much greater than the geometrical capacity (R_{o-}) calculated in an electrostatic sense.

Now as our earth is surrounded as is well known with an electrostatic field and the difference of potential

$$\frac{\delta V}{\delta h}$$

of the earth field according to the latest investigations, is in summer about 60 to 100 volts and in winter 300 to 500 volts per meter of difference in height (δh), a simple calculation gives the result that when such a radiation collector or flame collector is arranged for example on the ground, and a second one is mounted vertically over it at a distance of 2000 meters and both are connected by a conducting cable, there is a difference in potential in summer of about 2,000,000 volts and in winter even of 6,000,000 volts and more.

According to Stefan Boltzmann's law of radiation, the quantity of energy which an incandescent surface (temperature T) of 1 sq cm radiates in a unit of time into the open air (temperature T_o) is expressed by the following formula:

$S = \delta (T^4 - T^4_o)$ watt./sq cm.

And the universal radiation constant δ is according to the latest researches of Ferry (*Annales de Chimie et de Physique*, 17: 267 [1909]) equal to 6.30 x 10^{-12} watt/sq cm.

Now if an in incandescent surface of 1 sq cm shows, as compared with the surrounding space a periodic fall of potential δV it radiates (independent of the current direction, that is to say of the sign) in accordance with the above formula, for example at a temperature of 3725° C an energy of 1.6 kw/sq cm/second. As for the radiation the same value can be calculated for the collection of energy, but reversed. Now, as carbon electrodes at the temperature of the electric arc support on the current basis a current density up to from 60 to 65 amperes per sq cm no difficulties will result in this direction in employing radiating collectors as accumulators.

If the earth be regarded as a cosmically insulated condenser in the sense of geometrical electrostatics *x* there results from the geometric (compare Edwald Rasch: *Das Elektrische Bogenlicht* [The Electric Arc Light], page 169) capacity of the earth according to Chwolson:

For negative charging 1.3 x 10^6 Coulomb

For negative potential V = 10 x 10^8 volts.

From this there results however, EJT = 24.7 x 10^{24} watt/sec. Now if it is desired to make a theoretic short circuit through an earthed flame collector this would represent an electric total work of about 79,500 x 10^{10} kilowatt years. As the earth must be regarded as a rotating mechanism which thermodynamically, electromagnetically and also kinematically coupled with the sun and star system by cosmic radiations and gravitation a diminution of the electric energy of the earth field is not to be feared. The energies which the incandescent collectors would withdraw from the earth field can only case by the withdrawal of motor work a lowering of the earth temperature (temperature $T_E = 300$) and reduce this to that of the world space (T = O) by using the entire energy. This is however not the case as the earth does not represent a cosmically entirely insulated system. On the contrary there is conveyed to the same according to the recent value corrected by Perry for the solar constants through the radiation from the sun an energy of 18,500 x 10^{10} kw. Accordingly, any lowering of the earth temperature (T_E) without a simultaneous lowering of the sun's temperature (T_s) would contradict Stefan Boltzmann's law of radiation.

$S = \delta (s^4 - T^4)$.

From this it must be concluded that if the earth temperature (T_E) sinks the total radiation S absorbed by the earth increases, and further also that the secular speed of cooling of the earth is directly dependent on that of the sun and the other radiators cosmically coupled with the sun and is connected most closely with these.

The incandescent radiation collectors may, according to this invention, be employed for collecting atmospheric electricity if they (1) are charged with the negative earth electricity (that is to say when they are directly connected by means of a metallic conductor with the earth) and (2) if large capacities (metal surfaces) charged with electricity are mounted opposite them as positive poles in the air. This is regarded as the main feature of the present invention as without these inventive ideas it would not be possible to collect with an incandescent collector, sufficiently large quantities of the electrical charges contained in the atmosphere as the technology requires; the radius of action of the flame collectors would also be too small, especially if it be considered that the very small surface density (energy density) (δ about = 2 x 7 . 10^9 St. E. per sq cm) does not allow of large quantities of charge being absorbed from the atmosphere.

x) Calculated according to Poisson's calculation:

$\Delta V = -4\pi\delta$; as here the alteration of the potential or potential gradients only takes place in the direction o the normal, this calculation assumes the simple form

$$\delta = \frac{1}{4\pi} \times \frac{\delta^2 V}{\delta n^2}$$

It has indeed already been proposed to employ flame collectors for collecting atmospheric electricity and it is known that their collecting effect is substantially greater opposite the points. It is however, not known that the quantities of current which could hitherto be obtained are too small for technical purposes. According to my experiments the reason for this is to be found in the too small capacities of the collector conductor poles. If such flame or radiating collectors have no or only small positive surfaces, their radius of action for large technical purposes is too small. If the incandescent collectors be constantly kept in movement in the air they may collect more according to the speed of the movement, but this again is not capable of being carried out in practice.

By this invention the collector effect is considerably increased by a body charged with a positive potential and of the best possible capacity being also held floating (without direct earth connection) opposite such an incandescent collector which is held floating in the air at a desired height. If for example, a collecting balloon of sheet metal or of metalized balloon fabric be caused to mount to 300 up to 3000 meters in the air and as positive pole it is brought opposite such a radiating collector connected by a conductor to the earth, quite different results are obtained.

The metallic balloon shell (with a large surface) is charged to a high potential by the atmospheric electricity. This potential is greater the higher the collecting balloon is above the incandescent collector. The positive electricity acts concentratedly on the anode floating in the air as it is attracted through the radiation shock ionization, proceeding from the incandescent cathode. The consequence of this is that the radius of action of the incandescent cathode collector is considerably increased and thereby also the collection effect of the collecting balloon surface. Further the large capacity of the anode floating in the air plays therefore an important part because it allows of the taking o large charges, and thereby a more uniform current is obtained even when there is a large consumption: this cannot be the case with small surfaces.

In the present case the metallic collecting balloon is a positive anode floating in the air and the end of the earth conductor of this balloon serves as positive pole surface opposite the surface of the radiating incandescent cathode, which in turn is charged with negative earth electricity being conductively connected to earth.

The process may be carried out by two such contacts (negative incandescent cathode and anode end of a capacity floating in the air) a condenser and an inductive resistance being switched on in parallel, whereby simultaneously undamped oscillations may be formed.

In very large installations it is advisable to connect two such radiating collectors in series. Thus an arc light incandescent cathode may be placed below on the open ground and an incandescent cathode which is heated by special electromagnetic currents be located high in the air. Of course for this the special vacuum Liebig tubes wit or without grids may also be employed. An ordinary arc lamp with oxide electrodes may be introduced on the ground and the positive pole is not directly connected with the collecting balloon, but through the upper incandescent cathode or over a condenser. The method of connecting the incandescent cathode floating in the air may be seen in Figures 29-33.

B is the air balloon, K a Cardan ring (connection with the hawser), C the balloon, L a good connecting cable, P a positive pole, N negative incandescent cathode, and E earth conductor.

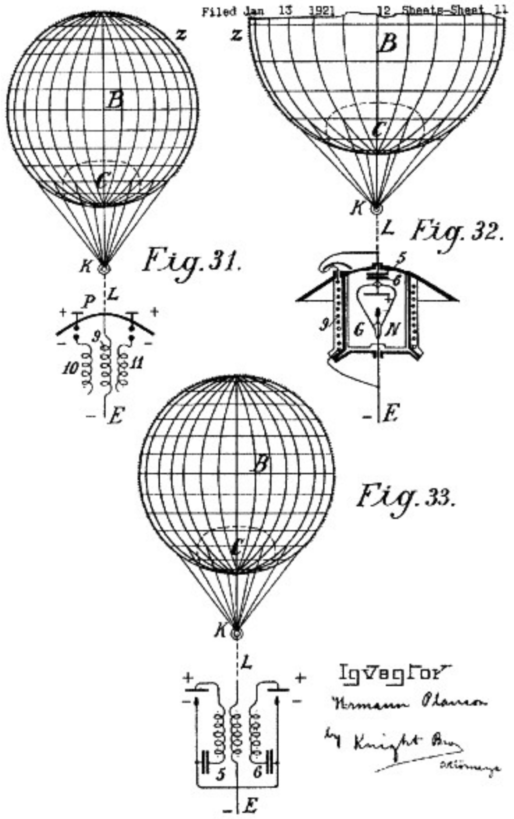
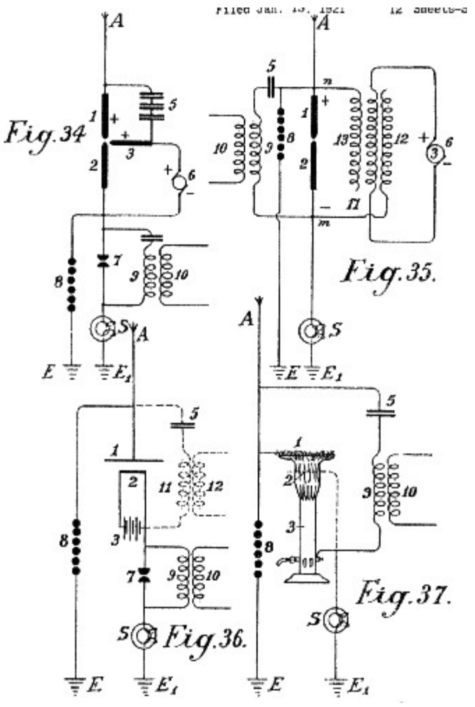
Figure 29 represents the simplest form of construction. If electric oscillations are produced below on the ground by means of a carbon arc lamp or in other suitable way a considerably greater electric resistance is opposed to that in the direct way by inserting an electrical inductive resistance 9. Consequently between P and N, a voltage is formed, and as, over N and P only an inductionless ohmic resistance is present, a spark will spring over so long as the separate induction co-efficients and the like are correctly calculated. The consequence of this is that the oxide electrode (carbon or the like) is rendered incandescent and then shows as incandescent cathode an increased collecting effect. The positive poles must be substantially larger than the negative in order that they may not also become incandescent. As they are further connected with the large balloon area which has a large capacity and is charged at high voltage, an incandescent body which is held floating in the air and a positive pole which can collect large capacities is thereby obtained in the simplest way. The incandescent cathode is first caused to become incandescent by means of separate energy produced on the earth, and then maintained by the energy collected from the atmosphere.

Figure 30 only shows the difference that instead of a round balloon a cigar-shaped one (of metal or metalized fabric) may be employed and also a condenser 5 is inserted between the incandescent cathode and the earth conductor so that a short circuited oscillation circuit over P.N. 5 and 9 is obtained. This has the advantage that quite small quantities of electricity cause the cathode to become incandescent and much larger cathode bodies may be rendered incandescent.



In this form of construction both the incandescent cathode and also the positive electrode may be enclosed in a vacuum chamber as may be seen in Figure 32. A cable L is carried well insulated through the cover of a vessel and ends in a condenser disc 5. The cover is arched in order to keep off the rain. The vessel is entirely or partially made of magnetic metal and well-insulated inside and outside. Opposite the disc 5 another disc 6 and on this again a positive pile of the vacuum tube g with the incandescent cathode (oxide electrode) N is arranged. The negative electrode is on the one hand connected with the earth conductor E, and on the other hand with the inductive resistance 9 which is also connected with the cable L with the positive pole and wound round the vessel in coils. The action is exactly the same as that in Figure 29 only instead of an open incandescent cathode one enclosed in vacuo is employed. As in such collectors only small bodies can be brought to incandescence in large installations a plurality of such vacuum tubes must be inserted in proximity to one another. According to the previous constructions Figures 31 and 33 are quite self evident without further explanations.



Figures 34-37 represent further diagrams of connections over radiating and flame collectors, and in fact, how they are to be arranged on the ground.

Figure 34 shows an arc light collector with oxide electrodes for direct current and its connection; Figure 35 a similar one for alternating current, Figure 36 an incandescent collector with a Nernst lamp and Figure 37 a similar one with a gas flame.

The positive pole 1 of the radiating collectors is always directly connected to the aerial collecting conductor A. In Figure 34 this is further connected over the condenser battery 5 with a second positive electrode 3. The direct current dynamo *b* produces current which flows over between the electrodes 3 and 2 as an arc light. On the formation of an arc the negative incandescent electrode 2 absorbs electricity from the positive poles standing opposite it and highly charged with atmospheric electricity and conveys the same to the working circuit. The spark gap 7, inductive resistance 9 and induction coil 10 are like the ones previously described. The protective electromagnet S guards the installation against earth circuiting, the safety spark gap 8 from excess voltage or overcharging.

In Figure 35 the connection is so far altered that the alternating current dynamo feeds the exciting coil 11 of the induction condenser. 12 is its negative and 13 its positive pole; if the coil 3 on the magnet core of the dynamo is correctly calculated and the periodicity of the alternating current is sufficiently high an arc light can be formed between the two poles 1 and 2. As the cathode 2 is connected with the negatively charged earth, and therefore always acts as a negative pole, a form of rectification of the alternating current produced by the dynamo 3 is obtained, the second half of the period is always suppressed. The working circuit may be carried out in the same way as in Figure 34; the working gap 7 may however be dispensed with, and instead thereof between the points m and n a condenser 5 and an induction resistance 9 may be inserted from which the current is taken inductively.

Figure 36 represents a form of construction similar to Figure 34 only that here instead of an arc lamp a Nernst incandescent body is employed. The Nernst lamp is fed through the battery 3. The working section is connected with the negative pole, the safety spark gap with the + poles. The working spark gap 7 may also be dispensed with and the current for it taken at 12 over the oscillation circuit 5, 11 (shown in dotted lines).

Flame collectors (Figure 37) may also be employed according to this invention. The wire network 1 is connected with the aerial collector conductor A and the burner with the earth. At the upper end of the latter, long points are provided which project into the flame. The positive electrode is connected with the negative over a condenser 5 and the induction coil 9 with the earth.

The novelty in this invention is firstly, the use of incandescent cathodes opposite positive poles which are connected with large metallic capacities as automatic collecting surfaces, (2) the connection of the incandescent cathodes with the earth whereby, in addition to the electricity conveyed to them from the battery or machine which causes the incandescing, also the negative charge of the earth potential is conveyed, and (3) the connection of the positive and negative poles of the radiating collectors over a condenser circuit alone or with the introduction of a suitable inductive resistance, whereby simultaneously an oscillatory oscillation circuit may be obtained. The collecting effect is by these methods quite considerably increased.

I declare that what I claim is: --- [Claims not included here]

British Patent # 157,262

(10 July 1922)

Improvements in Electric Motors

Hermann Plauson // Otto Traun's Forchungs-Laboratorium GmbH

This invention relates to that type of motor in which rotation is produced by means of the attraction and repulsion of surfaces carrying charges of electricity.

According to this invention a stator and rotor are formed of condensor surfaces and charges of electricity thereon imposed in the form of alternating currents of high frequency.

The invention is more particularly described with reference to the accompanying drawing in which: ---

Figure 1 shows a simple form of motor and feed.

The inner plates of the condenser 5 and 6 are charged from a spark gap 7, 8 connected to a source of energy of sufficiently high pressure (alternating or direct current), until the potential has risen so far that a spark springs over.

The spark gap 7, 8 forms with the condenser 5 and self-inductance 9 and condenser 6 a closed oscillatory circuit and alternating currents of high frequency will be produced in this circuit. The high frequency current produced in the primary circuit 9 excite by induction in the secondary circuit 10 currents of the same periodicity.

The improved type of motor is fed by the discharges produced by the induction in the secondary circuit.

Hitherto only Tesla's motor system (shown diagrammatically in Figure 1, 16 and 17) was known for this purpose. The above-mentioned diagram is only shown for illustrating the fundamental principle. It has however no practical interest for carrying out large machines by reason of the impossibility of the regulation and the low efficiency.

Now according to this process, all these defects are overcome by the construction of a machine which is applicable for high frequency currents and of a more or less undamped nature. The difference between the principle of construction of these motors as compared with those hitherto customary consists in that the motor is not based on the principle of magnetic induction only (as have been all motors hitherto and also Tesla's motors).

It has been fund that the machine constructed according to Figure 1 cannot only be fed directly with static electricity but if it is connected to a source of high frequency current it will operate.

The applicants call this new type of motors 'condenser motors' to differentiate them from hitherto existing types.

The simplest form of construction of such condenser motors is shown in Figure 1, and this motor may be fed with high frequency alternating currents.

At a given moment positive electricity is charged by means of the lead 14 to the stator surface 1 and to the brush 3x (Figure 1). The brush 3x is connected with the rotor condenser surface 3, so that both the stator surface 1 and also the rotor surface 3 is charged with positive electricity. The stator surface 1 and the rotor surface 3 being both charged with positive electricity and the second rotor surfaces 4 and 4a by brushes 4x with negative electricity, such motors can then be started by providing intermediate stator surfaces 11, 12, the earth connection 13 of one of which is broken by a switch (not shown) according to the direction of rotation desires, or alternatively the motor may be started by a separate source of alternating current in a manner similar to the starting of synchronous motors of known construction. After a half revolution of the rotor the brush 3x comes in contact with the second collector surface 4 so that now this surface is connected by the brush 3x with the stator surface 1 and the brush 4x with the collector surface 3. Consequently with a reverse direction of current through the second half of the oscillation period all the hereinbefore mentioned effects take place in the reverse direction which, however, produces no alteration in the direction of rotation because the dead points between two directions of oscillation are overcome by inertia.

Although this motor is easy to start it can only be employed for small experimental and measuring purposes because the stator and rotor surfaces are made of solid metal and are heated by Foucalt (eddy) currents. In spite of its simplicity and its unsuitability for use in practice it must however be regarded as a basic type for technical calculations.

The condenser motor shown in Figure 2 differs from Figure 1 by the rotor surfaces consisting of six condenser surfaces connected one behind the other in series and they are connected with three collector surfaces, so that at any one moment only two adjacent collector surfaces come under the two brushes (3 and 4). In its other actions it corresponds to Figure 1. The leads 14 and 15 may be connected either to the ends of the secondary coil 10 or directly with the source of energy. The outer thicker line indicates the stator surfaces 1 and 2 (that is to say the unmoving part of the motor), 11 and 12 shown by thick dotted lines means earthed additional poles of the stator, 8, 9, and 10 are the outer parts of the rotor condenser surfaces which in turn are connected with the collector surfaces 8, 9, and 10. 5, 6, and 7 are the inner parts of the condenser surfaces of the rotor and 3 and 4 are brushes.

Hitherto stator and rotor surfaces of compact metal have been spoken of. These however become highly heated with eddy currents and hardly yield 10-15% of useful effect. In examining into such small useful effects it was found that certain forms of metal sections in the stator and condenser surfaces highly increase these. It was then further found that if slots or notches be cut in the metal surfaces of the stator and rotor in the form of a spiral, not only was a higher useful effect possible, but also an easier starting and even a regulation could be obtained.

Experiments have shown that by such a form of construction it is possible to build a very useful motor for high frequency alternating currents more particularly those of an undamped nature.

If for example the system of construction of a stator shown in Figure 1, but four polar, be taken and the system of rotor construction shown diagrammatically in Figure 5, but with the form of construction of the condensers of the stator as well as of the rotor according to Figure 3, a condenser motor is obtained which works well in either direction for high frequency alternating current. It was also observed that the motors in such forms of construction were found to be more sensitive to resonance effects. Such a motor then works the best if stator and rotor surfaces have equal capacity and self-inductance so that the windings both in the stator and also in the rotor are in resonance.

A motor constructed according to the foregoing kind is already fully technically applicable. But even these motors have a series of faults, more particularly in their building construction. For example, the attachment of the spiral condenser surfaces both of the stator and of the rotor sown in Figure 3 are in practice difficult to carry out. Therefore in practice the condenser and stator surfaces are simply wound of wire or bands in the form shown in Figure 4. Such stator and rotor surfaces may, without further difficulty, be regarded as electromagnetic poles, although they are not made of iron as is the case in electromagnets. Such machines may be spoken of directly as motors for high frequency alternating currents in which the separate pole surfaces consists of wound induction condenser surfaces of which one is sound on the stator and the other on the rotor.

If the coil as shown in Figure 4 be made of well insulated wires the coil can be embedded in insulating material either for the stator or motor surfaces as has already been done in the case of ordinary single and multiphase motors. At the same time the possibility is afforded by increasing the number of turns to produce a greater or smaller alteration of the self induction co-efficients.

In Figure 5 is shown a modified construction of a rotor for a four pole motor consisting of four condenser surfaces 1, 2, 3, 4, of which 1 and 2 are connected though an iductance 9 coupled with the coil 10. Four inner surfaces 5, 6, 7, 8 are provided of which 5 and 6 are directly connected also 7 and 8 similarly connected.

The pairs of like poles are connected by wires 14 and 15 to the source of energy. By a suitable selection of the values of the reactance and capacity in these circuits resonance circuits may be formed.

Having now particularly described and ascertain the nature of our said invention and in what manner the same is to be performed, we declare that what we claim is: --- [Claims not included here]

British Patent # 157,263

Process & Apparatus for Converting Static Atmospheric Electrical Energy into Dynamic Electrical Energy of any Suitable High Periodicity

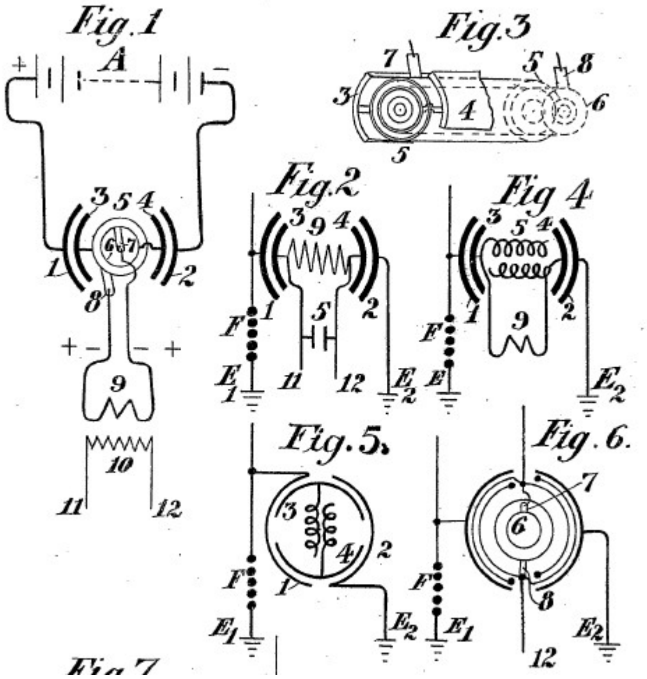
Hermann Plauson // H.O. Traun’s Forschungs-Laboratorium GmbH

Static aerial electricity in the form of direct current can be converted by using spark gaps and with the assistance of oscillatory circuits into dynamic electrical wave energy of a high number of alternations of a more or less undamped nature and in such form --- either direct or by means of a special kind of resonance or 'condenser motors' --- ready to be utilized for technical purposes as mechanical energy.

For small installations this system may be very well employed; about 100 horsepower may be stated as practical limit. In constructions of larger aggregate difficulties as regards the spark gaps however increase considerably. Further it is desirable to convert the accumulated currents of from 100 to 1000 periods which may then be used for the ordinary types of alternating current machines instead of into electromagnetic waves of a high number of alternations.

In experimenting with condenser motors the construction of which forms the object of British Patent # 157,262 it was observed that the rotor, if one pole of the stator surface be connected with the aerials collecting aerial electricity and the other pole with the earth, not only could act as a motor, but if vice versa the rotor connection with the stator be interrupted and the rotor caused to rotate by means of another motor, that when the brushes supply an alternating current the periodicity of which is dependent on the number of poles and the revolutions of the rotor. Such an apparatus may therefore be regarded as a transformer of static into dynamic electrical energy.

The invention is more particularly described with reference to the accompanying diagrams in which: ---



In Figure 1A is a strong accumulator battery, 1 and 2 are the outer poles of the transformer, consisting of simple metallic plates or are as shown in Figures 8-11, made of wire coils without an electromagnet being present. Between these poles an armature is revolubly mounted on a shaft, which armature also consists of two similar cylindrically curved plates 3 and 4. These are metallically connected with two collector rings 5 and 6 on which two brushes 7 and 8 freely run which again are short-circuited with one another over a primary coil 9. 10 is the secondary coil with the free ends 11 and 12. If through the accumulator battery the stator plate 1 is charged with positive electricity, it induces a charge of reverse sign on the rotor surface 3 which is connected by the brushes 7 and 8 over the primary coil 9 with the second rotor surface 4. This latter is therefore charged with positive electricity, which in turn induces negative electricity on the stator surface 2/ Up to this moment everything takes place in the same way as if two condensers were connected one behind the other in the current circuit A. If however, by means of mechanical power, this rotor be caused to rotate, the surface conditions are altered. After a quarter revolution the rotor plates are between the stator plates and therefore no condenser surface faces another. By this means however, the capacity of the entire system is reduced to a minimum and a change of current will also result in the main 9. Now if the rotor be turned further through 90 degrees by mechanical energy the rotor plate 3 comes opposite the stator plate 2 and the rotor plate 4 opposite the stator plate 1, so that then the rotor pates are in a field of reverse sign. A fresh charge of current in the reverse direction now runs through the primary coil 9. After a further half revolution the same action is repeated so that after a full revolution the initial condition is again produced. The result of such a revolution is an alternating current the periodicity of which is equal to the number of revolution. In practice of course not two poles but as many poles as possible would be employed because thereby the number of alternations would e considerably increased. The primary alternating current thus obtained induces in the secondary circuit an alternating current the potential of which is dependent on the winding of the coil. Figure 7 shows a multipolar machine.

If the stator surface 1, instead of being connected with the battery be connected with a collecting aerial network and the other stator surface 2 be directly earthed, but the rotor wich is otherwise constructed as hereinbefore, be rotated by a separate motor a much stronger alternating current results which is to be ascribed to the circumstance that a much higher potential can be charged on the pole surfaces of the stator by reason of the higher pressure of the static electricity than where accumulators are employed. By this means the transformer has of course much larger quantities of energy supplied to it.

Figure 2 shows a mode of connections. The stator surface 1 is connected with the aerial antennae which is connected through the safety spark gap F to earth at E1. The stator surface 2 is directly earthed at E2. The inner revoluble rotor surfaces 3 and 4 are interconnected by means of an induction coil which is constructed directly in the motor. The current is taken as in Figure 1 up to collector rings by means of brushes, which are not shown for the sake of clearness, and further conveyed through the conductors 11 and 12. Between these a condenser 5 may be inserted. There is thereby formed a short oscillatory oscillation circuit free from spark gaps, which circuit consists of the induction coil 9 and condenser 5 and is fed by the periodic charging current impulse. By this means the possibility is afforded of obtaining a kind of current which is characterized by longer periods and is undamped and oscillatory. Of course a simple alternating current may be obtained by cutting out the condenser.

Instead of the induction coil the condenser may also b constructed in the rotor. His can be carried out in such a way that its ends serve directly as collector rings for taking current through the brushes. In Figure 3 such a motor is sketched in perspective, 3 and 4 are the rotor surfaces, 5 and 6 are the condenser surfaces constructed to form part of the rotor consisting of two co-axial cylinders fitting one in the other in such a way that free room is left for the brushes 7 on one end of the condenser cylinder 6.

The condenser may be made in the form of a cylindrically wound spiral forming the capacity and reactance as shown in Figure 4. A further type of transformer is shown in Figure 5. The difference consists in the stator and rotor surfaces not only each assuming a quarter of the circuit but almost the half. By this means the space and the effective condenser surface is better utilized. Charge is produced only when the rotor surfaces face the full scope of the stator surfaces.

In addition a condition is obtained in which the stator surfaces are inductively connected by the rotor surfaces. The consequence of this is that an alternating current simultaneously results which is produced without sparking otherwise the connection is as before.

Figure 6 shows the alternation of the rotor surfaces; the rotor here consists of two cylindrical condenser plates arranged concentrically, each divided into two halves and connected so that half the inner cylinder is connected to half the outer. Such a machine shows the more complete transformer action.

Fig.7.

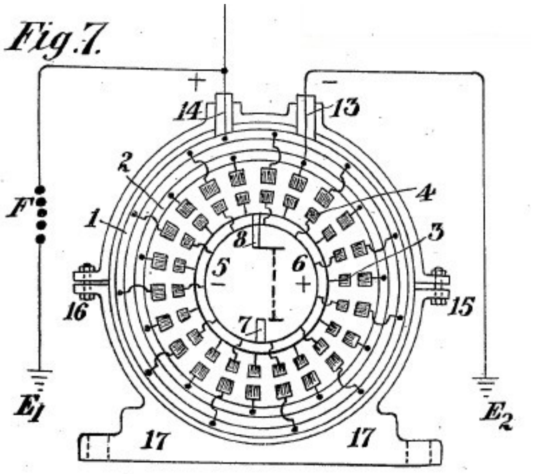


Figure 7 shows a four polar transformer. It consists of a metal casing, the lower half of which is fastened with the foundation plates 17 to the support or foundation. The upper half, the cover, is connected by bolts 15 and 16 firmly with the under part. This upper sleeve or casing is insulated from the under part. Two rings 1 and 2 are cylindrically constructed in the casing. The ring 1 is metallically connected with the collector aerial and the ring 2 with the earth. On both rings an equal number of stator surfaces are mounted side by side but well insulated from one another and thus form an electrostatic field similar to the electromagnetic in many alternating current machines. The rotor consists in similar manner of two rings 5 and 6 on which an equal number of rotor surfaces are fixed so that each stator surface faces a rotor surface. By the brushes 7 and 8 the alternating current formed is removed from the collector. The charge is conveyed by the conductor 14 to and by 13 away. If this rotor be then rotated by means of a motor the positive and negative fields precisely as in the case of magnetizing will alter and thereby an alternating current is formed in the rotor, the periods of which are dependent on the number of the poles and the revolutions per second.

At the commencement it was thought that this apparatus could only be regarded as alternating current converters, but it was soon found that much more energy was necessary to rotate the rotor than might be necessary to overcome the friction. It was then found that the considerable expenditure of energy for rotating the rotor was caused by a conductor being moved through strongly electrostatic fields since the electrostatic lines of force must be cut at right angles and that further in the conductors a stronger current arose than was otherwise to be expected. This apparatus must therefore not only be regarded as a transformer, but also as an energy producer, with the difference that the excitation here is obtained instead of by means of electromagnets, by static fields of high pressure. The entire system may, to some extent, be compared with a dynamo in which the excitation takes place by means of a fixed constant magnet. It was further ascertained that this way of using the atmospheric electricity produced a sort of suction on the collector network, and that thus suitable greater quantities of current could be obtained.

The effects which in this apparatus became evident are extremely interesting and open a prospect of being able to obtain here a great deal more. Merely that these transformer made it possible to transform suitable quantities of atmospheric electricity into alternating current of high or lower frequency (without the use of spark gaps) shows already the extreme utility of these apparatus. Should in future, the construction of larger aggregates be necessary the transformer installation may be constructed in such a way that motors which are fed by a current obtained from an installation with spark gaps produce a certain quantity of energy which may then be employed for producing current according to the last described system.

The results of the examinations made for this may be construed as follows.

(1) If solid electrodes (condenser surfaces, rotor and stator surfaces) are employed they become hot. This effect may be considerably reduced by cutting the electrodes in ribbed form Figure 8, but not entirely removed. This form allows the surface of the condenser plate to be enlarged or increased; the electrodes may be fastened in a simple manner on the under frame by perforation 1, 2, 3, 4, 5.

Fig.8

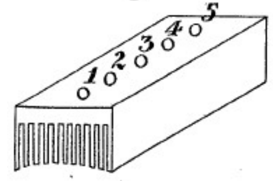

Fig. 9.

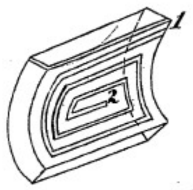

(2) If nicks or notches in spiral form as shown in Figure 9 seen from the side end in Figure 10 in section are employed, not only is the transformer effect greater but the poles yields also more current, but require greater quantities of energy for their movement than a simple commutator action would require.

Fig. 10

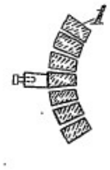

Fig. 11

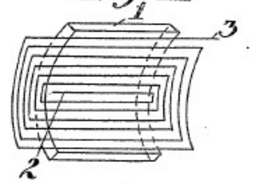

(3) The greatest effect is obtained if the rotor and stator surfaces are wound in flat spiral form of suitably thick wire, and in such a way that the inductive effect combining with the capacity is calculated in suitable proportion and this result is adapted to a suitable periodicity. In practice this is preferably done by the wire bent in spiral form being inserted in a separate vulcanite or hard rubber mass (see Figure 11) so that a smooth pole surface is formed similar to that in phase motors.

Fig.12

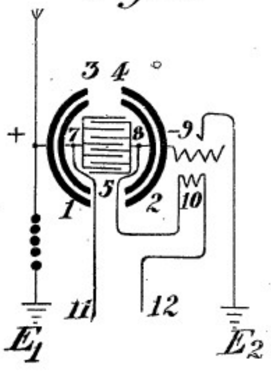

Fig. 13.

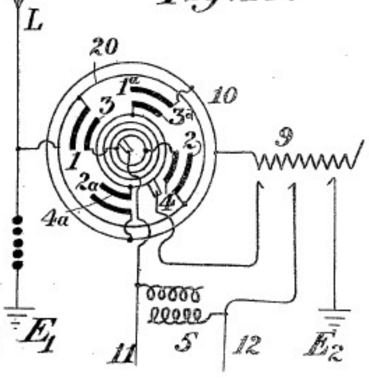

Regular undamped oscillations of a high frequency may however be produced if the converter be carried out in the manner shown in Figure 13. The aerial wire L is metallically connected with the ring 20. To this two pole surfaces 1 and 2 are connected. The inductive earth pole is also connected with a second ring 10 from which again two, poles 1a and 2a are branched off. Of course in similar manner any suitable number of poles may be branched of. In similar manner there are in the rotor two poles fastened to one another (3 and 4 and 3a and 4a) connected with separate collector rings. From these two rings the current is collected by means of two brushes. The induced alternating current is however directly metallically connected with an inductive earth stator conductor over an induction coil 9. Further a combined inductance and capacity 5 is inserted between the two wires 11 and 12 in parallel with the converter. By this means a sparkless oscillatory circuit is obtained which can act on the exciting current in the stator. This produces however, a periodic alteration of the charging quantities according to the oscillation curves of the rotor currents in consequence of which the stator charge also commences with resonance oscillations and if the stator and rotor surfaces are calculated to one another in such a way that they are adapted to form oscillations of waves of similar length the entire converter is caused to oscillate and furnishes undamped oscillations of a high number of alternations, but of periodically changed amplitude, the form of which is dependent on the amplitude of the main alternating current and is caused by the number of the poles and revolutions per second. Thus an alternating current of, for example, 100 periods is formed, the separate periods of which are formed by undamped oscillations of a higher number of alternations. In Figures 14-16 four other diagrams of converters are illustrated, the object of which is not to produce usual alternating current, but oscillations of high frequency.

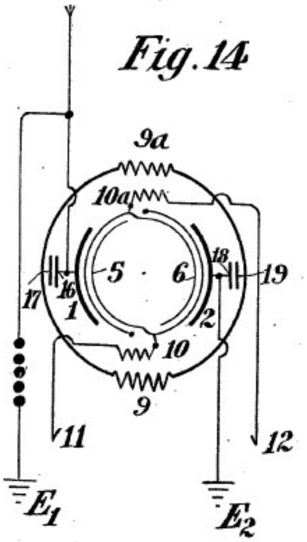

Fig. 14

The main difference of these systems from those previously described is that from the connection of the collecting aerials is made between the stator pole 1 (Figure 14) and one pole 16 of the condenser 17 and the earth connection between a second stator pole 2 and the pole 18 of the condenser 19. The other poles of these condensers 17 and 19 are short circuited through a ring over two inductive primary coils 9 and 9a with one another. The secondary coils form the rotor conductors 10 and 10a. The rotor itself is constructed in the manner shown in Figure 6 of two short-circuited plate condensers which may be wound as shown in Figure 11. In similar manner of course the stator surfaces may also be formed. The collector rings of the rotor with the two brushes for collecting current are here not shown in order to simplify the drawings. By the connection of the two condensers in the exiting circuit of the converter and also by the action of the alternating current produced in the rotor on the stator circuit, with a correct calculation of the capacity and the self-induction co-efficients a maximum action may be obtained. The kind of current produced will be similar to that described for Figure 12.

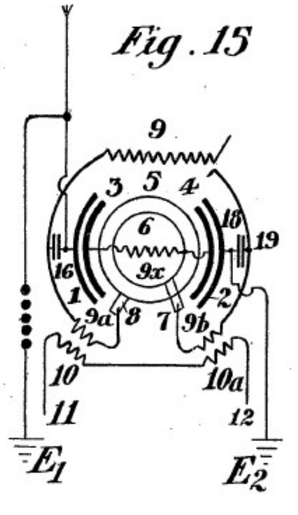

Fig. 15

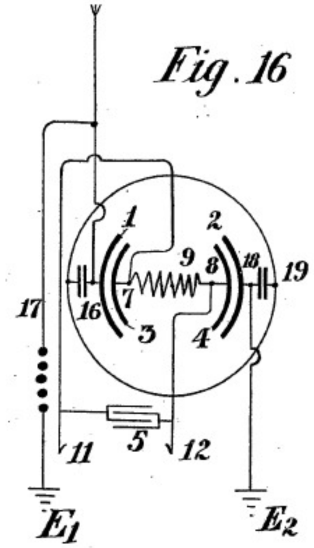
The novelty of the converter illustrated in Figure 15 consists mainly in that the current resulting in the rotor is not directly employed, but only serves a exciter of the primary coils 9a and 9b. The working current is produced in the secondary coils 10 and 10a and further conducted through the conductors 11 and 12. The stator current may be brought by the regulatable inductive resistance 9 to the same resonance as the rotor current.

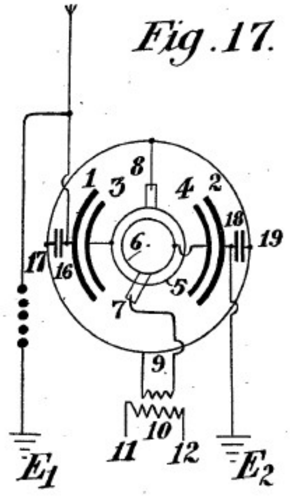
Fig. 16



In Figure 16 a very similar system is shown to Figure 14. The condenser 5 is however connected in parallel with the converter; and by the inductive resistance constructed in the rotor a short circuited oscillatory circuit is formed which gives extraordinarily good results and is simple in construction.

The inductive resistance 9 may also instead of being constructed in the rotor be constructed as primary coil employed outside the rotor and short circuit the oscillatory circuit over the stator surfaces (see Figure 17).

Fig. 17.



The last six types serve only for producing oscillations of a high number of alternations. If it be desired to obtain ordinary alternating current there complicated constructional arrangements are not required as the types illustrated in Figures 1 to 11 suffice. It is self-evident that these arrangements may be altered in various ways by means of different condenser surfaces in practice.

Having now particularly described and ascertained the nature of our said invention and in what manner the same is to be performed, we declare that what we claim is: --- [Claims not included here]

Biography

Hermann Plauson was an Estonian engineer and inventor. Plauson investigated the production of energy and power via atmospheric electricity.

Plauson was the director of the Fischer-Tropsch "Otto Traun Research Laboratories" in Hamburg, Germany during the Weimar Republic of the 1920s. He built on Nikola Tesla's idea for connecting machinery to the "wheelwork of nature". Plauson's US Patent # 1,540,998 describes methods to convert alternating radiant static electricity into rectified continuous current pulses. He developed the Plauson's converter, an electrostatic generator. In 1920, Plauson published a book titled "*Production and Utilization of the Atmospheric Electricity*" (*Gr., Gewinnung und Verwertung der Atmospharischen Elektrizitat*). A copy of this book is in the British Library.

It is believed that he was related to Gertrud Plauson (the exact relationship is unknown; she may be his wife).

Power from the Air (I)

by

Hugo Gernsback

During the war there was developed in Germany a new art --- or science --- that bids fair to revolutionize our present means of obtaining power.

This art, which is as new now as wireless was 25 years ago, will attain proportions during the next 25 years that may appear fantastic today. The inventor of the new science, an engineer of note, Herr Hermann Plauson, has devoted years of labor to his researches and he has now actually in use small power plants, that generate electricity direct from the air, day and night, without interruption at practically no cost, once the plant is constructed.
We had occasion, in one of our former issues, to describe the system, roughly, from cabled dispatches, but complete information is

available now. The amount of electrical power that resides in our atmosphere is astounding. Herr Plauson found in his experiments that a single balloon sent aloft to a height of 300 yards gave a constant current at 400 volts of 1.8 amperes, or in 24 hours over 17-1/4 kilowatts! By using two balloons in connection with a special condenser battery, the power obtained was 81-1/2 kilowatts in 24 hours. The actual current delivered was 6.8 amperes at 500 volts.

The best balloons used by the inventor are made of thin aluminum leaf. No fabric was used. A simple internal system of ribs, stays and wires, gives the balloon rigidity as well as a certain amount of elasticity. The balloon, when made airtight, is filled with hydrogen or better, with helium. It will then stay aloft for weeks at a time. The outer surface is dotted with extremely sharp pins, made sharp electrolytically. Ordinary pins did not prove good current collectors, as they lacked extreme sharpness. The pins themselves were made from amalgamated zinc, containing a radium preparation, in order to ionize the air. It was also found that by dotting the outer surface of the balloon with zinc-amalgam more current could be collected. Even better results were obtained with polonium amalgam. Plauson states that the function of these amalgams is purely photoelectric.

One hundred of such captive balloons, separated one hundred yards from each other, will give a steady yield of 200 horsepower. This is the minimum, because in the winter this figure increases up to 400 horsepower, due to the higher electrification of the atmosphere.

We need not go into the technic of how the current is finally made useable for industrial purposes, suffice it to say that the problem has been entirely solved by Herr Plauson. By using batteries of condensers, high tension transformers, etc., the current can be transformed to any form desires. Such as for lighting lamps, running motors, charging storage batteries, etc.

Plauson also invented a sort of electrostatic rotary transformer which gives alternating current without the use of condensers and transformers. Indeed, its output is very great, as it actually ‘sucks’ the current down rapidly from the collector balloons. There is no doubt that this invention will soon come into universal use all over the world. We will see the land dotted with captive balloons, particularly in the country and wherever water power does not abound. Indeed, the time is not distant when nearly all of our power will be derived from the atmosphere. So far it seems to be the cheapest form of power known, it being much cheaper even than water power --- the cheapest form of power known today. Not only that, but as the inventor points out, no devastating thunder storms occur near such aerial power plants, because the balloons act not only as lightning arresters, but they quickly discharge the biggest thunder cloud, safely and noiselessly through their grounded spark gaps.

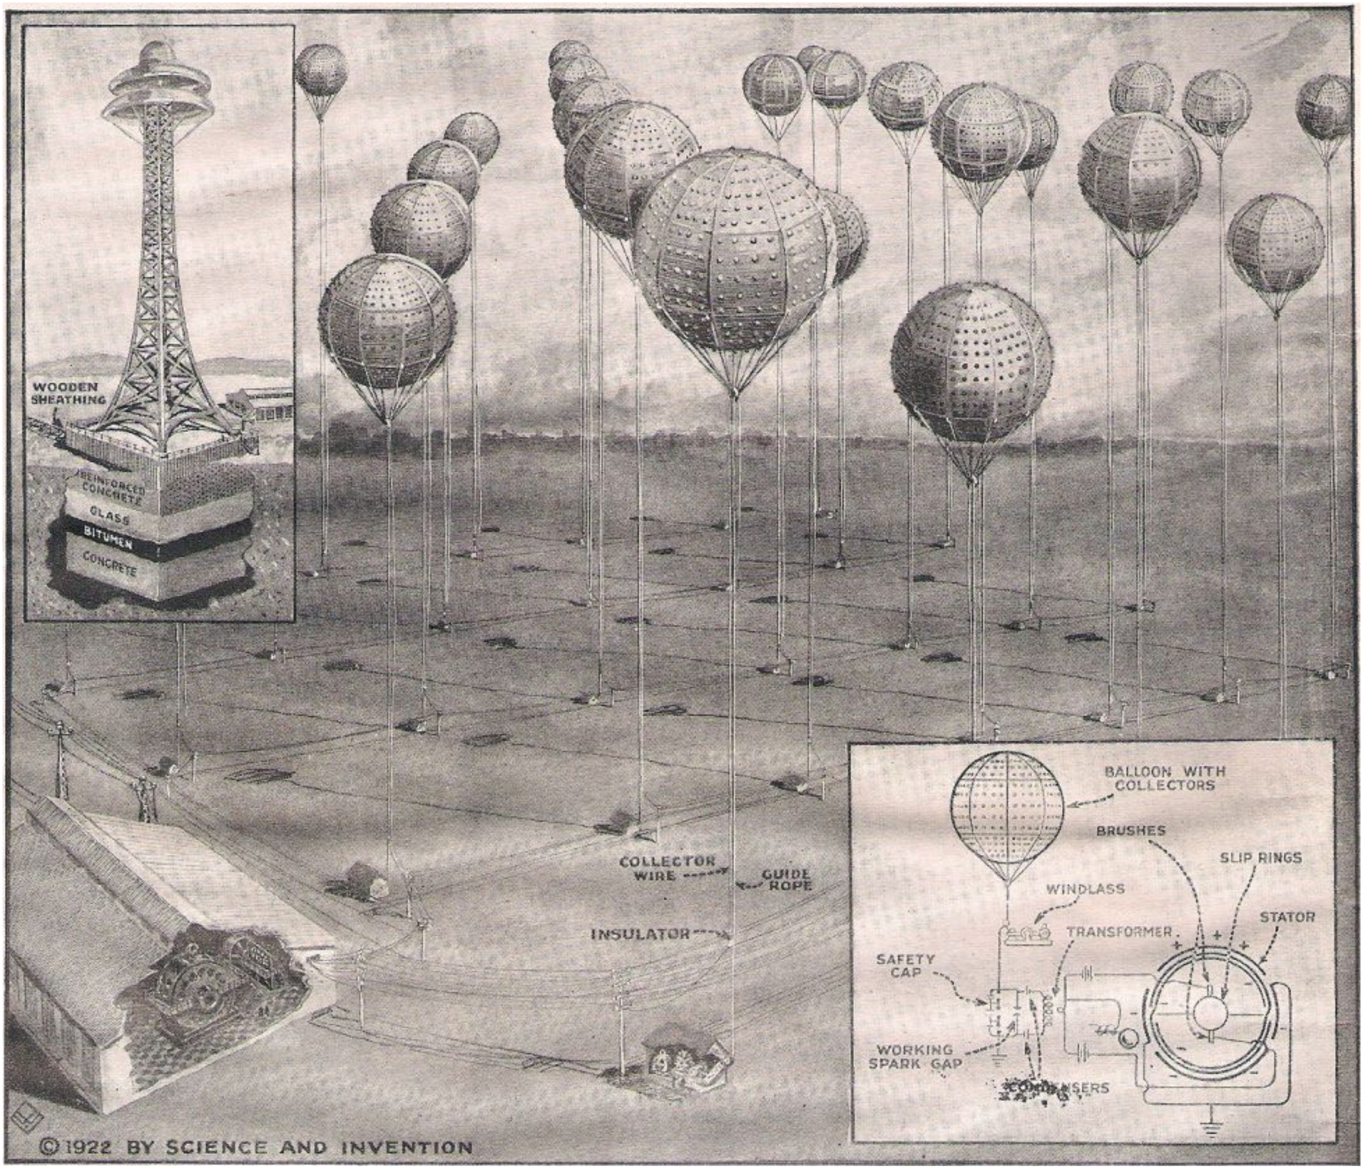
***Science & Invention* (March 1922), page 1006, 1007**

Power from the Air (II)

by

Hugo Gernsback

[For many years electrical engineers have endeavored to devise some means whereby it would become possible to utilize the free electrical energy ever present in the atmosphere, but they were not successful, as every now and then an extra heavy surge of static current would rush down the elevated conductor and endanger the lives of the experimenters, or else destroy the apparatus connected with it. A German engineer has, however, devised the somewhat elaborate scheme here shown in brief, and he has succeeded, at least so his report states, in safely extracting several kilowatts of electrical power from the atmosphere with metallic surfaced balloons, elevated to a height of only 1000 feet.]



We have previously treated of the extraction of electrical energy from the atmosphere. The difference of electric potential in different parts of the atmosphere, and the difference between the upper air and earth make it a tempting proposition to obtain power from atmospheric electricity. The power would take the form of high potential difference with a discharge almost of a static nature. It has long appeared rather doubtful to conservative engineers, if such a source of power should really be available. Yet when we see the lightning flash, it certainly suggests very high power, even though the total of its energy may be small, on account of the small duration of the discharge It is not to the thunder storm that we look for getting power from the atmosphere, as the subject is now being seriously investigated. A German scientist, Hermann Plauson, has published a very elaborate work on this subject, and has investigated the use of kites, balloons and towers, for the utilization of the high potentials existing in the air at different altitudes, and has studied out the construction of motors to be operated by the peculiar type of discharge which will be obtained, if the projects are successfully carried out.

We will first speak of the methods used for collecting electricity from the upper air. The author cites several German patents. One of them shows the use of a kite balloon. The balloon is shown floating in the air, kite fashion, and from it hangs a great net or aerial for the collection of electricity. The conductor from the aerial leads to the ground station; quite an elaborate description is given of the net-work which the patentee proposes to have covered with needle points. A windlass takes in or pays out cable for the balloon, and the patentee claims that by sending the apparatus to a height of about one mile he will have 225,000 volts to draw upon. He then speaks o a battery of 20,000 cells in series, which will use up to 40,000 to 50,000 volts in the charging. This certainly provides for a reasonable large fall of potential.

But our author discards this idea and first suggests something more permanent. He proposes the erection of towers to be in the neighborhood of 1,000 feet high, or about the height of the Eiffel Tower. At the summit he has his collecting aerial. The appliance consists of a number of copper tubes; within each one he proposes to burn gas lamps, whose products of combustion will reach the aerial, a collecting net-work covering the tops of the tubes. One of his apprehensions is that if rain should wet his connections trouble might ensue, so he proposes a protection at the top in the shape of a great bell-like shield, resembling in his terms “a Siamese pagoda”. He also compares the form of the protection to that of a great petticoat insulator. Another of his difficulties is that he must have his tower insulated from the earth. He, therefore describes a complicated foundation for his structure. He proposes first to pour in at the bottom of the excavation a foundation of simple concrete. On this he places a layer of asphalt, and then a layer of cast glass, three to ten feet thick, and then comes a reinforced concrete foundation, to which the metallic foot of the tower is to be anchored. This foundation must rise at least seven feet above the ground level, and is to be boarded in on all sides to protect it from moisture. The author’s idea s to erect a number of these towers connected by a horizontal cable, to which the aerials for collection of potentials are secured.

The author strongly advocates balloons as collectors of the electric power of the air. These he depicts covered with spots. These spots indicate areas to be variously coated and prepared to collect potential from the atmosphere.

In the first place he describes the balloon as made of thin metallic leaf supported by internal ribs. Steel wires silver-plated, copper-plated, or aluminum-coated, run from the balloon to the pendant or junction ring. To this ring the tether cable is attached and runs to an insulated windlass on the surface of the earth. The balloon is to rise to an altitude varying from 300 feet to three miles.

The coating of the spots is to be of the thinnest amalgam, of mercury and gold, or zinc, or even polonium, perhaps only 1/2500 inch thick. All over the upper face of the balloon are numberless metal points. To prepare the needle-like wires, they are collected into bundles and are treated electrolytically in a bath, so as to be dissolved in part. This gives a sharp point and roughened surface, all adapted for collecting the electric energy. The points may be of copper, steel, or some hard metallic alloy. After this corrosion. As it may be termed, the wires are plated with gold or other of the so-called noble metals. It is advised that polonium or radium salts be added to the plating bath.

Dr Plauson devotes many pages of his book to describing his motor. This is a rotary motor including a stator and rotor and its peculiarity is that it contains no coils, develops no electromagnetic field properly speaking, but works by static excitation. One typical arrangement is shown in our illustration. The stator plates and rotor plates are concentric with each other, representing segments of cylinders. The alternation of negative and positive charged plates produces the rotation. In the connections there is included a safety spark gap to take care of dangerous potentials. Inductances and capacities are also used and indicated. It was found that the plates heated, owing to the Foucalt currents, and to overcome this, several methods of subdividing the stator and rotor plates, are described by the author.

The whole subject is quite captivating, and it really seems as if the utilization of the electricity of the air may be almost in sight. It would seem possible to carry out experiments in this direction by means of the Eiffel Tower, but of course, the trouble here is that the tower is grounded, and perfect insulation of the collecting surface is absolutely essential.

And now our author gives us some practical details. He says that on the Finland plains he carried out experiments with a balloon made of aluminum leaf with collecting needles of amalgamated zinc with a radium preparation as an ionizer. The surface of the balloon was sprinkled over with zinc amalgam. It was sent up to a height of 300 meters, early 1,000 feet, and was held by a copper-plated steel wire. A constant current of 1.8 amperes at an average of 400 volts potential difference was obtained. This gave nearly three-quarters of a kilowatt, or close to one horsepower. The collector of the balloon insulated from the earth showed a tension of 42,000 volts. By sending up a second balloon with an antenna to the same height at a distance of 100 meters from the first balloon, a current of over 3 amperes was obtained. Then by putting into the circuit a large condenser, whose capacity was equal to the surface capacity of both balloons, and of the antenna connections, the current rose to 6.8 amperes with about 500 volts mean tension. By the use of these two balloons, he eventually ran up the power to 3.4 kilowatts.

elevation of 350 ft., and these students of natural electrical phenomena have found a very desirable location in the Alps, where they can suspend between one mountain and an adjacent one, a strong iron cable having a length of about 2,000 ft. This cable is about 250 feet above the intervening valley, and from it these daring engineers have suspended a coarsely woven wire net, which serves as an electrical capacity to gather the electricity from the atmosphere. As shown in the pictures, the wire net is supplied with numerous sharp points to aid in collecting the current from the air.

As the accompanying photographs of the actual apparatus and wire cable used last year clearly show, an adjustable spark gap of considerable length is provided. By adjusting this spark gap to various lengths, it is possible to judge the voltage of the discharge which leaps the gap at any moment. Mr. F. W. Peek, Jr., the well-known American worker in the realm of high voltage measurements, together with other engineers, have provided tabulated data and curves for various lengths of both needle and sphere type spark gaps. As one of the accompanying diagrams shows, it is a simple matter to calculate the voltage when a certain length of gap is used. The engineer first checks the length of the gap on the chart; he then follows a line horizontally from the gap length, to where it intersects with the angular line on the chart; and from the point of intersection he looks in a visual line downward to a place where the voltage is given. For needle spark gap measurements, the characteristic curve on the chart is practically a straight line, while for sphere gaps the characteristic curve on the voltage versus gap length, is a curved line. Those interested in high voltage measurements by means of the spark gap method can find the voltage-gap tables and charts in the *Standardization Rules* of the American Institute of Electrical Engineers. According to Mr. Peek's researches, the voltage per foot of atmospheric electrical discharges is about 100,000, while in laboratory measurements with A.C., transformer high potential discharges, the average voltage per foot of spark was found to be about 150,000 volts. The voltage of a lightning flash may

Remarkable cathode ray oscillograph used by Mr. F. W. Peck, Jr., in causing lightning to write its autograph with a pencil of electrons on a photographic film.

easily be 100,000,000 volts, as Mr. Peek has pointed out in one of his scientific papers.

WHY THE EXPERIMENTS ARE BEING MADE

ONE of the main reasons why these dangerous experiments are being carried on by the three young German scientists, whose names we have already learned, is because science believes that with a sufficiently high voltage, it will be possible for man to disintegrate the atom, and in this way make available a tremendous source of power as yet untapped. These experts have calculated that they will be able to obtain electrical energy in sufficient quantity from one of these powerful atmospheric discharges, to equal the Alpha rays obtained from 220 pounds of radium. As we have mentioned before, these experiments are of course fraught with great danger, and for that reason the experimenters seek refuge in a special lightning-proof hut, which is located about 600 ft., from the spark gap. When electrical storms are in the vicinity, it is especially important that the scientists keep within their protected fortress, for otherwise they would very probably be killed by a stray electrical discharge.

One of the peculiar things about this whole line of experiment is that the average layman does not realize perhaps, that there is a high electrical stress in the atmosphere on clear days, as well as when thunder storms are overhead. This fact has been known for a hundred years and more, and many years ago measurements of the various electrical potentials at increasing altitudes, were observed and measured by scientific investigators. There are a number of different ways in which these high electrical potentials found in the atmosphere can be measured; one of these methods involves the use of a calibrated spark gap. In this case the gap is set to a predetermined length, and when a discharge jumps this gap, the engineers know of course from previous experience and measurements, just what voltage is present. Another method of measuring extra high potentials, such as here encountered, requires the use of a static voltmeter, which involves the use of a stationary and of a movable or rotary set of metal plates, forming a condenser, to which an indicating needle is attached. For voltages above 2,000, static voltmeters have been used in a great many American central stations, and they have many desirable and useful characteristics. Of course as the voltage to be measured increases, the space between the quadrant shaped stationary and movable plates is increased and vice versa. The electrostatic field from voltages below 2,000 is not sufficient to warrant the use of a static voltmeter. Another method of measuring high potentials involves the use of the so-called vacuum tube voltmeter.

The general characteristics of the atmospheric electrical discharges, including lightning, have been measured and recorded by one of the newest scientific instruments, known as the cathode ray oscillograph. By means of this quite remarkable, high voltage scientific apparatus. Mr. Peck, one of the well-known General Electric Company staff of research engineers, has made some very interesting and remarkable discoveries concerning the nature of natural electrical discharges, particularly of lightning discharges. Many people will probably wonder why Mr. Peek and some of his colleagues in the engineering profession, including the three daring German students, Messrs. Brasch, Lange and Urban, play with such dangerous electrical discharges, and why they are at all interested in them. We explained previously why the German savants are intent on finding out all they can about these tremendous voltages obtained from the atmosphere, while Mr. Peck, we may say, also has a very practical reason for carrying on experiments with these death-dealing bolts of Thor. Mr. Peek has been for many years intent on finding out what causes the huge insulators on long distance, high potential transmission lines to break down when electrical storms break loose over these regions.

Atmospheric Electricity Research
[Excerpts]

In the nineteenth and early twentieth centuries, a large number of researchers investigated ways to extract electrical power from the Earth's ambient electric field.

The leader in this field was Dr Hermann Plauson who in the 1920s succeeded in generating significant quantities of electrical power comparable with modern solar photovoltaic systems of a similar scale...

The leader in this field before the Second World War appears to have been Dr Hermann Plauson. Dr Plauson was an Estonian citizen who lived in Hamburg and Switzerland. He carried out experiments in Finland with aerostats manufactured from magnesium-aluminium alloy, covered with electrolytically deposited needles. The needles were further doped with a radium compound to increase local ionisation of the air. (This was the era in which the hands of watches were hand painted with radium to make them luminous in the dark). Zinc amalgam patches were also painted onto the aerostats. Plauson obtained a power output of between 0.72kW and 3.4kW from one and two aerostats 300m above ground level. Dr Plauson filed patents in the USA, Great Britain and Germany in the 1920s. His book "Gewinnung und Verwertung der Atmosphärischen Elektrizität" is the most detailed known account of the technology.

Other atmospheric electricity researchers contemporary to Dr Plauson included Walter Pennock and MW Dewey in the USA, Andor Palencsar in Hungary and Dr Heinrich Rudolph in Germany. Hippolyte Charles Vion in Paris predated them all, putting forward proposals in the 1850s and 1860s.

Heinrich Rudolph made an interesting contribution to the design of the aerostat collectors. In 1898 he designed an elliptical aerostat made up of faceted surfaces to minimise the effect of wind. The design bears a strong resemblance to Northrop's 2003 UCARS unamnned helicopter UAV project. The design uses the Coanda Effect to help keep the aerostat on station and minimise wind effects.

In recent times, the only person who seems to have been active in this field is Dr Oleg Jefimenko. Dr Jefimenko carried out experiments on driving electrostatic motors from the Earth's electric field in the 1970s and has recently called for research into the neglected field of electrostatic motors to be renewed.

MIR's Research Programme

Since 1997 we have been carrying out theoretical research into conversion of atmospheric electricity into useable electrical power.

From a low level (5m high) simple zinc antenna we are able to obtain sufficient charge to light a number of white power LEDs. Further experimental investigations with metallic aerostat collectors and cavity resonant slow wave antennae concepts are ongoing...

Conversion of Atmospheric Electric Energy

(9 June 1925)

Hermann PLAUSON

Be it known that I, Hermann Plauson, Estonian subject, residing in Hamburg, Germany, have invented certain new and useful improvements in the Conversion of Atmospheric Electric Energy, of which the following is a specification.

Methods of obtaining atmospheric electricity by means of metallic nettings set with spikes which are held by means of ordinary or anchored kite balloons made of fabric and filled with hydrogen, are in theory already known. Atmospheric electricity obtained in this way has been suggested to be used in the form of direct current for the charging of accumulators. This knowledge however is at present only theoretical as the conversion in practice has hitherto been a failure. No means are known of protecting the apparatus from destruction by lightning. The balloons used for collecting the charge must also me be made of very large size in order to be able to support the weight of the metallic netting and the heavy cable connections.

Instead of using heavy metallic netting as collectors attached to single air ballons of non-conducting materials which are liable to be torn and are permeable to the gas, it is proposed to use metallic balloon collectors which have the following important advantages ---

(a) The metallic cases are impenetrable to helium and hydrogen; they also represent large metallic weather-proof collecting surfaces.

(b) Radio active means the like may be easily applied internally or externally; whereby the ionization is considerable increased and therewith also the quantity of atmospheric electricity capable of being collected.

(c) Such balloon collectors of light metal do not require to be of large size as they have to carry only their own moderate weight, and that of the conducting cable or wire.

(d) The entire system therefore offers little surface for the action of storm and wind and is resistant and stable.

(e) Each balloon can be easily raised and lowered by means of a winch so that all repairs, recharging and the like can be carried out without danger during the operation.

It is further proposed to use a collecting aerial network of several separate collectors spread out in the air above the earth, which collectors are interconnected by electrical conductors.

According to this invention charges of atmospheric electricity are not directly converted into mechanical energy, and this forms the main difference from previous inventions, but the static electricity which runs to earth through aerial conductors in the form of direct current of very high voltage and low current strength is converted into electro-dynamic energy in the form of high frequency vibrations. Many advantages are thereby obtained and all disadvantages avoided.

The very high voltage of static electricity of a low current strength can be converted by this invention to voltages more suitable for technical purposes and of greater strength. By the use of closed oscillatory circuits it is possible to obtain electromagnetic waves of various amplitude and thereby to increase the degree of resonance of such current. Such resonance allows various values of inductance to be chosen whereby again the governing of the starting and stopping of machines driven thereby by simply tuning the resonance between coils of the machine and the transformer circuit forming the resonance can easily be obtained. Further, such currents have the property of being directly available for various uses, even without employing them for driving motors, of which there may be particularly mentioned, lighting, production of heat and use in electro-chemistry.

Further, with such currents a series of apparatus may be fed without direct current supply through conductors and also the electro-magnetic high frequency currents may be converted by means of special motors adapted for electro-magnetic oscillations into mechanical energy, or finally converted by special machines into alternating current of low frequency or even into direct current of high potential.

The invention is more particularly described with reference to the accompanying diagrams in which: ---

Fig. 1.

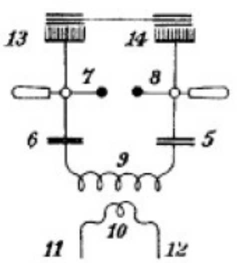

Fig. 2.

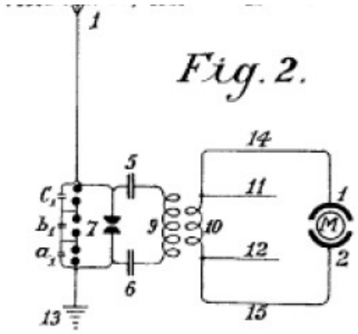

Figure 1 illustrates a simple diagram for converting static electricity into dynamic power of a high number of oscillations. For the sake of clearness in the drawings an influence machine is assumed to be employed and not an aerial antenna. 13 and 14 are combs for collecting the static electricity of the influence machine. 7 and 8 are spark discharging electrodes. 5 and 6 are condensers, 9 an inductive primary coil, 10 secondary coil, 11 and 12 ends of conductors of the secondary coil 10. When the disc of the static influence machine is rotated by mechanical means, the combs collect the electric charges one the positive and the other the negative, and charge the condensers 5 and 6 until such a high potential is formed across the spark gap 7-8, that the spark gap is jumped. As the spark gap 7-8 forms a closed circuit with condensers 5 and 6, and inductive resistance 9, as is well known, waves of high frequency electromagnetic oscillations will pass in this circuit.

The high frequency of the oscillations produced in the primary circuit induces waves of the same periodicity in the secondary circuit. Thus in the primary circuit electromagnetic oscillations are formed by the passage of the spark over the spark gap and these waves are maintained by fresh charges of static electricity.

By suitably selecting the ratio between the number of the coils in the primary and secondary circuits with regard to a correct application of the co-efficients of resonance (especially, inductance and resistance) the high voltage of the primary circuit may be suitably converted into low voltage and high current strength.

When the oscillatory discharges in the primary circuit becomes weaker or entirely cease, the condensers are charged again by the static electricity until the accumulated charge again breaks down the spark gap. All this is repeated as long as electricity is produced by the static machine employing mechanical energy.

An elementary form of the invention is shown in Figure 2 in which two spark gaps in parallel are used one of which may be termed the working gap 7 in Figure 2, whilst the second serves as a safety device for excess voltage and consists of a larger number of spark gaps than the working section, which gaps are arranged in series and are bridged by very small capacities as is illustrated in a, b, c, Figure 2 which allow of uniform sparking in the safety section.

In Figure 2 A is the aerial antenna for collecting charges of atmospheric electricity. 13 is the earth connection of the second part of the spark gap, 5 and 6 are condensers, 9 a primary coil. Now when through the aerial A the positive atmospheric electricity seeks to combine with the negative charge to earth, this is prevented by (the air gap between) the spark gaps. The resistance of the spark gap 7 is, as shown in the drawings, lower than that of the other safety section which consists of three spark gaps connected in series, and consequently a three times greater air resistance is offered by the latter.

So long, therefore, as the resistance of the spark gap 7 is not overloaded, so that the other spark gaps have an equal resistance with it the discharges take place only over spark gap 7. Should however the voltage be increased by and influences so that it might be dangerous for charging the condensers 5 and 6 or for the coil insulation 9 and 10 in consequence of break down, by a correct regulation of this spark gap the second spark gap can discharge free from inductive effects direct to earth without endangering the machine.

Without this second spark gap, arranged in parallel having a higher resistance than the working spark gap it is impossible to collect and render available large quantities of electrical energy.

The actions of this closed oscillation circuit consisting of spark gap 7, two condensers 5 and 6, primary coil 9, and also secondary coil 10 is exactly the same as the one described in Figure 1 with the arrangement of the static induction machine with the only difference that here the second spark gap is provided. The electromagnetic high frequency alternating current obtained can be tapped off from the conductors 11 and 12 for lighting and heating purposes. Special kinds of motors adapted for working with these peculiar electrical charges may be connected at 14 and 15 which can work with static electricity charges or with high frequency oscillations.

In addition to the use of spark gaps in parallel a second measure of security is also necessary for taking off the current. This precaution consists according to this invention, in the introduction of and method of connecting certain protective electromagnets or choking coils in the aerial circuit as shown by S in Figure 3.

A single electromagnet only having a core of the thinnest possible separate laminations is connected with the aerial.

In the case of high voltages in the aerial network or at places where there are frequent thunder storms, several such magnets may however be connected in series.

In the case of large units or plants several electromagnets can be employed in parallel or in series parallel.

The windings of these electromagnets may be simply connected in series with the aerials. In this case the winding preferably consists of several thin parallel wires, which make up together, the necessary section.

The winding may be made of primary and secondary windings in the form of a transformer. The primary windings will be then connected in series with the aerial network, and the secondary winding more or less short-circuited over a regulating resistance or an induction coil. In the latter case it is possible to regulate to a certain extent the effect of the choking coils. In the further description of the connecting and constructional diagrams the aerial electromagnet choke coil is indicated by a simple ring S.

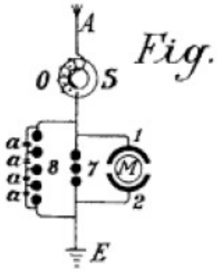

Fig. 3.

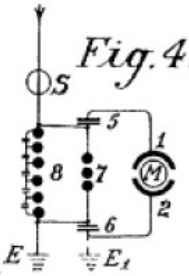

Fig. 4.

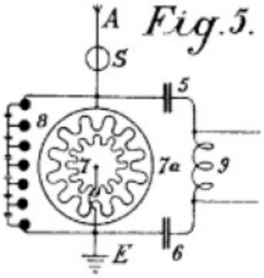

Fig. 5.

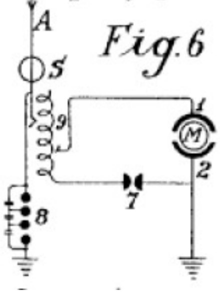

Fig. 6

Figure 3 shows the simplest way of converting atmospheric electricity into electromagnetic wave energy by the use of special motors adapted for high oscillatory currents or static charges of electrical energy. Recent improvements in motors for working with static charges and motors working by resonance, that is to say, having groups of tuned electromagnetic cooperating circuits render this possible but such do not form part of the present invention.

A motor adapted to operate with static charges will for the sake of simplicity be diagrammatically indicated by the two semicircles 1 and 2 and the rotor of the motor by a ring M (Figure 3). A is a vertical aerial or aerial network. S the safety choke or electromagnet with coil O as may be seen is connected with the aerial A. Adjacent the electromagnet S the aerial conductor is divided into three circuits, the circuit 8 giving the safety spark gap, the circuit 7 with the working spark gap, and then a circuit including the stator terminal 1, the rotor and stator terminal 2 at which a connection is made to the earth wire. The two spark gaps are also connected metallically with the earth wire. The method of working these diagrams is as follows:

The positive atmospheric electric charge collected tends to combine with the negative electricity (or earth electricity) connected with the earth wire. It travels along the aerial A through the electromagnet S without begin checked as it flows in the same direction as the direct current. Further, its progress is arrested by two sparks gaps placed in the way and the stator condenser surfaces. The stator condenser surfaces are charged until the charge is greater than the resistance of the spark gap 7, whereupon a spark springs over the spark gap 7 and an oscillatory charge is obtained as by means of the motor M, stator surfaces 1 and 2, and spark gap 7, a closed oscillation circuit is obtained for producing the electromagnetic oscillations. The motor here forms the capacity and the necessary inductance and resistance, which, as is well known, are necessary for converting static electricity into electromagnetic wave energy.

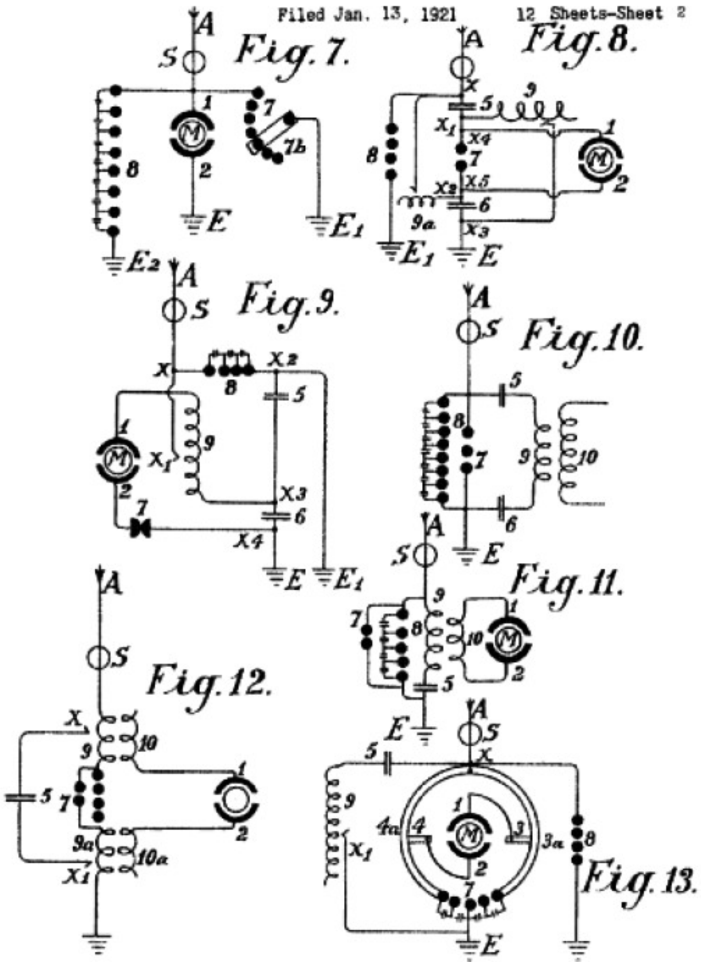
The discharge formed are converted into mechanical energy in special motors and cannot reach the aerial network by reason of the electromagnet or choke. If, however, when a spark springs over the spark gap 7 a greater quantity of atmospheric electricity tends to flow to earth, a counter voltage is induced in the electromagnet, which is greater the more rapidly and strongly the flow of current direct to the earth is. By the formation of this opposing voltage a sufficiently high resistance is offered to the flow of atmospheric electricity direct to earth to prevent a short circuit with the earth.

The circuit containing spark gap 8 having a different wave length which is not in resonance with the natural frequency of the motor, does not endanger the motor and serves as security against excess voltage, which, as practical experiments have shown, may still arise in certain cases, but can be conducted direct to earth through this spark gap.

In the diagram illustrated in Figure 4 the spark gap 7 is shunted across condensers 5 and 6 from the motor M. This construction affords mainly a better insulation of the motor against excess voltage and a uniform excitation through the spark gap 7.

In Figure 5 a diagram is illustrated for transforming large current strengths which may be employed direct without motors, for example, for lighting or heating purposes. The main difference is that here the spark gap consists of as star shaped disk 7 which can rotate on its own axis and is rotated by a motor opposite similarly fitted electrodes 7a. When separate points of stars face one another, discharges take place, thus forming an oscillation circuit over condensers 5 and 6, and inductance 9 for oscillatory discharges. It is evident that a motor may also be directly connected to the ends of the spiral 9.

The construction of the diagram shown in Figure 6 permits of the oscillation circuit of the motor being connected with an induction coil/ Here a regulating inductive resistance is introduced for counter-acting excess voltages in the motor. By cutting the separate coils 9 (coupled inductively to the aerial) in or out the inductive action on the motor may be more or less increased or variable aerial action may be exerted on the oscillation circuit.



In Figure 7 the oscillation circuit is closed through the earth (E and E1). The spark gap 7 may be prolonged or shortened by more or fewer spark gaps being successively connected by means of a contact arm 7b.

Diagram 8 shows a unipolar connection of the motor with the aerial network. Here two oscillation circuits are closed through the same motor. The first oscillation circuit passes from aerial A through electromagnet S, point *x*, inductance 9a to the earth condenser 6 and further, over spark gap 7 to the aerial condenser 5 and back to *x*. The second oscillation circuit starts from the aerial condenser 5 at the point x^1 over the inductance 9 to the earth condenser 6 at the point x^3 and through the condenser 6 over the spark gap 7 back to x^1. The motor itself is inserted between the two points of the spark gap 7. From this arrangement slightly damped oscillation wave currents are produced.

In the diagram illustrated in Figure 9 a loosely coupled system of connections is illustrated which is assumed to be for small motors for measuring purposes. A indicates the aerial conductor, S the electromagnet in the aerial conductor, 9 the inductance, 7 the spark gap, 5 and 6 condensers, E the earth, M the motor, and 1 and 2 stator connections of the motor. The motor is directly metallically connected with the oscillation circuit.

In Figure 10 a purely inductive coupling is employed for the motor circuit. The motor is connected with the secondary wire 10 as may be seen in Figure 11 in a somewhat modified diagram connection. The same applies to the diagram of Figure 12.

The diagrams hitherto described preferably allow of motors of small and medium strength to be operated. For large aggregates, however, they are too inconvenient as the construction of two or more oscillation circuits for large amounts of energy is difficult; the governing is still more difficult and the danger in switching on or off is greater.

A means of overcoming such difficulties is shown in Figure 13. The oscillation circuit here runs starting from the point x over condenser 5, variable inductance 9, spark gap 7, and the two segments (3a and 4a) forming arms of a Wheatstone bridge, back to x, If the motor is connected by brushes 3 and 4 transversely to the two arms of the bridge as shown in the drawings, electromagnetic oscillations of equal sign are induced in the stator surfaces 1 and 2 and the motor does not revolve. If however the brushes 3 and 4 are moved in common with the conducting wires 1 and 2 which connect the brushes with the stator poles a certain alteration or displacement of the polarity is obtained and the motor commences to revolve.

The maximum action will result if one brush 3 comes on the central sparking contact 7 and the other brush 4 on the part *x*. They are however, usually in practice not brought on the central contact 7 but only held in the path of the bridge segments 4a and 3a in order not to connect the spark gaps with the motor oscillation circuit.

As however, the entire oscillation energy can thereby not act on the motor it is better to carry out the same system according to the diagram 14. The diagram 14 differs from the foregoing only by the motor not being directly metallically connected with the segments of the commutator, but only a primary coil 9 which induces in a secondary coil 10, current which feeds the motor M and takes the place of the rotor. By this arrangement a good transforming action is obtained, a loose coupling and also an oscillation circuit without a spark gap.

In Figure 15 the motor is not purely inductive as in 14, but directly metallically branched off from the primary coil (at x and x^1) after the principle of the auto-transformer.

In Figure 16 instead of an inductance a condenser 6 is in similar manner, and for the same object inserted between the segments 3a and 4a. This has the advantage that the segments 3a and 4a need not be made of solid metal but may consist of spiral coils whereby a more exact regulation is possible and further motors of high inductance may be employed.

The arrangements of Figures 17, 18 and 19 may be employed for use with resonance and particularly with induction condenser motors; between the large stator induction condenser surfaces, small reversing pole condenser surfaces, mall reversing pole condensers are connected, which, as may be seen from Figures 17, 18 and 19 are led together to earth. Such reversing poles have the advantage that with large quantities of electrical energy the spark formation between the separate oscillation circuits ceases.

Figure 19 shows a further method which prevents electromagnetic oscillations of high number of alternations formed in the oscillation circuit striking back to the aerial conductor. It is based on the well known principle that a mercury lamp, one electrode of which is formed of mercury, the other of solid metal such as steel allows an electric charge to pass in only one direction from the mercury to the steel and not vice versa. The mercury electrode of the vacuum tube N is therefore connected with the aerial conductor and the steel electrode with the oscillation circuit. From this it results that charges can pass only from the aerial through the vacuum tube to the oscillation circuit, but not vice versa. Oscillations which are formed on being transformed in the oscillation circuit cannot pass to the aerial conductor.

In practice these vacuum tubes must be connected behind an electromagnet as the latter alone affords no protection against the danger of lightning.

As regards the use of spark gaps, all arrangements as used for wireless telegraphy may be used. Of course the spark gaps in large machines must have a sufficiently large surface. In very large stations they are cooled in liquid carbonic acid or better still in liquid nitrogen or hydrogen; in most cases the cooling may also take place by means of liquefied low homologues of the metal series or by means of hydrocarbons the freezing point of which lies at between –90° C and –40° C. The spark gap casing must also be insulated and be of sufficient strength to be able to resist any pressure which may arise. Any undesirable excess super-pressure which may be formed must be automatically let off. I have employed wit very good results mercury electrodes which were frozen in liquid carbonic acid, the cooling being maintained during the operation from the outside through the walls.

Figure 20 is one of the simplest forms of construction of an aerial network in combination with collectors, transformers and the like illustrated diagrammatically. E is here the earth wire, 8 the safety spark gap, 7 the working spark gap, 1 and 2 the stator surfaces of the motor, 5 a condenser battery, S the protective magnet which is connected with the coil in aerial conductor, A^1 to A^{10} aerial antennae with collecting balloons, N horizontal collecting or connecting wire from which, to the center a number of connections run.

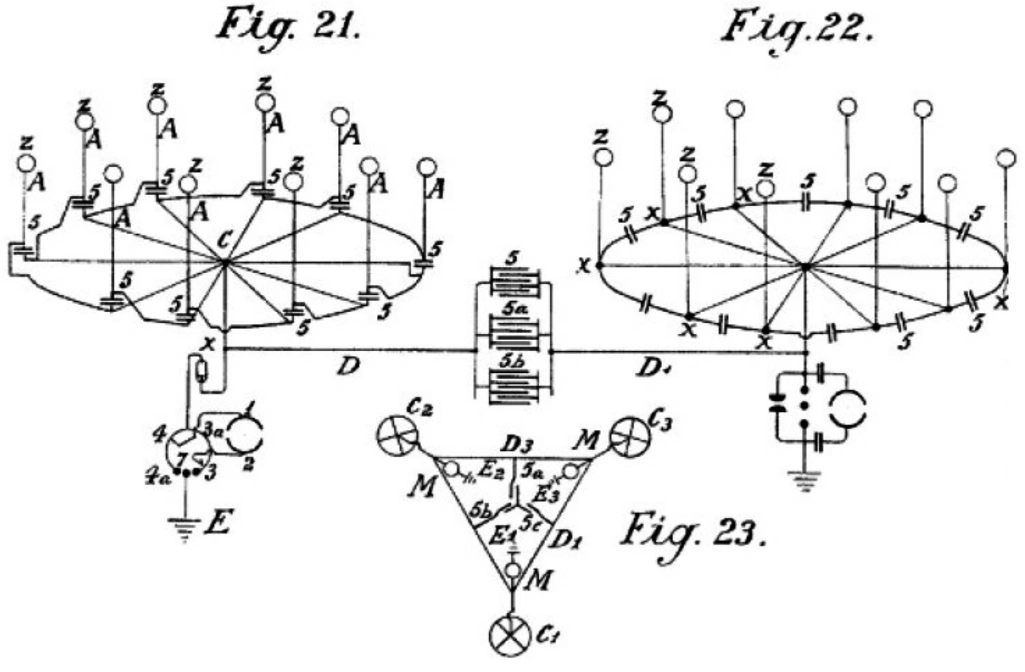
The actual collectors consist of metal sheaths preferably made of an aluminum magnesium alloy, and are filled with hydrogen or helium and are attached t copper plated steel wires. The size of the balloon is selected so that the actual weight of the balloon and the weight of the conducting wire is supported thereby. On top of the balloon aluminum spikes, made and gilded in a special manner hereinafter described, are arranged in order to produce a conductor action. Small quantities of radium preparations, more particularly polonium-ionium or meso-thorium preparations considerably increase the ionization, and therewith the action of these collectors.

In addition to metal balloons, fabric balloons which are superficially metal coated according to Schoop's metal spraying process, may also be employed. A metallic surface may also me produced by lacquering with metallic bronzes, preferably according to Schoop's spraying process or lacquering with metallic bronze powders in two electrical series of widely different metals, because thereby the collecting effect is considerably increased.

Instead of the ordinary round balloons, elongated cigar shaped ones may be employed. In order also to utilize the frictional energy of the wind, patches or strips of non-conducting substances which produce electricity by friction, may be attached to the metalized balloon surfaces. The wind will impart a portion of its energy in the form of frictional electricity, to the balloon casing, and thereby the collecting effect is substantially increased.

In practice however, very high towers (up to 300 meters is fully admissible) may be employed as antennae. In these towers copper tubes rise freely further above the top of the tower. A gas lamp secured against the wind is then lit at the point of the copper tube and a netting is secured to the copper tube over the flame of this lamp to form a collector. The gas is conveyed through the interior of the tube up to the summit. The copper tube must be absolutely protected from moisture at the place at which it enters the tower and also rain must be prevented running down the walls of the tower which might lead to a bad catastrophe. This is done by bell shaped enlargements which expand downwards, being arranged in the tower in the form of high voltage insulators of Siamese pagodas.

Special attention must be devoted to the foundations of such towers. They must be well insulated from the ground, which may be obtained by first embedding a layer of concrete in a box form to a sufficient depth in the ground and inserting in this an asphalt lining and then glass bricks cast about 1 or 2 meters in thickness. Over this in turn there is a ferro-concrete layer in which alone the metal foot of the tube is secured. This concrete block must be at least 2 meters from the ground and be fully protected at the sides by a wooden covering, from moisture. In the lower part of the tower a wood or glass house for the large condenser batteries or for the motors may be constructed. In order to lead the earth connection to the ground water, a well insulated pit constructed of vitreous brick, must be provided. Several such towers are erected at equal distances apart and connected with a horizontal conductor. The horizontal connecting wires may either run directly from tower to tower or be carried on bell shaped insulators similar to those in use for high voltage conductors. The width of the network may be of any suitable size and the connection of the motors can take place at any suitable places.



In order to collect large quantities of electricity with few aerials it is well to provide the aerial conductor with batteries of condensers as shown in Figures 21 and 22. In Figure 21 the batteries of condensers 5 are connected on the one hand with the aerial electricity collectors Z by the aerial conductor A, and on the other hand interconnected in series with an annular conductor from which horizontal conductors run to the connecting points C to which the earth wire is connected.

Figure 22 shows a similar arrangement, Should two such series of antennae rings be shown by a voltmeter to have a large difference of potential (for example, one in the mountains and one in the plain) or even of different polarity these differences may be compensated for by connecting sufficiently large condenser batteries (5, 5a, 5b) by means of Maji star conductors D and D^1. In Figure 23 a connection of three such rings of collectors to form a triangle with a central condenser battery is illustrated.

The condenser batteries of such large installations must be embedded in liquid gases or in liquids freezing at very low temperatures. In such cases a portion of the atmospheric energy must be employed for liquefying these gases. It is also preferable to employ pressure. By this means the condenser surfaces may be diminished, and still allow for large quantities of energy to be stored, secure against breakdown. For smaller installation the immersing of the condensers in well-insulated oil or the like, suffices. Solid substances on the other hand cannot be employed as insulators.

The arrangement in the diagrams hitherto described was always such that the condenser batteries were connected with both poles directly to the aerial condensers. An improved diagram of the connections for obtaining atmospheric electricity for the condenser batteries has however, been found to be very advantageous. This arrangement consists in that they are connected only by one pole (unipolar) to the collecting network. Such a method of arrangement is very important, as by means of it a constant current and an increase of the normal working pressure or voltage is obtained. If for example a collecting balloon aerial which is allowed to rise to a height of 300 meters, shows 40,000 volts above earth voltage, in practice it has been found that the working voltage (with a withdrawal of the power according to the method hereinbefore described by means of oscillating spark gaps and the like) is only about 400 volts. If however, the capacity of the condenser surfaces be increased, which capacity in the above mentioned case was equal to that of the collecting surface of the balloon aerials, to double the amount, by connecting the condenser batteries with only one pole, the voltage rises under an equal withdrawal of current up to and beyond 500 volts. This can only be ascribed to the favorable action of the connecting method.

In addition to this substantial improvement it has also been found preferable to insert double inductances with electromagnets and to place the capacities preferably between two such electromagnets. It has also been found that the useful action of such condensers can be further increased if an induction coil be connected as inductive resistance to the unconnected pole of the condenser, or still better if the condenser itself be made as an induction condenser. Such a condenser may be compared with a spring which when compressed carries in itself accumulated force, which it again gives off when released. In charging, a charge with reversed sign is formed at the other free condenser pole, and if through the spark gap a short circuit results, the accumulated energy is again given back since now new quantities of energy are induced at the condenser pole connected with the conductor network, which in fact charges with opposite signs to that at the free condenser pole. The new induced charges have of course the same sign as the collector network. The whole voltage energy in the aerial is thereby however increased. In the same space of time larger quantities of energy are accumulated than is the case without such inserted condenser batteries.

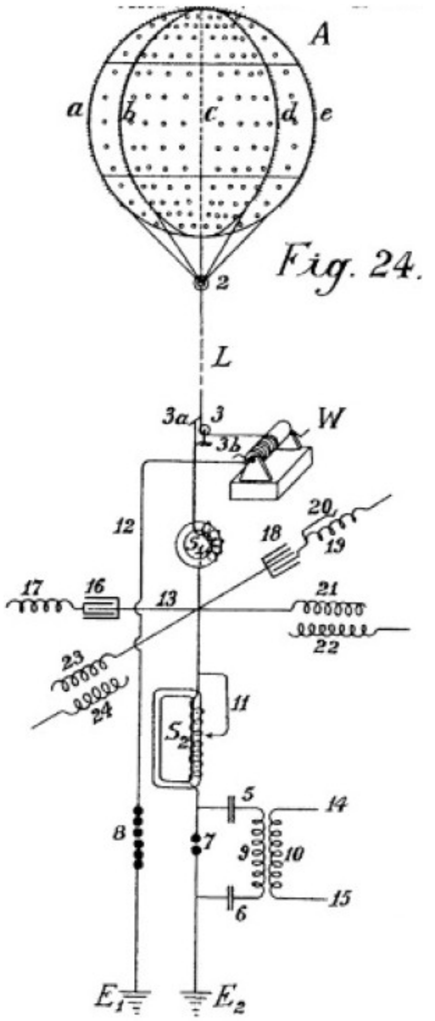


Fig. 24.

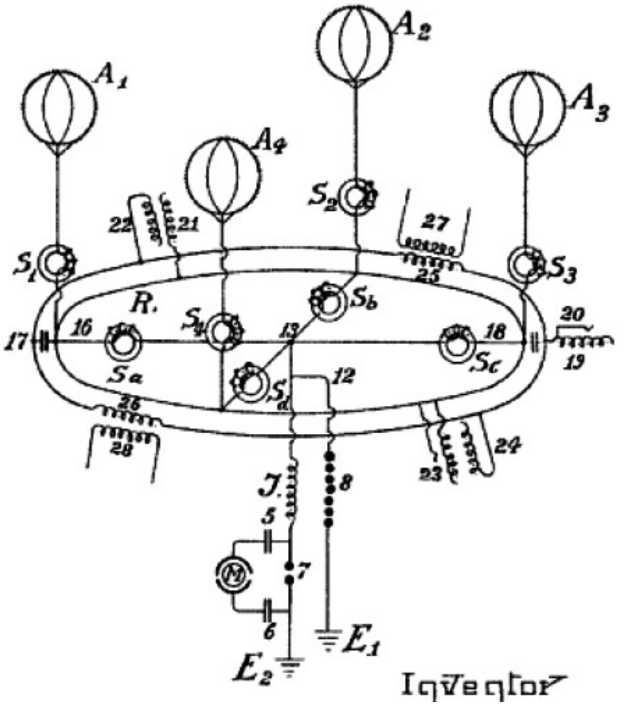
Fig. 25.



In Figures 24 and 25 two different diagrams of connections are more exactly illustrated, Figure 24 shows a collecting balloon and the diagram of the connections to earth. Figure 25 shows four collecting balloons and the parallel connection of the condenser batteries belonging thereto.

A is the collecting balloon made of an aluminum magnesium alloy (electron metal, magnalium) of a specific gravity of 1.8 and a thickness of plate 0.1 to 0.2 mm. Insider there are eight strong vertical ribs of T-shaped section about 10 to 20 mm in height and about 3 mm in thickness with the projecting part directed inwards (indicated by a, b, c, d and so forth); they are riveted together to form a firm skeleton and are stiffened in a horizontal direction by two cross ribs. The ribs are further connected with one another internally and transversely by means of thin steel wires, whereby the balloon obtains great power of resistance and elasticity. Rolled plates of 0.1 to 0.2 mm in thickness made of magnalium alloy are then either soldered or riveted on this skeleton so that a fully metallic casing with smooth external surface is obtained Well silvered or coppered aluminum plated steel wires run from each rib to the fastening ring 2. Further, the coppered steel hawser L preferably twisted out of separate thin wires (shown in dotted lines in Figure 24) and which must be long enough to allow the balloon to rise in the desired height, leads to a metal roller or pulley 3 and from thence to a winch W, well insulated from the earth. By means of this winch, the balloon, which is filled with hydrogen, or helium, can be allowed to rise to a suitable height (300 to 5000 meters) and brought to the ground for recharging or repairs.

The actual current is taken directly through a friction contact from the metal roller 3 or from the wire, or even from the winch or simultaneously from all three by means of brushes (3, 3a and 3b). Beyond the brushes the conductor is divided, the paths being: --- firstly over 12 to the safety spark gap 8, from thence to the earth conductor E^1, and secondly over electromagnet S^1, point 13, to a second loose electromagnet having an adjustable coil S^2, then to the spark gap 7 and to the second earth conductor E^2. The actual working circuit is formed through the spark gap 7, condensers 5 and 6, and through the primary coil 9; here the static electricity formed by oscillatory discharges is accumulated and converted into high frequency electromagnetic oscillations. Between the electromagnets S^1 and S^2 at the crossing point 13, four condenser batteries are introduced which are only indicated diagrammatically in the drawings each by one condenser. Two of these batteries (16 and 18) are made as plate condensers and prolonged by regulating induction coils or spirals 17 and 19 while the two others (21 and 23) are induction condensers. As may be seen from the drawings each of the four condenser batteries 16, 18, 21 and 23 is connected by only one pole to the aerial or to the collector conductor. The second poles 17, 19, 22 and 24 are open. In the case of plate condensers having no inductive resistance an induction coil is inserted. The object of such a spiral or coil is the displacement of phase by the induction current by 1/4 periods, whilst that of the charging current of the condenser poles which lie free in the air, works back to the collector aerial. The consequence of this is that in discharges in the collector aerial the back inductive action of the free poles allows a higher voltage to be maintained in the aerial collecting conductor than would otherwise be the case. It has also been found that such a back action has an extremely favorable effect on the wear of the contacts. Of course the inductive effect may be regulated at will within the limits of the size of the induction coil, the length of the coil in action being adjustable by means of wire connection without induction (see Figure 24, No. 20).

S^1 and S^2 may also be provided with such regulating devices in the case of S^2 (illustrated by 11). If excess voltage be formed it is conducted to earth through the wire 12 and spark gap 8 or through any other suitable apparatus, since this formation would be dangerous for the other apparatus.

The small circles on the collector balloon indicate places at which zinc amalgam or gold amalgam or other photoelectric acting metals in the form of small patches in extremely thin layers (0.01 to 0.05 mm in thickness) are applied to the entire balloon as well as in greater thickness to the conducting network. The capacity of the collector is thereby considerably strengthened at the surface. The greatest possible effect in collecting may be obtained by polonium amalgams and the like. On the surface of the collector balloon metal points or spikes are also fixed along the ribs, which spikes serve particularly for collecting the collector charge. Since it is well known that the resistance of the spikes is less the sharper the spike is, for this purpose it is therefore extremely important to employ as sharp spikes as possible. Experiments made as regards these have shown that the formation of the body of the spike or point also plays a large part, for example, spikes made of bars or rollers with smooth surface, have a many times greater point resistance as collector accumulator spikes than those with rough surfaces. Various kinds of spike bodies have been experimented with for the collector balloons hereinbefore mentions. The best results were given by spikes which were made in the following way. Fine points made of steel, copper, nickel, or copper and nickel alloys, were fastened together in bundles and then placed as anode with the points in a suitable electrolyte (preferably in hydrochloric acid or muriate of iron solutions) and so treated with weak current at 2 to 3 volts pressure. After 2 to 3 hours according to the thickness of the spikes or pins the points become extremely sharp and the bodies of the spikes have a rough surface. The bundle can then be removed and the acid washed off with water. The spikes are then placed as cathode in a batch consisting of solution of gold, platinum, iridium, palladium or wolfram salts or their compounds and coated a the cathode galvanically with a thin layer of precious metal, which must however be sufficiently firm to protect them from atmospheric oxidation.

Such spikes act at a 20-fold lower voltage almost as well as the best and finest points made by mechanical means. Still better results are obtained if polonium or radium salts are added to the galvanic bat when forming he protective layer or coating. Such pins have a low resistance at their points and even at one volt and still lower pressures have an excellent collector action.

In Figure 24 the three unconnected poles are not connected with one another in parallel. That is quite possible in practice without altering the principle of the free pole. It is also preferable to interconnect in parallel to a common collector network, a series of collecting aerials.

Figure 25 shows a diagram for such an installation. A^1, A^2, A^3, A^4 are four metal collector balloons with gold or platinum coated spikes which are electrolytically made in the presence of polonium emanations or radium salts, which spikes or needles are connected over four electromagnets S^1, S^2, S^3, S^4, through an annular conductor R. From this annular conductor four wires run over four further electromagnets Sa, Sb, Sc, Sd, to the connecting point 13. There the conductor is divided, one branch passing over 12 and the safety spark gap 8 to the earth at E^1, the other over inductive resistance J and working spark gap 7 to the earth at E^2. The working circuit, consisting of the condenser 5 and 6 and a resonance motor M, such as hereinbefore described, is connected in proximity round the sparking gap section 7.

Instead of directly connecting the condenser motor of course the primary circuit for high frequency oscillatory current may also be inserted.

The condenser batteries are connected by one pole to the annular conductor R and can be either inductionless (16 and 18) or made as induction condensers as shown by 21 and 23. The free poles of the inductionless condensers are indicated by 17 and 19, those of the induction condensers by 22 and 24. As may be seen from the drawings all these poles 17, 22, 19, 24 may be interconnected in parallel through a second annular conductor without any fear that thereby the principle of the free pole connection will be injured. In addition to the advantages already set forth the parallel connection also allows of an equalization of the working pressure in the entire collector network. Suitable constructed and calculated induction coils 25 and 26 may also be inserted in the annular conductor of the free poles, by means of which a circuit may be formed in the secondary coils 27 and 28 which allows current produced in this annular conductor by fluctuations of the charges of the like appearances to be measured or otherwise utilized.

According to what has been hereinbefore stated separate collector balloons may be connected at equidistant stations distributed over the entire country, either connected directly with one another metallically or by means of intermediate suitably connected condenser batteries through high voltage conductors insulated from earth. The static electricity is converted through a spark gap into dynamic energy of a high number of oscillations and may in such form be coupled as a source of energy b y means of a suitable method f connecting, various precautions being observed and with special regulations. The wires leading from the collector balloons have hitherto been connected through an annular conductor without this endless connection, which can be regarded as an endless induction coil, being able to exert any action on the whole conductor system.

It has now been found that if the network conductor connecting the aerial collector balloons with one another is not made as a simple annular conductor, but preferably short circuited in the form of coils over a condenser battery or spark gap or through thermionic tubes or valves or audions, then the total collecting network exhibits quite new properties. The collection of atmospheric electricity is thereby not only increased but an alternating field may be easily produced in the collector network. Further, the atmospheric electrical forces showing themselves in the higher regions may also be directly obtained by induction. In Figures 26 and 28 a form of construction is shown on the basis of which the further foundations of the method will be more particularly explained.

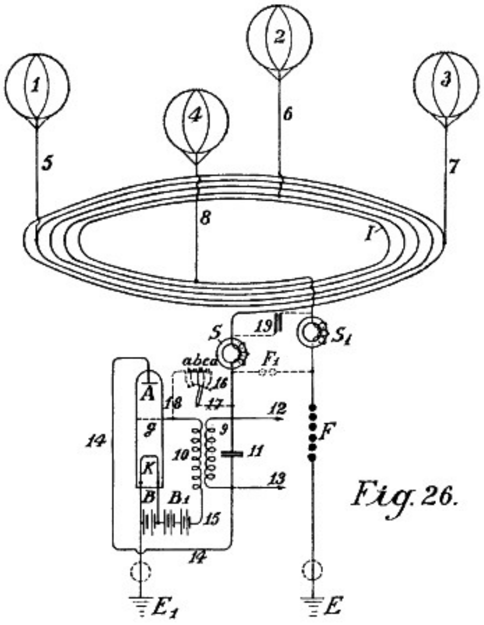


Fig. 26.

In Figure 26, 1, 2, 3, 4 are metal collector balloons, 5, 6, 7, 8 their metallic aerial conductors and I the actual collector network. This consists of five coils and is mounted on high voltage insulators in the air, in high voltage masts (or with a suitable construction of cable embedded in the earth). One coil has a diameter of 1 or 100 km or more. S and S^1 are two protective electromagnets, F the second safety section against excess voltage, E its earth conductor and E1 the earth conductor of the working section. When an absorption of static atmospheric electricity is effected through the four balloon collectors, the current in order to reach the earth connection E1 must flow spirally through the collector network over the electromagnet S, primary induction coil 9, conductor 14, anode A of the audion tube, incandescent cathode K, as the way over the electromagnet and safety spark gap F offers considerably greater resistance. Owing to the fact that the accumulated current flows in one direction, an electromagnetic alternating field is produced in the interior of the collector network coil, whereby the whole free electrons are directed more or less into the interior of the coil. An increased ionization of the atmosphere is thereby produced. In consequence of this the points mounted on the collector balloon show a considerably reduced resistance and therefore increased static charges between the points on the balloon and the surrounding atmosphere are produced. The result of this is a considerably increased collector effect.

A second effect which could not be obtained otherwise is obtained by the electromagnetic alternating field which running parallel to the earth surface, acts more or less with a diminishing or increasing effect on the earth magnetic field, whereby in the case of fluctuations in the current a return induction current of reversed sign is always produced in the collector coil by earth magnetism. Now if, however, a constantly pulsating continuous alternating field is produced as stated in the above collector network I, an alternating current of the same periodicity is produced also in the collecting network coil. As the same alternating field is further transmitted to the aerial balloon, the resistance to its points is thereby considerably reduced, whilst the collector action is considerably increased. A further advantage is that positive electrons which collect on the metal surfaces during the conversion into dynamic current produce a so-called drop of potential of the collector area. As an alternating field is present, the negative ions surrounding the collectors surfaces, when discharge of the collector surfaces takes place produce by the law of induction, an induction of reversed sign on the collector surface and so forth (that is to say again a positive charge). In addition to the advantages hereinbefore set forth, the construction of connecting conductors in coil form when of sufficiently large diameter, allows of a utilization of energy arising in higher regions also in the simplest way. As is well known electric discharges frequently take place at very great elevations which may be observed as St Elmo’s fire or northern lights. These energy quantities have no been available to be utilized up to now. By this invention all these kinds of energy, as they are of an electromagnetic nature and the direction of axis of the collector coils stands at right angles to the earth’s surface, can be more or less absorbed in the same way as a receiver in wireless telegraphy absorbs waves coming from a far distance. With a large diameter of the spiral it is possible to connect large surfaces and thereby to take up also large quantities of energy.

It is well known that large wireless stations in the summer months, and also in the tropics are very frequently unable to receive the signals in consequence of interruptions which are caused by atmospheric electricity, and this takes place with vertical coils of only 40 to 100 meters diameter. If on the contrary horizontal coils of 1 to 100 km diameter be employed very strong currents may be obtained through discharges which are constantly taking place in the atmosphere. Particularly in the tropics or still better in the polar regions where the northern lights are constantly present, large quantities of energy may probably be obtained in this way. A coil with several windings should act the best. In similar manner any alteration of the earth magnetism should act inductively on such a coil.

It is not at all unlikely that earthquakes and spots on the sun will also produce an induction in such collector coils of sufficient size. In similar manner this collector conductor will react on earth current more particularly when they are near the surface of the earth or even embedded in the earth. By combining the previous kind of current collectors so far as they are adapted for the improved system with the improved possibilities of obtaining current the quantities of free natural electricity which are to be obtained in the form of electricity are considerably increased.

In order to produce in the improved collector coil uniform current oscillations of an undamped nature so-called audion high vacuum or thermionic tubes of suitable connection are employed instead of the previously known spark gaps (Figure 26, Nos. 9-18). The main aerial current flows through electromagnet S (which in the case of a high number of alternations is not connected here but in the earth conductor E^1) and may be conveyed over the primary coils in the induction winding through wire 14 to the anode A of the high vacuum grid tube. Parallel with the induction resistance 9 a regulating capacity of suitable size, such as condenser 11 is inserted. In the lower part of the vacuum grid tube is arranged the incandescent filament or the cathode K which is fed through a battery B. From the battery B two branches run, one to the earth conductor E^1 and the other through battery B^1 and secondary coil 10 to the grid above *g* in the vacuum tube. By the method of connections shown in dotted lines, a desired voltage at the grid electrode *g* may also be produced through the wire 17 which is branched off from the main current conductor through switches 16 and some small condensers (*a, b, c, d*) connected in series, and conductor 18, without the battery B^1 being required.

The action of the entire system is somewhat as follows: --

On the connecting conductor of the aerial collector network being short circuited to earth, the condenser pole 11 is charged and slightly damped oscillations are formed in the short circuited existing oscillation circuit formed of the condenser 11 and self inductance 9. In consequence of the coupling through coil 10, fluctuations of voltage take place in the grid circuit 15 with the same frequency, which, fluctuations in turn influence the strength of the electrode current passing through the high vacuum amplifying tube and thus produce current fluctuations of the same frequency in the anode circuit. A permanent supply of energy to the oscillation circuits 9 and 10 consequently takes place, until a condition of balance is set up, in which the consumed oscillation energy is equal to that absorbed. Thereby constant undamped oscillations are now produced in the oscillation circuits 9-11.

For regular working of such oscillation producers high vacuum strengthening tubes are necessary and it is also necessary that the grid and anode voltages shall have a phase difference of 180° so that if the grid is negatively charged, then the anode is positively charged and vice versa. This necessary difference of phase may be obtained by most varied connections, for example, by placing the oscillation circuit in the grid circuit or by separating the oscillation circuit and inductive coupling from the anodes and the grid circuit and so forth.

A second important factor in this way of converting static atmospheric electricity into undamped oscillations is that care must be taken hat the grid and anode voltages have a certain relation to one another; the latter may be obtained by altering the coupling and a suitable selection of the self-induction in the grid circuit, or as shown by dotted lines 16, 17, 18 by means of a larger or smaller number of condensers of suitable size connected in series; in this case the battery B^1 may be omitted. With a suitable selection of the grid potential a glow discharge takes place between the grid *g* and the anode A, and accordingly at the grid there is a cathode drop and a dark space is formed. The size of this cathode drop is influenced by the ions which are emitted in the lower space in consequence of shock ionization of the incandescent cathodes K and pass through the grid in the upper space. On the other hand the number of ions passing through the grid is dependent on the voltage between the grid and the cathode. Thus is the grid voltage undergoes periodic fluctuations (as in the present case) the amount of the cathode drop at the grid fluctuates and consequently the internal resistance of the tube correspondingly fluctuates, so that when a back coupling of the feed circuit with the grid circuit takes place, the necessary means are afforded for producing undamped oscillations and of taking current, according to requirements from the collecting conductor.

The frequency of the undamped oscillations produced is with a suitably loose coupling equal to the self-frequency of the oscillation circuits 9 and 10. By a suitable selection of the self induction of the coil 9 and capacity 11 it is possible to extend from frequencies which produce electromagnetic oscillation of only a few meters wavelength down to the lowest practical alternating current frequency. For large installations a suitable number of frequency-producing tubes of the well-known high vacuum transmission tubes of 0.5 to 2 kw in size may be connected in parallel so that in this respect no difficulty exists.

The use of such tubes for producing undamped oscillations, and also the construction and method of inserting such transmission tubes in an accumulator or dynamo circuit is known and also that such oscillation producing tubes only work well at voltages of 1000 up to 4000 volts, so that on the contrary their use at lower voltages is considerably more difficult. By the use of high voltage static electricity this method of producing undamped oscillations as compared with that through spark gaps must be regarded as an ideal solution particularly for small installations of outputs of from 1 to 100 kw.

By the application of safety spark gaps, with interpolation of electromagnets, not only is short-circuiting avoided but also the taking up of current is regulated. Oscillation producers inserted in the above way form a constantly acting electromagnetic alternating field in the collector coil, whereby as already stated, a considerable accumulating effect takes place. The withdrawal wire or working wire is connected at 12 and 13, but current may be taken by means of a secondary coil which is firmly or movable mounted in any suitable way inside the large collector coil, i.e., in its electromagnetic alternating field, so long as the direction of its axis runs parallel with that of the main current collecting coil.

In producing undamped oscillations of a high frequency (50,000 per second or more) in the oscillation circuits 9 and 11, electromagnets S and S^1 must be inserted if the high frequency oscillations are not to penetrate the collector oil, between the oscillation producers and the collector coil. In all other cases they are connected shortly before the earthing (as in Figures 27 and 28).

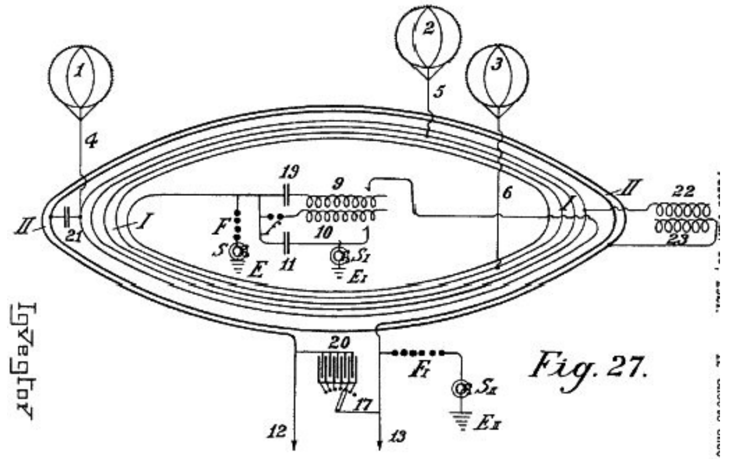

Fig. 27.

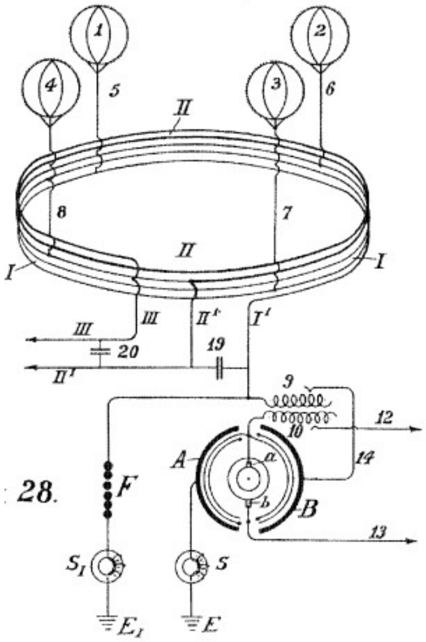
In Figure 27 a second method of construction of the connecting conductor of the balloon aerials is illustrated in the form of a coil. The main difference consists in that in addition to the connecting conductor I another annular conductor II is inserted parallel to the former on the high voltage masts in the air (or embedded as a cable in the earth) but both in te form of a coil. The connecting wire of the balloon aerials is indicated as a primary conductor and also as a current producing network; the other is the consumption network and is not in unipolar connection with the current producing network.

In Figure 27 the current producing network I is shown with three balloon collectors 1, 2, 3 and aerial conductors 4, 5, 6; it is short-circuited through condenser 19 and inductance 9. The oscillation forming circuit consists in this diagram of spark gap f, inductance 10, and condenser 11; the earth wire E, is connected to earth over electromagnet S^1. F s the safety spark gap which is also connected to earth through a second electromagnet S at E. On connecting up the condenser circuit 11 this is charged over the spark gap f whereby an oscillatory discharge is formed. This discharging current acts through inductance 10 on the inductively coupled secondary 9, whereby in the producing network a modification of the potential of the condenser 19 is produced. The consequence of this is that oscillations arise in the coil shaped producer network. These oscillations induce a current in the secondary circuit II, which has a smaller number of windings and a less resistance, the voltage of which, according to the proportion of the number of windings and of the ohmic resistance, is considerably lower whilst the current strength is greater.

In order to convert the current thus obtained into current of an undamped character, and to tune its wavelengths, a sufficiently large regulatable capacity 20 in inserted between the ends 12 and 13 of the secondary conductor II. Here also current may be taken without an earthy conductor, but it is advisable to insert a safety spark gap E1 and to connect this with the earth over an electromagnet S2.

The producer network may be connected with the working network II over an inductionless condenser 21 or over an induction condenser 22, 23. In this case the secondary conductor is unipolarly connected with the energy conductor.



28.

In Figure 28 the connecting conductor between the separate accumulator balloons is carried out according to the autotransformer principle. The collecting coil connects four aerial balloons 1, 2, 3, 4, the windings of which are not made side by side but one above the other. In Figure 28 the collector coil I is shown with a thin line, the metallically connected prolongation coils II with a thick line. Between the ends I^1 and II^1 of the energy network I a regulating capacity 19 is inserted. The wire I^1 is connected with the output wire and with the spark gap F.

As transformer of the atmospheric electricity an arrangement is employed which consists in using rotary pairs of condensers in which the one stator surface B is connected with the main current, whilst the other A is connected with the earth pole. Between these pairs of short-circuited condensers are caused to rotate from which the converted current can be taken by means of two collector rings and brushes, in the form of an alternating current, the frequency of which is dependent on the number of balloons and the revolutions of the rotor. As the alternating current formed in the rotor can act, in this improved method of connection described in this invention, through coils 1 on the inductance 9, an increase or diminution of the feed current in I can be obtained according to the direction of the current by back induction. Current oscillations of uniform rhythm thereby result in the coil shaped windings of the produce network.

As the ends of this conductor are short-circuited through the regulatable condenser 19 these rhythms produce short-circuited undamped oscillations in the energy conductor, the periodicity and wave lengths of which oscillations can be adjusted according to desire by altering the capacity 19 to a given wavelength and therewith also to a given frequency. These currents may also be employed in this form directly as working current through the conductors II^1 and III. By inserting the condenser 20 a connection between these conductors may also be made, whereby harmonic oscillations of desired wavelengths are formed. By this means quite new effects as regards current distribution are obtained. The withdrawal of current can even take place without direct wire connection if, at a suitable point in the interior of the producing network (quite immaterially whether this has a diameter of 1 or 100 km) a coil tuned to these wavelengths and of the desired capacity is firmly or movably mounted in the aerial conductor in such a way that is axial direction is in parallel with that of the collector coil. In this case a current is induced in the producing network, the size of which is dependent on the total capacity and resistance and also on the periodicity employed. A possibility is thereby afforded in future, of taking energy from the producer network by wireless means. As thereby in addition to atmospheric electricity also magnetic earth currents and energy from the higher atmosphere (at leas partially may be simultaneously obtained, this last system for collecting the atmospheric energy is of particular importance for the future.

Of course everywhere instead of spark gaps grid vacuum tubes may be employed as producers for undamped oscillations. The separate coils of the producer network with large diameters may be connected with one another through separate conductors all in parallel or all in series or in groups in series. By regulating the number of oscillations and also the extent of the voltage more or less large collector coils of this kind may be employed. The coils may also be divided spirally over the entire section. The coils may be carried out in angular form or also in triangular, quadrangular, hexagonal or octagonal form.

Of course wires may be carried from a suitable place to the center or also laterally which serve the current waves as guides. This is necessary when the currents have to be conducted over mountains and valley and so forth. In all these cases the current must be converted into a current of suitable periodicity.

As already hereinbefore mentioned separate collecting balloons may be directly metallically interconnected at equidistant stations distributed over the entire country or may be connected by interpolation of suitable condenser batteries by means of high voltage conductors. The static electricity is converted through a spark gap into dynamic energy of a high number of oscillations, and could then in such forms, wit a suitable arrangement of the connections, observing various measures of protection, be employed as source of energy after separate or special regulation.

According to this invention in order to increase the collecting effect of the balloon in the aerial collector conductor or in the earth wire, radiating collectors are employed. These consist either of incandescent metal or oxide electrodes in the form of vacuum grid tubes, or electric arcs (mercury and the like electrodes), Nernst lamps, or finally flames of various kinds may be simply connected with the respective conductor.

It is well known that energy can be drawn of from a cathode consisting of an incandescent body opposite an anode charged with positive electricity (vacuum grid tube). Hitherto however, a cathode was always first directly placed opposite an anode, and secondly the system always consisted of a closed circuit.

Now if we dispense with the ordinary ideas in forming light or flame arcs in which a cathode must always stand directly opposite an anode, charged to a high potential or another body freely floating in the air, or regard the incandescent cathode only as a source of unipolar discharge (which represent group and point discharges in electrostatic machines similar to unipolar discharges), it may be ascertained that incandescent cathodes and less perfectly all incandescent radiators, flames and the like admit of relatively large current densities and allow large quantities of electric energy to radiate into the open space in the form of electron streams as transmitters.

The object of this invention is as described below, if such incandescent oxide electrodes or other incandescent radiators or flames are not freely suspended in space but connected metallically with the earth so that they can be charged with negative terrestrial electricity, these radiators possess the property of absorbing the free positive electrical charges contained in the air space surrounding them (that is to say of collecting them and conducting them to earth). They can therefore serve as collectors and have, in comparison to the action of the spikes, or points, a very large radius of action R; the effective capacity of these collectors is much greater than the geometrical capacity (R_{o-}) calculated in an electrostatic sense.

Now as our earth is surrounded as is well known with an electrostatic field and the difference of potential

$$\frac{\delta V}{\delta h}$$

of the earth field according to the latest investigations, is in summer about 60 to 100 volts and in winter 300 to 500 volts per meter of difference in height (δh), a simple calculation gives the result that when such a radiation collector or flame collector is arranged for example on the ground, and a second one is mounted vertically over it at a distance of 2000 meters and both are connected by a conducting cable, there is a difference in potential in summer of about 2,000,000 volts and in winter even of 6,000,000 volts and more.

According to Stefan Boltzmann's law of radiation, the quantity of energy which an incandescent surface (temperature T) of 1 sq cm radiates in a unit of time into the open air (temperature T_o) is expressed by the following formula:

$S = \delta \, (T^4 - T^4_o)$ watt./sq cm.

And the universal radiation constant δ is according to the latest researches of Ferry (*Annales de Chimie et de Physique*, 17: 267 [1909]) equal to 6.30 x 10^{-12} watt/sq cm.

Now if an in incandescent surface of 1 sq cm shows, as compared with the surrounding space a periodic fall of potential δV it radiates (independent of the current direction, that is to say of the sign) in accordance with the above formula, for example at a temperature of 3725° C an energy of 1.6 kw/sq cm/second. As for the radiation the same value can be calculated for the collection of energy, but reversed. Now, as carbon electrodes at the temperature of the electric arc support on the current basis a current density up to from 60 to 65 amperes per sq cm no difficulties will result in this direction in employing radiating collectors as accumulators.

If the earth be regarded as a cosmically insulated condenser in the sense of geometrical electrostatics *x* there results from the geometric (compare Edwald Rasch: *Das Elektrische Bogenlicht* [The Electric Arc Light], page 169) capacity of the earth according to Chwolson:

For negative charging 1.3 x 10^6 Coulomb

For negative potential V = 10 x 10^8 volts.

From this there results however, EJT = 24.7 x 10^{24} watt/sec. Now if it is desired to make a theoretic short circuit through an earthed flame collector this would represent an electric total work of about 79,500 x 10^{10} kilowatt years. As the earth must be regarded as a rotating mechanism which thermodynamically, electromagnetically and also kinematically coupled with the sun and star system by cosmic radiations and gravitation a diminution of the electric energy of the earth field is not to be feared. The energies which the incandescent collectors would withdraw from the earth field can only case by the withdrawal of motor work a lowering of the earth temperature (temperature $T_E = 300$) and reduce this to that of the world space (T = O) by using the entire energy. This is however not the case as the earth does not represent a cosmically entirely insulated system. On the contrary there is conveyed to the same according to the recent value corrected by Perry for the solar constants through the radiation from the sun an energy of 18,500 x 10^{10} kw. Accordingly, any lowering of the earth temperature (T_E) without a simultaneous lowering of the sun's temperature (T_s) would contradict Stefan Boltzmann's law of radiation.

$S = \delta \, (s^4 - T^4)$.

From this it must be concluded that if the earth temperature (T_E) sinks the total radiation S absorbed by the earth increases, and further also that the secular speed of cooling of the earth is directly dependent on that of the sun and the other radiators cosmically coupled with the sun and is connected most closely with these.

The incandescent radiation collectors may, according to this invention, be employed for collecting atmospheric electricity if they (1) are charged with the negative earth electricity (that is to say when they are directly connected by means of a metallic conductor with the earth) and (2) if large capacities (metal surfaces) charged with electricity are mounted opposite them as positive poles in the air. This is regarded as the main feature of the present invention as without these inventive ideas it would not be possible to collect with an incandescent collector, sufficiently large quantities of the electrical charges contained in the atmosphere as the technology requires; the radius of action of the flame collectors would also be too small, especially if it be considered that the very small surface density (energy density) (δ about = 2 x 7 . 10^9 St. E. per sq cm) does not allow of large quantities of charge being absorbed from the atmosphere.

x) Calculated according to Poisson's calculation:

$\Delta V = -4\pi\delta$; as here the alteration of the potential or potential gradients only takes place in the direction o the normal, this calculation assumes the simple form

$$\delta = \frac{1}{4\pi} \times \frac{\delta^2 V}{\delta n^2}$$

It has indeed already been proposed to employ flame collectors for collecting atmospheric electricity and it is known that their collecting effect is substantially greater opposite the points. It is however, not known that the quantities of current which could hitherto be obtained are too small for technical purposes. According to my experiments the reason for this is to be found in the too small capacities of the collector conductor poles. If such flame or radiating collectors have no or only small positive surfaces, their radius of action for large technical purposes is too small. If the incandescent collectors be constantly kept in movement in the air they may collect more according to the speed of the movement, but this again is not capable of being carried out in practice.

By this invention the collector effect is considerably increased by a body charged with a positive potential and of the best possible capacity being also held floating (without direct earth connection) opposite such an incandescent collector which is held floating in the air at a desired height. If for example, a collecting balloon of sheet metal or of metalized balloon fabric be caused to mount to 300 up to 3000 meters in the air and as positive pole it is brought opposite such a radiating collector connected by a conductor to the earth, quite different results are obtained.

The metallic balloon shell (with a large surface) is charged to a high potential by the atmospheric electricity. This potential is greater the higher the collecting balloon is above the incandescent collector. The positive electricity acts concentratedly on the anode floating in the air as it is attracted through the radiation shock ionization, proceeding from the incandescent cathode. The consequence of this is that the radius of action of the incandescent cathode collector is considerably increased and thereby also the collection effect of the collecting balloon surface. Further the large capacity of the anode floating in the air plays therefore an important part because it allows of the taking o large charges, and thereby a more uniform current is obtained even when there is a large consumption: this cannot be the case with small surfaces.

In the present case the metallic collecting balloon is a positive anode floating in the air and the end of the earth conductor of this balloon serves as positive pole surface opposite the surface of the radiating incandescent cathode, which in turn is charged with negative earth electricity being conductively connected to earth.

The process may be carried out by two such contacts (negative incandescent cathode and anode end of a capacity floating in the air) a condenser and an inductive resistance being switched on in parallel, whereby simultaneously undamped oscillations may be formed.

In very large installations it is advisable to connect two such radiating collectors in series. Thus an arc light incandescent cathode may be placed below on the open ground and an incandescent cathode which is heated by special electromagnetic currents be located high in the air. Of course for this the special vacuum Liebig tubes wit or without grids may also be employed. An ordinary arc lamp with oxide electrodes may be introduced on the ground and the positive pole is not directly connected with the collecting balloon, but through the upper incandescent cathode or over a condenser. The method of connecting the incandescent cathode floating in the air may be seen in Figures 29-33.

B is the air balloon, K a Cardan ring (connection with the hawser), C the balloon, L a good connecting cable, P a positive pole, N negative incandescent cathode, and E earth conductor.

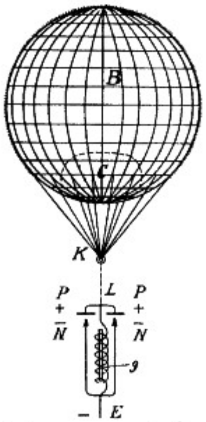


Fig. 29.

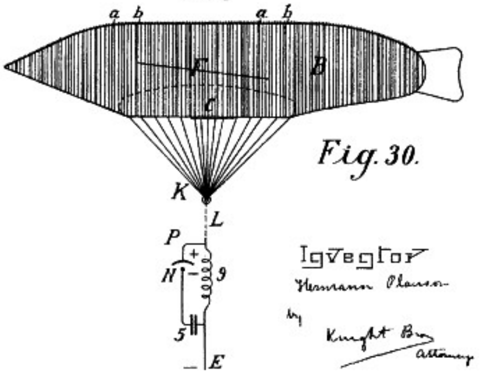

Fig. 30.

Figure 29 represents the simplest form of construction. If electric oscillations are produced below on the ground by means of a carbon arc lamp or in other suitable way a considerably greater electric resistance is opposed to that in the direct way by inserting an electrical inductive resistance 9. Consequently between P and N, a voltage is formed, and as, over N and P only an inductionless ohmic resistance is present, a spark will spring over so long as the separate induction co-efficients and the like are correctly calculated. The consequence of this is that the oxide electrode (carbon or the like) is rendered incandescent and then shows as incandescent cathode an increased collecting effect. The positive poles must be substantially larger than the negative in order that they may not also become incandescent. As they are further connected with the large balloon area which has a large capacity and is charged at high voltage, an incandescent body which is held floating in the air and a positive pole which can collect large capacities is thereby obtained in the simplest way. The incandescent cathode is first caused to become incandescent by means of separate energy produced on the earth, and then maintained by the energy collected from the atmosphere.

Figure 30 only shows the difference that instead of a round balloon a cigar-shaped one (of metal or metalized fabric) may be employed and also a condenser 5 is inserted between the incandescent cathode and the earth conductor so that a short circuited oscillation circuit over P.N. 5 and 9 is obtained. This has the advantage that quite small quantities of electricity cause the cathode to become incandescent and much larger cathode bodies may be rendered incandescent.

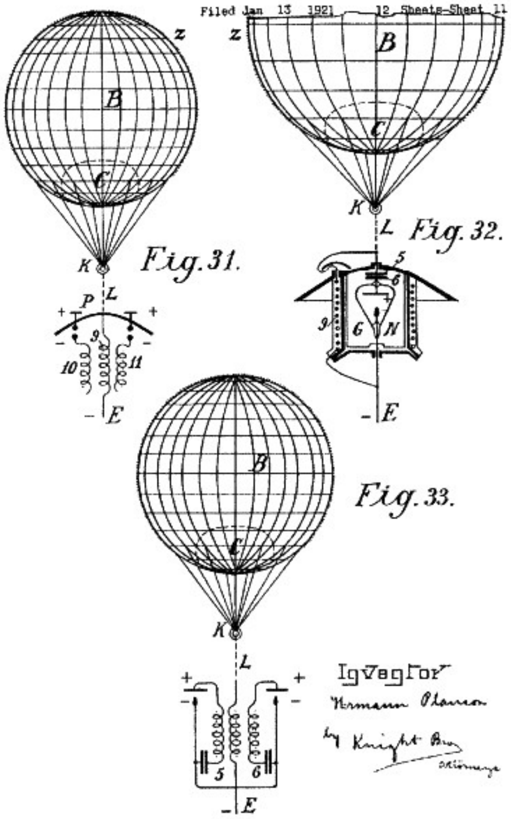

Fig. 31.

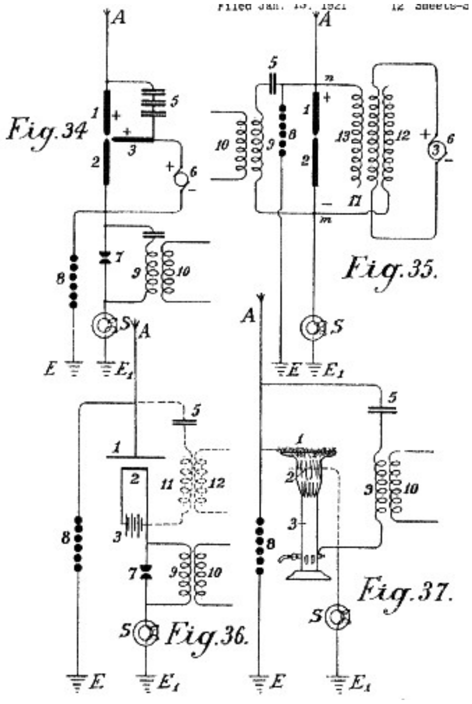
Fig. 32.

Fig. 33.

In this form of construction both the incandescent cathode and also the positive electrode may be enclosed in a vacuum chamber as may be seen in Figure 32. A cable L is carried well insulated through the cover of a vessel and ends in a condenser disc 5. The cover is arched in order to keep off the rain. The vessel is entirely or partially made of magnetic metal and well-insulated inside and outside. Opposite the disc 5 another disc 6 and on this again a positive pile of the vacuum tube g with the incandescent cathode (oxide electrode) N is arranged. The negative electrode is on the one hand connected with the earth conductor E, and on the other hand with the inductive resistance 9 which is also connected with the cable L with the positive pole and wound round the vessel in coils. The action is exactly the same as that in Figure 29 only instead of an open incandescent cathode one enclosed in vacuo is employed. As in such collectors only small bodies can be brought to incandescence in large installations a plurality of such vacuum tubes must be inserted in proximity to one another. According to the previous constructions Figures 31 and 33 are quite self evident without further explanations.



Figures 34-37 represent further diagrams of connections over radiating and flame collectors, and in fact, how they are to be arranged on the ground.

Figure 34 shows an arc light collector with oxide electrodes for direct current and its connection; Figure 35 a similar one for alternating current, Figure 36 an incandescent collector with a Nernst lamp and Figure 37 a similar one with a gas flame.

The positive pole 1 of the radiating collectors is always directly connected to the aerial collecting conductor A. In Figure 34 this is further connected over the condenser battery 5 with a second positive electrode 3. The direct current dynamo *b* produces current which flows over between the electrodes 3 and 2 as an arc light. On the formation of an arc the negative incandescent electrode 2 absorbs electricity from the positive poles standing opposite it and highly charged with atmospheric electricity and conveys the same to the working circuit. The spark gap 7, inductive resistance 9 and induction coil 10 are like the ones previously described. The protective electromagnet S guards the installation against earth circuiting, the safety spark gap 8 from excess voltage or overcharging.

In Figure 35 the connection is so far altered that the alternating current dynamo feeds the exciting coil 11 of the induction condenser. 12 is its negative and 13 its positive pole; if the coil 3 on the magnet core of the dynamo is correctly calculated and the periodicity of the alternating current is sufficiently high an arc light can be formed between the two poles 1 and 2. As the cathode 2 is connected with the negatively charged earth, and therefore always acts as a negative pole, a form of rectification of the alternating current produced by the dynamo 3 is obtained, the second half of the period is always suppressed. The working circuit may be carried out in the same way as in Figure 34; the working gap 7 may however be dispensed with, and instead thereof between the points m and n a condenser 5 and an induction resistance 9 may be inserted from which the current is taken inductively.

Figure 36 represents a form of construction similar to Figure 34 only that here instead of an arc lamp a Nernst incandescent body is employed. The Nernst lamp is fed through the battery 3. The working section is connected with the negative pole, the safety spark gap with the + poles. The working spark gap 7 may also be dispensed with and the current for it taken at 12 over the oscillation circuit 5, 11 (shown in dotted lines).

Flame collectors (Figure 37) may also be employed according to this invention. The wire network 1 is connected with the aerial collector conductor A and the burner with the earth. At the upper end of the latter, long points are provided which project into the flame. The positive electrode is connected with the negative over a condenser 5 and the induction coil 9 with the earth.

The novelty in this invention is firstly, the use of incandescent cathodes opposite positive poles which are connected with large metallic capacities as automatic collecting surfaces, (2) the connection of the incandescent cathodes with the earth whereby, in addition to the electricity conveyed to them from the battery or machine which causes the incandescing, also the negative charge of the earth potential is conveyed, and (3) the connection of the positive and negative poles of the radiating collectors over a condenser circuit alone or with the introduction of a suitable inductive resistance, whereby simultaneously an oscillatory oscillation circuit may be obtained. The collecting effect is by these methods quite considerably increased.

I declare that what I claim is: --- [Claims not included here]

Improvements in Electric Motors

Hermann Plauson // Otto Traun’s Forchungs-Laboratorium GmbH

This invention relates to that type of motor in which rotation is produced by means of the attraction and repulsion of surfaces carrying charges of electricity.

According to this invention a stator and rotor are formed of condensor surfaces and charges of electricity thereon imposed in the form of alternating currents of high frequency.

The invention is more particularly described with reference to the accompanying drawing in which: ---

Figure 1 shows a simple form of motor and feed.

The inner plates of the condenser 5 and 6 are charged from a spark gap 7, 8 connected to a source of energy of sufficiently high pressure (alternating or direct current), until the potential has risen so far that a spark springs over.

The spark gap 7, 8 forms with the condenser 5 and self-inductance 9 and condenser 6 a closed oscillatory circuit and alternating currents of high frequency will be produced in this circuit. The high frequency current produced in the primary circuit 9 excite by induction in the secondary circuit 10 currents of the same periodicity.

The improved type of motor is fed by the discharges produced by the induction in the secondary circuit.

Hitherto only Tesla's motor system (shown diagrammatically in Figure 1, 16 and 17) was known for this purpose. The above-mentioned diagram is only shown for illustrating the fundamental principle. It has however no practical interest for carrying out large machines by reason of the impossibility of the regulation and the low efficiency.

Now according to this process, all these defects are overcome by the construction of a machine which is applicable for high frequency currents and of a more or less undamped nature. The difference between the principle of construction of these motors as compared with those hitherto customary consists in that the motor is not based on the principle of magnetic induction only (as have been all motors hitherto and also Tesla's motors).

It has been fund that the machine constructed according to Figure 1 cannot only be fed directly with static electricity but if it is connected to a source of high frequency current it will operate.

The applicants call this new type of motors 'condenser motors' to differentiate them from hitherto existing types.

The simplest form of construction of such condenser motors is shown in Figure 1, and this motor may be fed with high frequency alternating currents.

At a given moment positive electricity is charged by means of the lead 14 to the stator surface 1 and to the brush 3x (Figure 1). The brush 3x is connected with the rotor condenser surface 3, so that both the stator surface 1 and also the rotor surface 3 is charged with positive electricity. The stator surface 1 and the rotor surface 3 being both charged with positive electricity and the second rotor surfaces 4 and 4a by brushes 4x with negative electricity, such motors can then be started by providing intermediate stator surfaces 11, 12, the earth connection 13 of one of which is broken by a switch (not shown) according to the direction of rotation desires, or alternatively the motor may be started by a separate source of alternating current in a manner similar to the starting of synchronous motors of known construction. After a half revolution of the rotor the brush 3x comes in contact with the second collector surface 4 so that now this surface is connected by the brush 3x with the stator surface 1 and the brush 4x with the collector surface 3. Consequently with a reverse direction of current through the second half of the oscillation period all the hereinbefore mentioned effects take place in the reverse direction which, however, produces no alteration in the direction of rotation because the dead points between two directions of oscillation are overcome by inertia.

Although this motor is easy to start it can only be employed for small experimental and measuring purposes because the stator and rotor surfaces are made of solid metal and are heated by Foucalt (eddy) currents. In spite of its simplicity and its unsuitability for use in practice it must however be regarded as a basic type for technical calculations.

The condenser motor shown in Figure 2 differs from Figure 1 by the rotor surfaces consisting of six condenser surfaces connected one behind the other in series and they are connected with three collector surfaces, so that at any one moment only two adjacent collector surfaces come under the two brushes (3 and 4). In its other actions it corresponds to Figure 1. The leads 14 and 15 may be connected either to the ends of the secondary coil 10 or directly with the source of energy. The outer thicker line indicates the stator surfaces 1 and 2 (that is to say the unmoving part of the motor), 11 and 12 shown by thick dotted lines means earthed additional poles of the stator, 8, 9, and 10 are the outer parts of the rotor condenser surfaces which in turn are connected with the collector surfaces 8, 9, and 10. 5, 6, and 7 are the inner parts of the condenser surfaces of the rotor and 3 and 4 are brushes.

Hitherto stator and rotor surfaces of compact metal have been spoken of. These however become highly heated with eddy currents and hardly yield 10-15% of useful effect. In examining into such small useful effects it was found that certain forms of metal sections in the stator and condenser surfaces highly increase these. It was then further found that if slots or notches be cut in the metal surfaces of the stator and rotor in the form of a spiral, not only was a higher useful effect possible, but also an easier starting and even a regulation could be obtained.

Experiments have shown that by such a form of construction it is possible to build a very useful motor for high frequency alternating currents more particularly those of an undamped nature.

If for example the system of construction of a stator shown in Figure 1, but four polar, be taken and the system of rotor construction shown diagrammatically in Figure 5, but with the form of construction of the condensers of the stator as well as of the rotor according to Figure 3, a condenser motor is obtained which works well in either direction for high frequency alternating current. It was also observed that the motors in such forms of construction were found to be more sensitive to resonance effects. Such a motor then works the best if stator and rotor surfaces have equal capacity and self-inductance so that the windings both in the stator and also in the rotor are in resonance.

A motor constructed according to the foregoing kind is already fully technically applicable. But even these motors have a series of faults, more particularly in their building construction. For example, the attachment of the spiral condenser surfaces both of the stator and of the rotor sown in Figure 3 are in practice difficult to carry out. Therefore in practice the condenser and stator surfaces are simply wound of wire or bands in the form shown in Figure 4. Such stator and rotor surfaces may, without further difficulty, be regarded as electromagnetic poles, although they are not made of iron as is the case in electromagnets. Such machines may be spoken of directly as motors for high frequency alternating currents in which the separate pole surfaces consists of wound induction condenser surfaces of which one is sound on the stator and the other on the rotor.

If the coil as shown in Figure 4 be made of well insulated wires the coil can be embedded in insulating material either for the stator or motor surfaces as has already been done in the case of ordinary single and multiphase motors. At the same time the possibility is afforded by increasing the number of turns to produce a greater or smaller alteration of the self induction co-efficients.

In Figure 5 is shown a modified construction of a rotor for a four pole motor consisting of four condenser surfaces 1, 2, 3, 4, of which 1 and 2 are connected though an iductance 9 coupled with the coil 10. Four inner surfaces 5, 6, 7, 8 are provided of which 5 and 6 are directly connected also 7 and 8 similarly connected.

The pairs of like poles are connected by wires 14 and 15 to the source of energy. By a suitable selection of the values of the reactance and capacity in these circuits resonance circuits may be formed.

Having now particularly described and ascertain the nature of our said invention and in what manner the same is to be performed, we declare that what we claim is: --- [Claims not included here]

British Patent # 157,263

Process & Apparatus for Converting Static Atmospheric Electrical Energy into Dynamic Electrical Energy of any Suitable High Periodicity

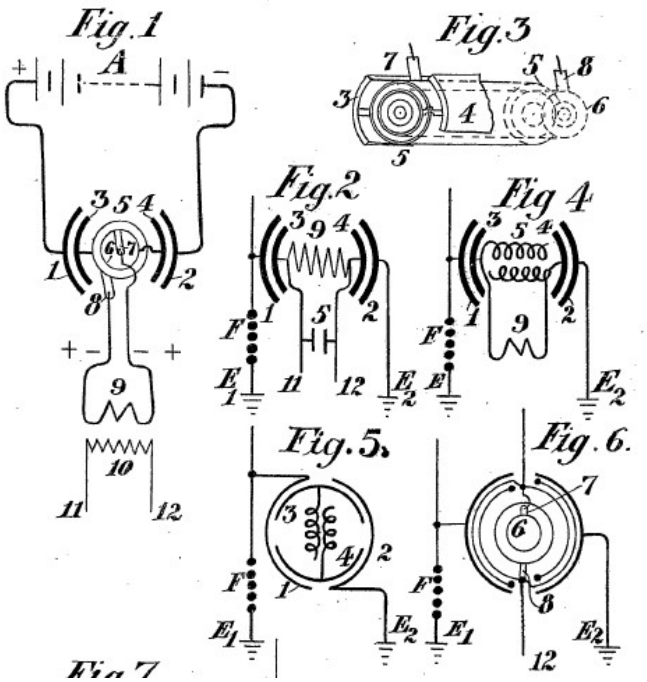
Hermann Plauson // H.O. Traun's Forschungs-Laboratorium GmbH

Static aerial electricity in the form of direct current can be converted by using spark gaps and with the assistance of oscillatory circuits into dynamic electrical wave energy of a high number of alternations of a more or less undamped nature and in such form --- either direct or by means of a special kind of resonance or 'condenser motors' --- ready to be utilized for technical purposes as mechanical energy.

For small installations this system may be very well employed; about 100 horsepower may be stated as practical limit. In constructions of larger aggregate difficulties as regards the spark gaps however increase considerably. Further it is desirable to convert the accumulated currents of from 100 to 1000 periods which may then be used for the ordinary types of alternating current machines instead of into electromagnetic waves of a high number of alternations.

In experimenting with condenser motors the construction of which forms the object of British Patent # 157,262 it was observed that the rotor, if one pole of the stator surface be connected with the aerials collecting aerial electricity and the other pole with the earth, not only could act as a motor, but if vice versa the rotor connection with the stator be interrupted and the rotor caused to rotate by means of another motor, that when the brushes supply an alternating current the periodicity of which is dependent on the number of poles and the revolutions of the rotor. Such an apparatus may therefore be regarded as a transformer of static into dynamic electrical energy.

The invention is more particularly described with reference to the accompanying diagrams in which: ---



In Figure 1A is a strong accumulator battery, 1 and 2 are the outer poles of the transformer, consisting of simple metallic plates or are as shown in Figures 8-11, made of wire coils without an electromagnet being present. Between these poles an armature is revolubly mounted on a shaft, which armature also consists of two similar cylindrically curved plates 3 and 4. These are metallically connected with two collector rings 5 and 6 on which two brushes 7 and 8 freely run which again are short-circuited with one another over a primary coil 9. 10 is the secondary coil with the free ends 11 and 12. If through the accumulator battery the stator plate 1 is charged with positive electricity, it induces a charge of reverse sign on the rotor surface 3 which is connected by the brushes 7 and 8 over the primary coil 9 with the second rotor surface 4. This latter is therefore charged with positive electricity, which in turn induces negative electricity on the stator surface 2/ Up to this moment everything takes place in the same way as if two condensers were connected one behind the other in the current circuit A. If however, by means of mechanical power, this rotor be caused to rotate, the surface conditions are altered. After a quarter revolution the rotor plates are between the stator plates and therefore no condenser surface faces another. By this means however, the capacity of the entire system is reduced to a minimum and a change of current will also result in the main 9. Now if the rotor be turned further through 90 degrees by mechanical energy the rotor plate 3 comes opposite the stator plate 2 and the rotor plate 4 opposite the stator plate 1, so that then the rotor pates are in a field of reverse sign. A fresh charge of current in the reverse direction now runs through the primary coil 9. After a further half revolution the same action is repeated so that after a full revolution the initial condition is again produced. The result of such a revolution is an alternating current the periodicity of which is equal to the number of revolution. In practice of course not two poles but as many poles as possible would be employed because thereby the number of alternations would e considerably increased. The primary alternating current thus obtained induces in the secondary circuit an alternating current the potential of which is dependent on the winding of the coil. Figure 7 shows a multipolar machine.

If the stator surface 1, instead of being connected with the battery be connected with a collecting aerial network and the other stator surface 2 be directly earthed, but the rotor wich is otherwise constructed as hereinbefore, be rotated by a separate motor a much stronger alternating current results which is to be ascribed to the circumstance that a much higher potential can be charged on the pole surfaces of the stator by reason of the higher pressure of the static electricity than where accumulators are employed. By this means the transformer has of course much larger quantities of energy supplied to it.

Figure 2 shows a mode of connections. The stator surface 1 is connected with the aerial antennae which is connected through the safety spark gap F to earth at E1. The stator surface 2 is directly earthed at E2. The inner revoluble rotor surfaces 3 and 4 are interconnected by means of an induction coil which is constructed directly in the motor. The current is taken as in Figure 1 up to collector rings by means of brushes, which are not shown for the sake of clearness, and further conveyed through the conductors 11 and 12. Between these a condenser 5 may be inserted. There is thereby formed a short oscillatory oscillation circuit free from spark gaps, which circuit consists of the induction coil 9 and condenser 5 and is fed by the periodic charging current impulse. By this means the possibility is afforded of obtaining a kind of current which is characterized by longer periods and is undamped and oscillatory. Of course a simple alternating current may be obtained by cutting out the condenser.

Instead of the induction coil the condenser may also b constructed in the rotor. His can be carried out in such a way that its ends serve directly as collector rings for taking current through the brushes. In Figure 3 such a motor is sketched in perspective, 3 and 4 are the rotor surfaces, 5 and 6 are the condenser surfaces constructed to form part of the rotor consisting of two co-axial cylinders fitting one in the other in such a way that free room is left for the brushes 7 on one end of the condenser cylinder 6.

The condenser may be made in the form of a cylindrically wound spiral forming the capacity and reactance as shown in Figure 4. A further type of transformer is shown in Figure 5. The difference consists in the stator and rotor surfaces not only each assuming a quarter of the circuit but almost the half. By this means the space and the effective condenser surface is better utilized. Charge is produced only when the rotor surfaces face the full scope of the stator surfaces.

In addition a condition is obtained in which the stator surfaces are inductively connected by the rotor surfaces. The consequence of this is that an alternating current simultaneously results which is produced without sparking otherwise the connection is as before.

Figure 6 shows the alternation of the rotor surfaces; the rotor here consists of two cylindrical condenser plates arranged concentrically, each divided into two halves and connected so that half the inner cylinder is connected to half the outer. Such a machine shows the more complete transformer action.

Fig.7.

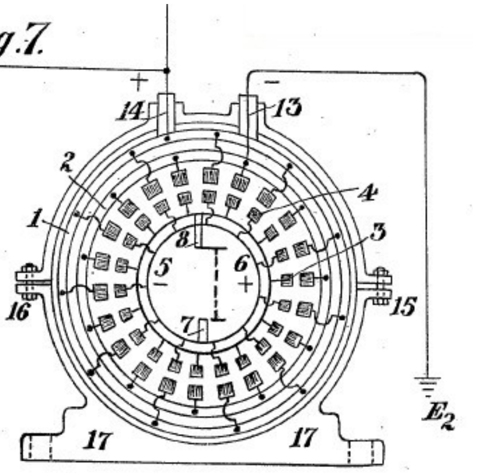


Figure 7 shows a four polar transformer. It consists of a metal casing, the lower half of which is fastened with the foundation plates 17 to the support or foundation. The upper half, the cover, is connected by bolts 15 and 16 firmly with the under part. This upper sleeve or casing is insulated from the under part. Two rings 1 and 2 are cylindrically constructed in the casing. The ring 1 is metallically connected with the collector aerial and the ring 2 with the earth. On both rings an equal number of stator surfaces are mounted side by side but well insulated from one another and thus form an electrostatic field similar to the electromagnetic in many alternating current machines. The rotor consists in similar manner of two rings 5 and 6 on which an equal number of rotor surfaces are fixed so that each stator surface faces a rotor surface. By the brushes 7 and 8 the alternating current formed is removed from the collector. The charge is conveyed by the conductor 14 to and by 13 away. If this rotor be then rotated by means of a motor the positive and negative fields precisely as in the case of magnetizing will alter and thereby an alternating current is formed in the rotor, the periods of which are dependent on the number of the poles and the revolutions per second.

At the commencement it was thought that this apparatus could only be regarded as alternating current converters, but it was soon found that much more energy was necessary to rotate the rotor than might be necessary to overcome the friction. It was then found that the considerable expenditure of energy for rotating the rotor was caused by a conductor being moved through strongly electrostatic fields since the electrostatic lines of force must be cut at right angles and that further in the conductors a stronger current arose than was otherwise to be expected. This apparatus must therefore not only be regarded as a transformer, but also as an energy producer, with the difference that the excitation here is obtained instead of by means of electromagnets, by static fields of high pressure. The entire system may, to some extent, be compared with a dynamo in which the excitation takes place by means of a fixed constant magnet. It was further ascertained that this way of using the atmospheric electricity produced a sort of suction on the collector network, and that thus suitable greater quantities of current could be obtained.

The effects which in this apparatus became evident are extremely interesting and open a prospect of being able to obtain here a great deal more. Merely that these transformer made it possible to transform suitable quantities of atmospheric electricity into alternating current of high or lower frequency (without the use of spark gaps) shows already the extreme utility of these apparatus. Should in future, the construction of larger aggregates be necessary the transformer installation may be constructed in such a way that motors which are fed by a current obtained from an installation with spark gaps produce a certain quantity of energy which may then be employed for producing current according to the last described system.

The results of the examinations made for this may be construed as follows.

(1) If solid electrodes (condenser surfaces, rotor and stator surfaces) are employed they become hot. This effect may be considerably reduced by cutting the electrodes in ribbed form Figure 8, but not entirely removed. This form allows the surface of the condenser plate to be enlarged or increased; the electrodes may be fastened in a simple manner on the under frame by perforation 1, 2, 3, 4, 5.

Fig.8

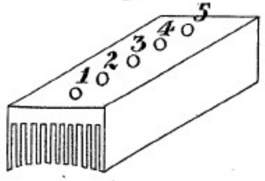

Fig. 9.

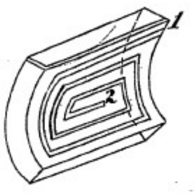

(2) If nicks or notches in spiral form as shown in Figure 9 seen from the side end in Figure 10 in section are employed, not only is the transformer effect greater but the poles yields also more current, but require greater quantities of energy for their movement than a simple commutator action would require.

Fig. 10

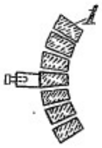

Fig. 11

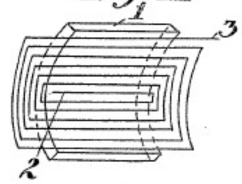

(3) The greatest effect is obtained if the rotor and stator surfaces are wound in flat spiral form of suitably thick wire, and in such a way that the inductive effect combining with the capacity is calculated in suitable proportion and this result is adapted to a suitable periodicity. In practice this is preferably done by the wire bent in spiral form being inserted in a separate vulcanite or hard rubber mass (see Figure 11) so that a smooth pole surface is formed similar to that in phase motors.

Fig.12

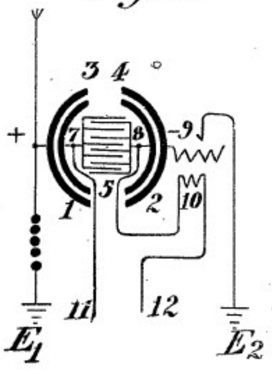

Fig. 13.

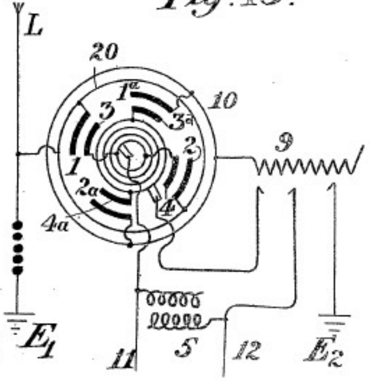

Regular undamped oscillations of a high frequency may however be produced if the converter be carried out in the manner shown in Figure 13. The aerial wire L is metallically connected with the ring 20. To this two pole surfaces 1 and 2 are connected. The inductive earth pole is also connected with a second ring 10 from which again two, poles 1a and 2a are branched off. Of course in similar manner any suitable number of poles may be branched of. In similar manner there are in the rotor two poles fastened to one another (3 and 4 and 3a and 4a) connected with separate collector rings. From these two rings the current is collected by means of two brushes. The induced alternating current is however directly metallically connected with an inductive earth stator conductor over an induction coil 9. Further a combined inductance and capacity 5 is inserted between the two wires 11 and 12 in parallel with the converter. By this means a sparkless oscillatory circuit is obtained which can act on the exciting current in the stator. This produces however, a periodic alteration of the charging quantities according to the oscillation curves of the rotor currents in consequence of which the stator charge also commences with resonance oscillations and if the stator and rotor surfaces are calculated to one another in such a way that they are adapted to form oscillations of waves of similar length the entire converter is caused to oscillate and furnishes undamped oscillations of a high number of alternations, but of periodically changed amplitude, the form of which is dependent on the amplitude of the main alternating current and is caused by the number of the poles and revolutions per second. Thus an alternating current of, for example, 100 periods is formed, the separate periods of which are formed by undamped oscillations of a higher number of alternations. In Figures 14-16 four other diagrams of converters are illustrated, the object of which is not to produce usual alternating current, but oscillations of high frequency.

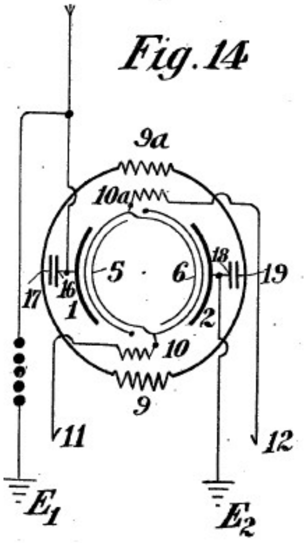

Fig. 14

The main difference of these systems from those previously described is that from the connection of the collecting aerials is made between the stator pole 1 (Figure 14) and one pole 16 of the condenser 17 and the earth connection between a second stator pole 2 and the pole 18 of the condenser 19. The other poles of these condensers 17 and 19 are short circuited through a ring over two inductive primary coils 9 and 9a with one another. The secondary coils form the rotor conductors 10 and 10a. The rotor itself is constructed in the manner shown in Figure 6 of two short-circuited plate condensers which may be wound as shown in Figure 11. In similar manner of course the stator surfaces may also be formed. The collector rings of the rotor with the two brushes for collecting current are here not shown in order to simplify the drawings. By the connection of the two condensers in the exiting circuit of the converter and also by the action of the alternating current produced in the rotor on the stator circuit, with a correct calculation of the capacity and the self-induction co-efficients a maximum action may be obtained. The kind of current produced will be similar to that described for Figure 12.

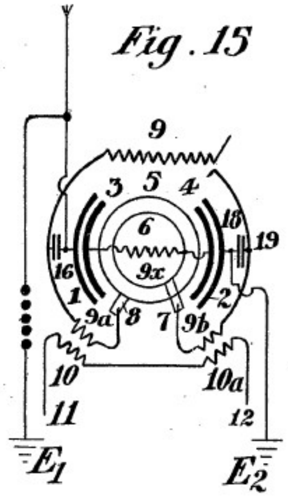

Fig . 15

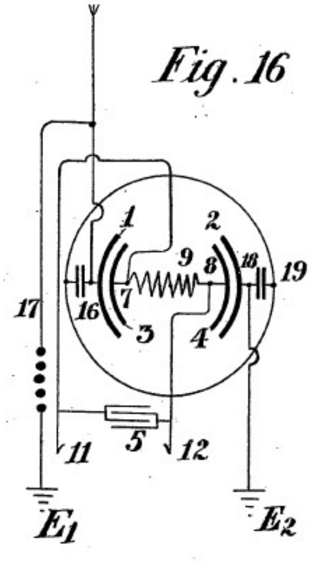
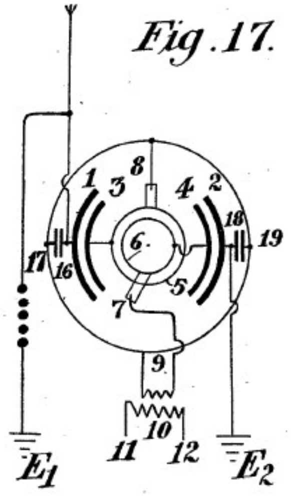
The novelty of the converter illustrated in Figure 15 consists mainly in that the current resulting in the rotor is not directly employed, but only serves a exciter of the primary coils 9a and 9b. The working current is produced in the secondary coils 10 and 10a and further conducted through the conductors 11 and 12. The stator current may be brought by the regulatable inductive resistance 9 to the same resonance as the rotor current.



In Figure 16 a very similar system is shown to Figure 14. The condenser 5 is however connected in parallel with the converter; and by the inductive resistance constructed in the rotor a short circuited oscillatory circuit is formed which gives extraordinarily good results and is simple in construction.

The inductive resistance 9 may also instead of being constructed in the rotor be constructed as primary coil employed outside the rotor and short circuit the oscillatory circuit over the stator surfaces (see Figure 17).



The last six types serve only for producing oscillations of a high number of alternations. If it be desired to obtain ordinary alternating current there complicated constructional arrangements are not required as the types illustrated in Figures 1 to 11 suffice. It is self-evident that these arrangements may be altered in various ways by means of different condenser surfaces in practice.
Having now particularly described and ascertained the nature of our said invention and in what manner the same is to be performed, we declare that what we claim is: --- [Claims not included here]

Bio: I love simplicity, function and precision job!

I am big fan of old radios, and I am fascinating how precision were the radios making. 4 months ago, I was just looking for some interesting schematcs, and I found one! It's about 50 years old, but works perfectly, without any power supply. With the reciever you can listen to your favourite radio on middle waves. You just need some electronic components, long antenna, good ground and HI-Z earphones (or amplifier). To make it you don't need any money! All components I used were recycled! Please, respect the nature!!

Let's make it! :))

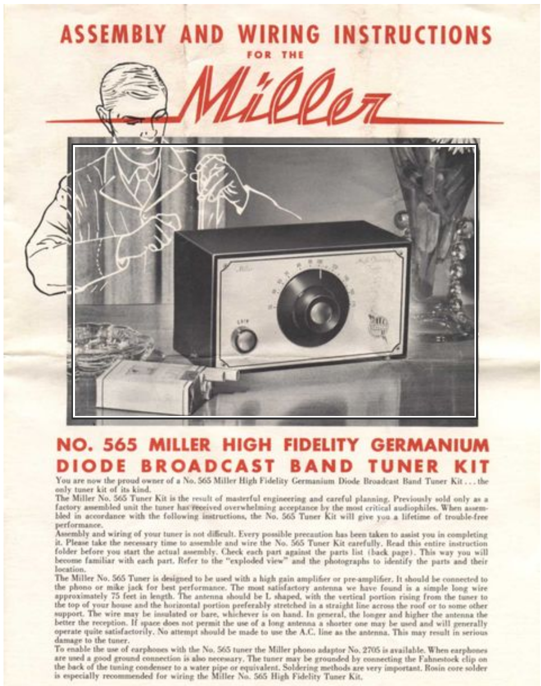
Step 1: Components



ASSEMBLY AND WIRING INSTRUCTIONS FOR THE Miller

NO. 565 MILLER HIGH FIDELITY GERMANIUM DIODE BROADCAST BAND TUNER KIT

You are now the proud owner of a No. 565 Miller High Fidelity Germanium Diode Broadcast Band Tuner Kit . . . the only tuner kit of its kind.

The Miller No. 565 Tuner Kit is the result of masterful engineering and careful planning. Previously sold only as a factory assembled unit the tuner has received overwhelming acceptance by the most critical audiophiles. When assembled in accordance with the following instructions, the No. 565 Tuner Kit will give you a lifetime of trouble-free performance.

Assembly and wiring of your tuner is not difficult. Every possible precaution has been taken to assist you in completing it. Please take the necessary time to assemble and wire the No. 565 Tuner Kit carefully. Read this entire instruction folder before you start the actual assembly. Check each part against the parts list (back page). This way you will become familiar with each part. Refer to the "exploded view" and the photographs to identify the parts and their location.

The Miller No. 565 Tuner is designed to be used with a high gain amplifier or pre-amplifier. It should be connected to the phono or mike jack for best performance. The most satisfactory antenna we have found is a simple long wire approximately 75 feet in length. The antenna should be L shaped, with the vertical portion rising from the tuner to the top of your house and the horizontal portion preferably stretched in a straight line across the roof or to some other support. The wire may be insulated or bare, whichever is on hand. In general, the longer and higher the antenna the better the reception. If space does not permit the use of a long antenna a shorter one may be used and will generally operate quite satisfactorily. No attempt should be made to use the A.C. line as the antenna. This may result in serious damage to the tuner.

To enable the use of earphones with the No. 565 tuner the Miller phono adaptor No. 2705 is available. When earphones are used a good ground connection is also necessary. The tuner may be grounded by connecting the Fahnestock clip on the back of the tuning condenser to a water pipe or equivalent. Soldering methods are very important. Rosin core solder is especially recommended for wiring the Miller No. 565 High Fidelity Tuner Kit.

What you need:

- Epoxy board, or any non-conducting board (for motherboard)
- Metal board (for frontboard, I chose dural)
- Old ugly log (for case)

Electronic parts:

Resistors:

- R1 - 100 kOhms
- R2 - 1 MOhms potentiometer

Capacitators:

- C1 - Tuning capacitator 2 * 500 pF (from an old AM radio)
- C2 - 100 nF
- C3 - 200 pF
- C4 - 50 nF
- Cc1 - 15 pF
- Cc2 - 10 pF

Coils:

- L1 - 250 uH
- L2&L4 - 330 uH (100 turns with 0,21 mm wire on 7 mm in diameter and 29 mm lenght ferrite stick)
- L3 - 20 - 30 double turns on 8 mm in diameter 40 mm lenght wooden dowel, then solder left end of A turning and right end of B turning together
- L5 - 2,5 mH

One germanium diode

Note: Be precision while you are winding the coils. After winding is good to measure the inductive of coils. The inductive has to be the same. It is important for future quality receive.

Other:

- Some wires
- Some banana jacks (for antenna, groung, earphones..)
- Long (best 20 meters) antenna
- Good ground (metal heating is fine)
- High Z earphones (best about 1-2 kOhm or more)
- A lot of chocolate (for patience :))

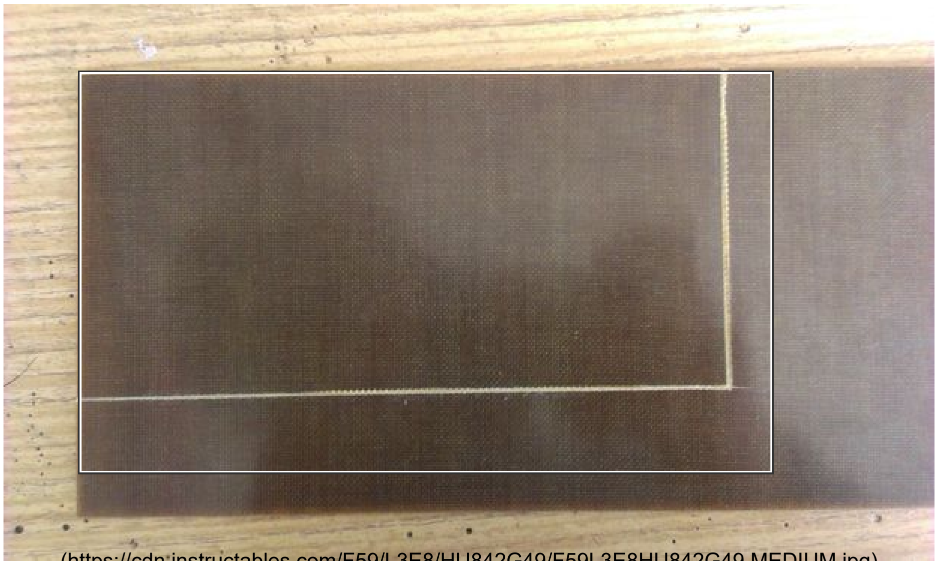
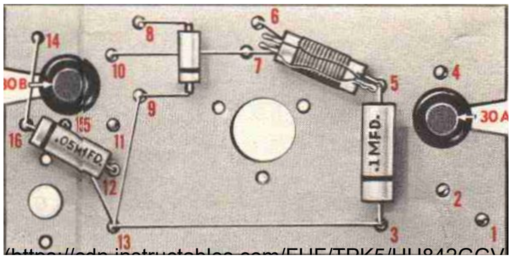
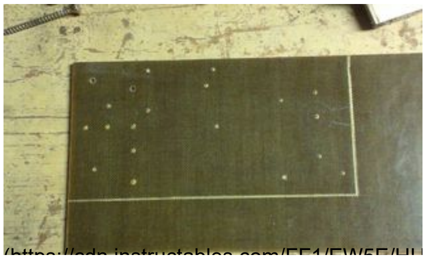
Step 2: Motherboard



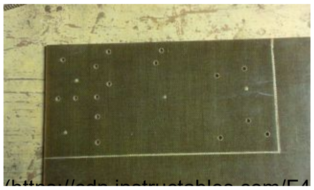
(https://cdn.instructables.com/F59/L3F8/HU842G49/F59L3F8HU842G49.MEDIUM.jpg)



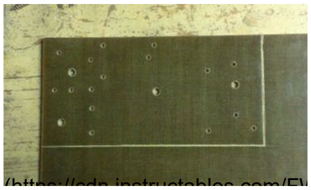
(https://cdn.instructables.com/FHE/TPK5/HU842CGV/



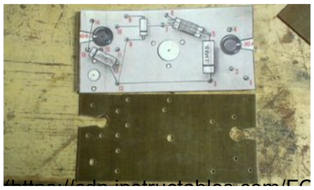
(https://cdn.instructables.com/FE1/EW5F/HU



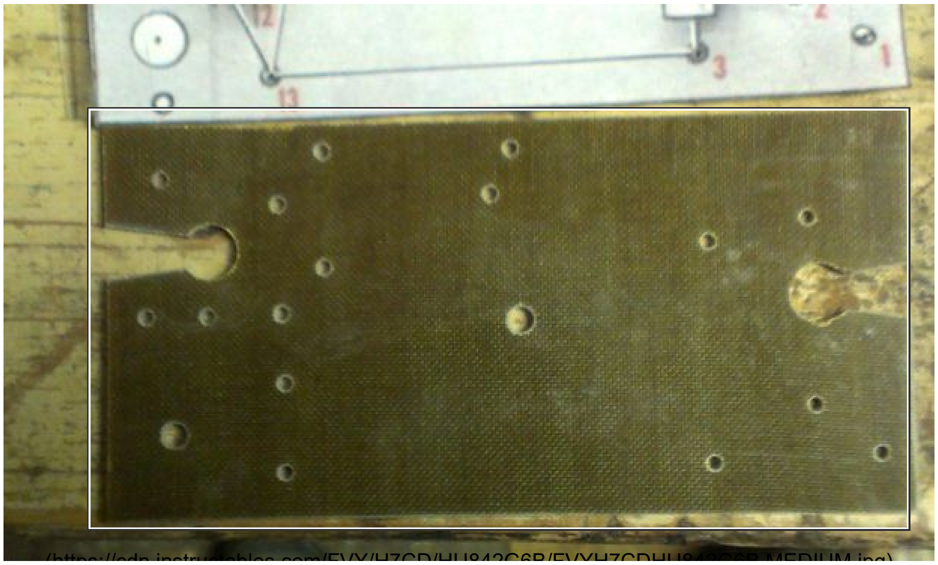
(https://cdn.instructables.com/F4



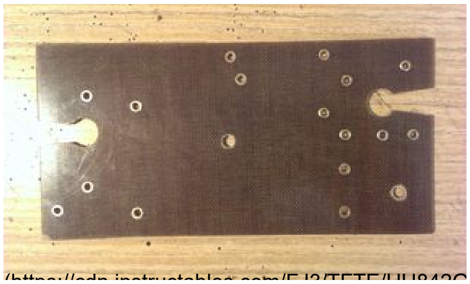
(https://cdn.instructables.com/F\



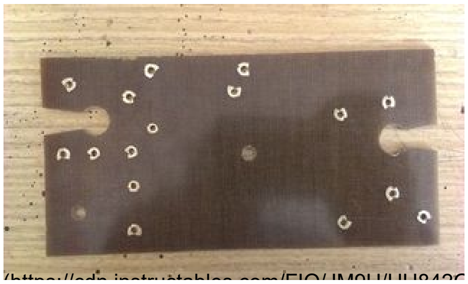
(https://cdn.instructables.com/FC



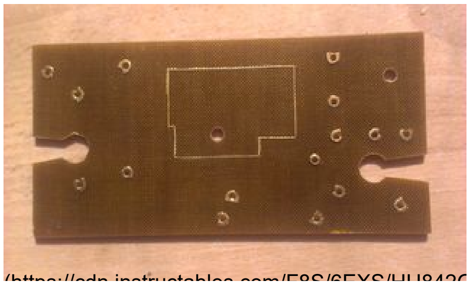
(https://cdn.instructables.com/FVY/H7CD/HU842G6B/FVYH7CDHU842G6B.MEDIUM.jpg)



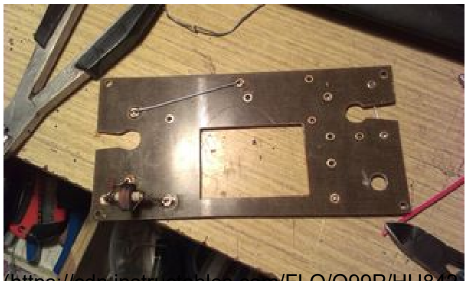
(https://cdn.instructables.com/FJ3/TFTF/HU842C



(https://cdn.instructables.com/FIO/JM9H/HU842C



(https://cdn.instructables.com/F8S/6FXS/HU842C



(https://cdn.instructables.com/FLQ/O99B/HU842

To make a motherboard for the reciever you need comprextit board (or any thin non-conducting board, wooden, platic...). Dimensions of the motherboard are 144 mm * 72 mm.

1. Line the cuprextit board.
2. Print the layout from original manual on paper.
3. Stick the printed layout on the coprextit board.
4. Mark the soldering holes with center punch.
5. Drill all holes you need,
6. Make holder for the ferrite core coils (L2, L4).
7. Rivet the soldering holes with hollow brass (or any solderable metal) rivets.
8. Make BIG hole for the tuning cap!
9. Be happy of the result, you made the motherboard!! :))

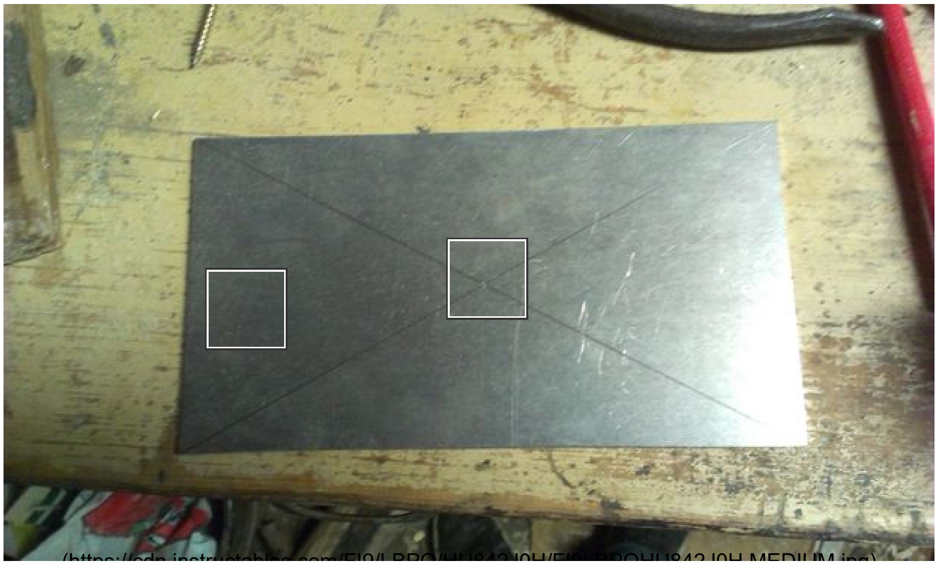
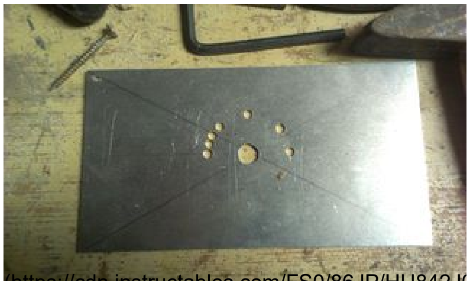
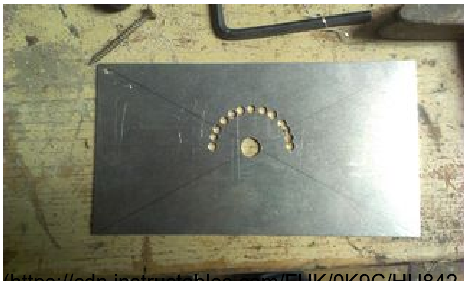
Step 3: Frontboard



(https://cdn.instructables.com/FI9/LBRO/HU842J0H/FI9LBROHU842J0H.MEDIUM.jpg)



(https://cdn.instructables.com/FS0/86JB/HU842J



(https://cdn.instructables.com/FHK/0K9C/HU842

To make the frontboard I choosed dural board. It is not necessary, I just had what I had.

1. Frontboard dimensions are 170 mm * 90 mm.
2. Cut it!
3. Mark it in the center and drill hole.
4. Making some interesting things for good working cap (ellipse, holes..).
5. Make hole for potentiometer (by your motherboard).
6. More holes for future case.
7. By the Motherboard make into Frontboard 4 holes for some screws
8. Be proud od yourself! :))

Step 4: The Case

SEA CHANGES
SCIENCE IN GERMANY
WASTED LIVES AND MONEY
LONG-DISTANCE INFORMATION

The original case is made from bakelite. I can't make it, so I decided to make it from the best material on the world, from the wood!

1. Find log (I found old, ugly log, to prove, that the ugly, old log with mushrooms init doesn't worth nothing, I didn't wanna to kill tree :((..please, respect the nature:)) BTW. I thing the tree is **Populus alba**.
2. Saw this log on right lenght. Side boards are 104 * 78 * 14 (lenght * width * thickness) in mm. Bottom and upper boards are 174 * 78 * 14 mm (first piece of log is shorter (104 mm), second one is longer (174mm)). (P.S. Be sure, this is aesthetics matters)
3. Saw it on Boards. Line the log with right dimensions from the middle of log. Once you have it, next step is comming!
4. Cut it on the one side, then in the middle, and on the end on the other side. Now you have 2 wooden boards. Repeat it with the second log.
5. Smooth it to soft and clean surface. (don't do it with sandpaper, it's not nice. I did it with drawknife (or jack-plane), and result was perfect)
6. Cut it on the right dimensions (lenght, width).
7. Sketch and saw dovetail joints (25 and 12,5 mm). Be precise, I choosed 2 dovetail joints on one side.
8. Assembly the BOX!
9. Time to puttying. The putty consist saw dust and glue for wood or paper (everybody knows that white liquid). The putty is for the holes in the case. After puttying, let it dray about 4-7 days, for sure, than sand it with sandpaper, but carefully. :)
10. So, we've got a case. Let's lacquer. I choosed "Boad lacquer", it has nice a bit orange color, for this old, ugly, white wood is good. Inside took only one layer. Outside took 4-6 layer of lacquer.
11. Let it dry, and be happy! :))

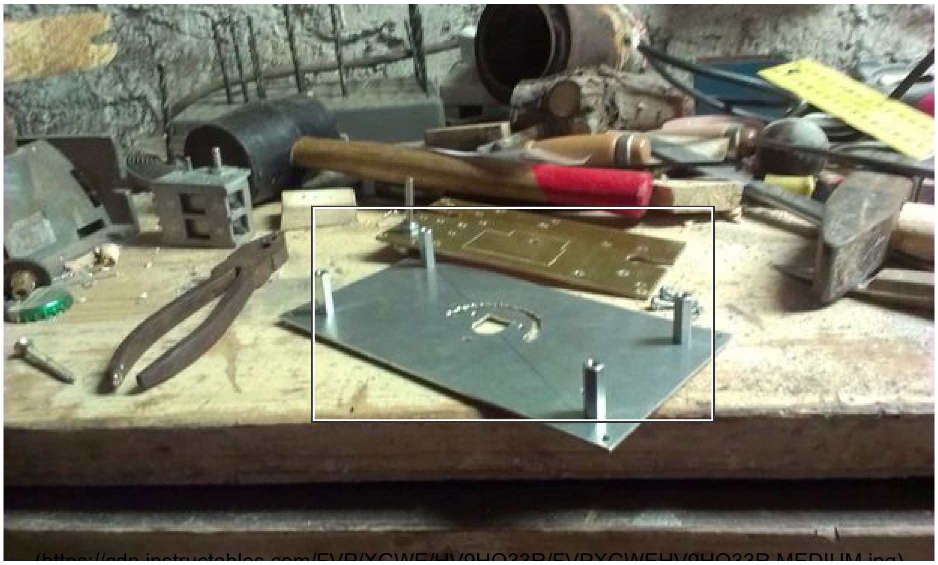
Once you've got motherboard, frontboard and case for radio done, it's time on electronic part!

1. First, collect your electronic parts from step 1
2. Build your alfa version of crystal tuner (this step is not important, you can skip it!)
3. From original instruction lists you can find where every component has be placed. By numbers on schematics (this numbers are also on motherboard layout on original instructions), you will find every single soldering point on motherboard, so, just go on! :)
4. Now, you can solder and solder! First is good to solder wire interconnections. Then you can solder other components.
5. Another step is about coils holders. I didn't know how to solve this problem. In original, they use special rubber holders. I didn't have them. I used rubber holder from old pen, it works fine. Just look at pictures, it will say everything. :)
6. Finish funcional/electronic part, add some ground wires (on tuning cap for example in my case)
7. Done!..?

Step 6: Assembling



(https://cdn.instructables.com/FVB/XCWF/HV9HO33R/FVBXCWFHV9HO33R.MEDIUM.jpg)

We have already finish, just assemly all parts into the case!

1. I chose solution with screwed mothorboard with frontboard, then frontboard is screwed with case. It's becaouse it is the siplest way for repearing/assembling/disassembling and also, I had not a good tuning cap for this case.
2. Pictures will say the same. :3

Step 7: Final Touches!

This is the last step. You can add some buttons on potentiometer, or tuning cap, add some bannana jacks for antenna, ground and headphones and so on. That's only on you!

This is the end! Thanks for your time!

If you like my project, you can support me on facebook https://www.facebook.com/pages/D-Fox/236623253020... (https://www.facebook.com/pages/D-Fox/236623253020320?ref=hl) , or on instagram http://instagram.com/ondrej_fidra (http://instagram.com/ondrej_fidra) .

Respect the nature!

Peace!

Instead of having the antenna drapped around, couldn't THAT be coiled around a tube also?

spark master (/member/spark+master/) 2014-05-22 Reply

Oh I fergit, if you have acess to formica or thin slate or anything non conductive you can build right on it. Stuff like this was built on wood, that was shellacked a few times or shellacked then waxed, or might be build on a chunk of (yikes) soapstone or an old tile.

But usually it was wood. As long as it was non ferrous, non conductive and not subject to water retention, it was good to go. On a few I just screwed the components to a block of scrap wood, then put it on an antenna or Arial .

A note on antenni, as ham's will tell you height makes maight and size matters.

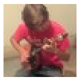
The higher you get the antenna or the bigger it is the better it will work. Also if you get your antenna feed up high instead of one wire x feet long use 3 -4 all parallel that will snag more micro volts from the air giving you more energy into the detector circuits and headphones.

And

the better you ground this thing, the better it will work. For a really good ground bury a 1957 GM car (any one will do), at least ten feet below the ground attaching #8 stranded wire to it, back fill with lightly salted sand with a sprinkling of iron filings soak well with salted water and then put finished ground cover, water daily.

If that is unavailable,,,cold water pipes are sufficient.

they don't call me sparkie fer nut'n



DiggingFox (/member/DiggingFox/) ▸ spark master (/member/spark+master/) 2014-05-23 Reply

Antenna and ground are very important. If you've got better antenna and ground, you've got better sound and selectivity! I've got about 20 meters long antenna in 30 meters, and it's fine (sometimes is very dangerous! when the storm comes!)

Thanks for your comments! 73!

spark master (/member/spark+master/) 2014-05-22 Reply

here is a page that has the same jpegs, but can be enlarged enough to read them

I have built a number of Xtal Radios and they are fun, but where does one purchase old huge variable caps?

You can make them (albeit they may be a tad crappy, or you may need to experiment to get the right capacitance), or if you find old dumped radios you are good to go. It has been years , but I thought the tuner was about 360 MFD's or so. Great project!

DiggingFox (/member/DiggingFox/) ▸ spark master (/member/spark+master/) 2014-05-23 Reply

Thanks! The best way to get the big caps is take it from old damaged radios (don't kill them!! old radios are jewelery!! look at the design!!)...but, this cap has about 300 mmFD on each side, 500 mmFD on each side is better!

manohar (/member/manohar/) 2014-05-20 Reply

could you please provide the circuit diagram for electronics.

DiggingFox (/member/DiggingFox/) ▸ manohar (/member/manohar/) Reply 2014-05-20

Hi! Circuit diagram and schematic is in step 1, in original instructions.

Tommy_tux (/member/Tommy_tux/) 2014-05-20 Reply

Very nice design... Maybe you can build in a web radio? Thanks for this idea...

DiggingFox (/member/DiggingFox/) ▸ Tommy_tux (/member/Tommy_tux/) Reply 2014-05-20

Tkanks you! Yea, I could, I am working on web radio with STM32, but it's too hard for me, I have to learn more about it :)

Reply 2014-05-18

Nice project and nicely presented. Love your sense of humor and I wish I could communicate as effectively in Czech as you can in English. Enjoyed reading and following your Instructable! I found myself smiling with admiration for what you made, and that you took time to share it here. Did you use that back saw that is visible in the photo to cut the pieces of wood? [That must have been fun!] And where did you you come across the old plans for the radio? [the internet?] How much chocolate is needed! :)

DiggingFox (/member/DiggingFox/) ▸ plantprof (/member/plantprof/)

Reply 2014-05-19

Thank you! yes, I used the saw visible on the fotos (with the orange handle), the plans are from the internet, of course :) I am a bit chocoholic, I ate about 10 bars od chocolate :D hope, you like it :)

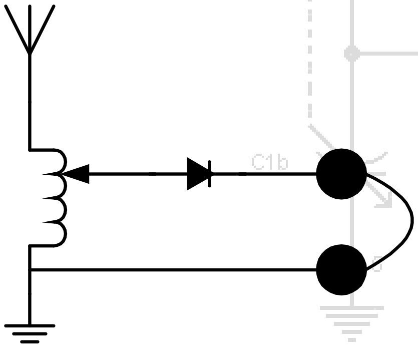
Don Asquin,

Gord Rabjohn

(Presented by Gord at the Ottawa Electronics Club, April 2012)

Childhood History

www.crystalradio.net



- Like many kids, I had frustrating childhood experiences with crystal radios!
- Simple crystal sets couldn’t separate multiple AM radio stations.
- Only local stations were received, and everything was received all at once.

Rediscovering History

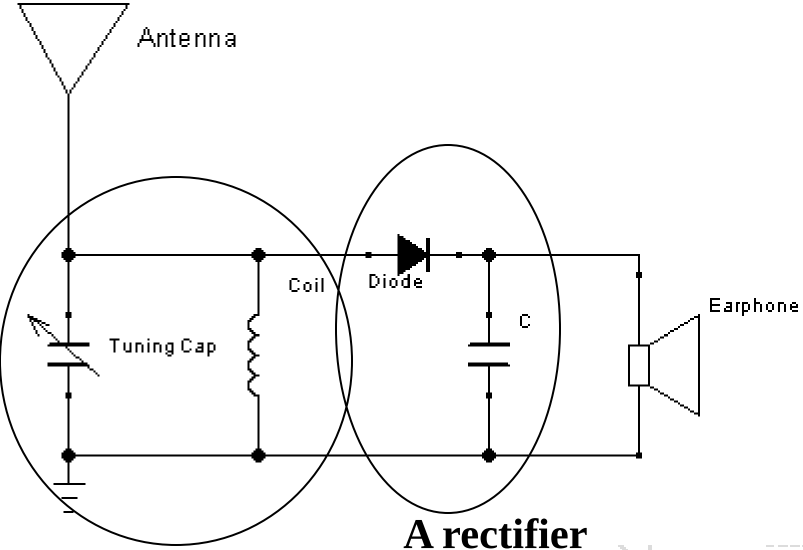
www.crystalradio.net

- Recently, my friend Don Asquin and I decided to build high performance crystal sets.
- Much of this exploration is rediscovering the knowledge of the 1910s and early 1920s.
- Even then there were claims of DX performance with crystal sets.

How does a basic crystal set work?



Antenna
Coil
Diode
Tuning Cap
C
Earphone

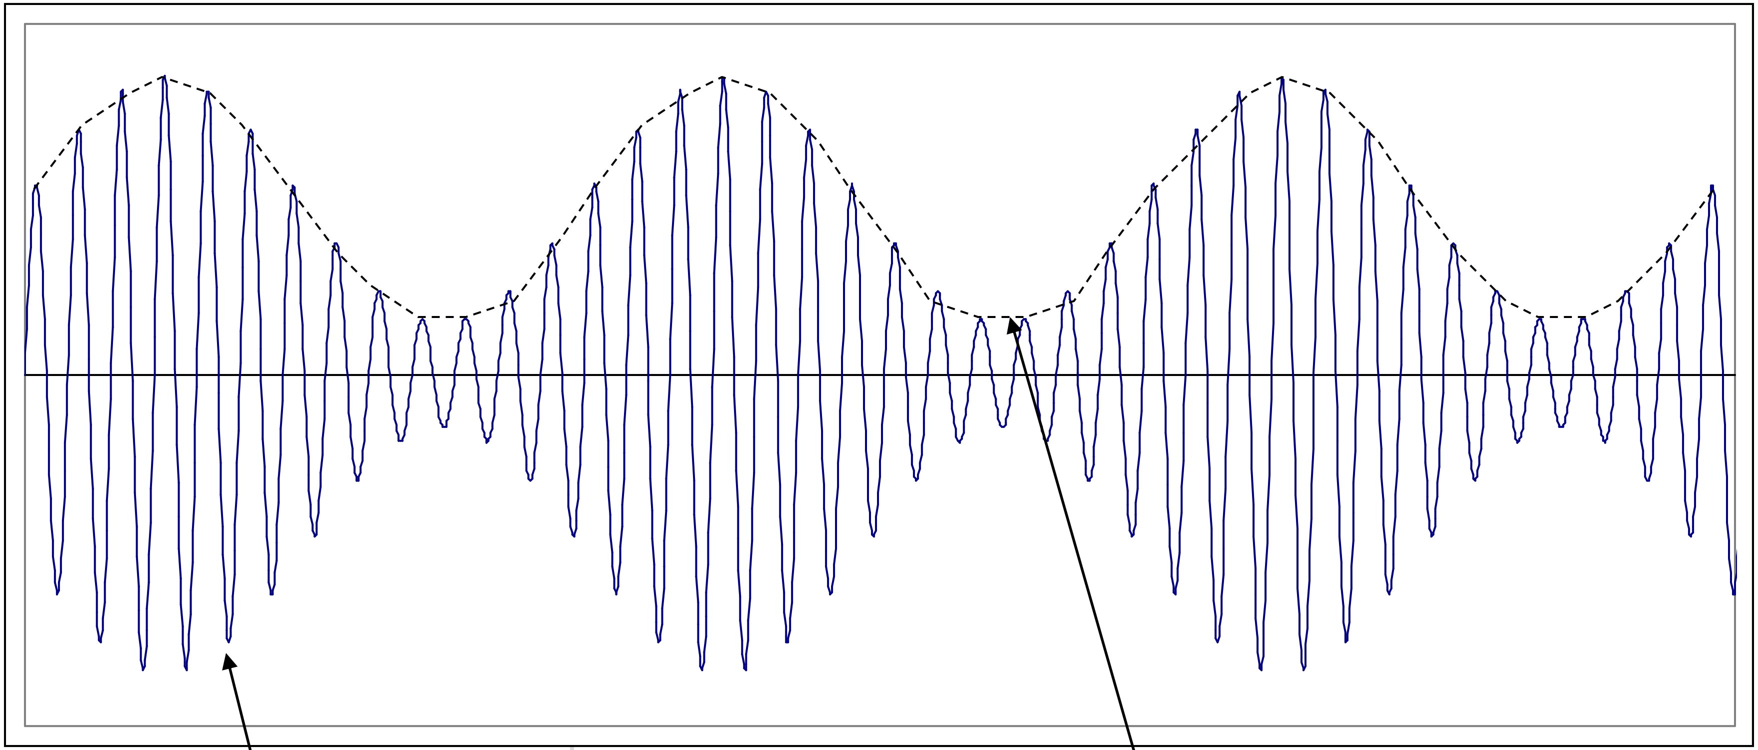
A rectifier

A filter

At low frequency, the inductor shorts the signal out. At high frequency the capacitor shorts the signal out. In-between, there is a magic point called "resonance"

- Antenna couples to the (usually) electric field in a radio wave.
- L-C selects the frequency.
- Diode rectifies it.
- Earphone makes it audible

AM modulated signal



RF Carrier frequency (say 1310kHz): the filter selects only this frequency.

Rectified audio output, smoothed by the capacito

The Four Key Elements

ANTENNA
Federal Jr.
www.crystalradio.net

www.crystalradio.net

- Antenna
  - Antenna
  - Ground
- Tuner
  - Loose coupler
  - High Q coils
  - RF impedance matching
- Detector
- Audio Transducer
  - Audio Impedance matching

Antenna

- A long exterior antenna is crucial.
- Why? It’s not just about area… “watts per acre”. It’s also about giving the antenna a better “radiation impedance”.
  - The energy from an antenna, can be modeled as a voltage source in series with a source resistance (or a current source in parallel with a source conductance), and the antenna capacitance (or inductance).
  - Radiation resistance is the resistance of this apparent source of energy in an antenna.
  - The tuned circuit matches this impedance to the load (detector) for optimum energy transfer.
  - A small antenna will tend to look like a “difficult to match” impedance….

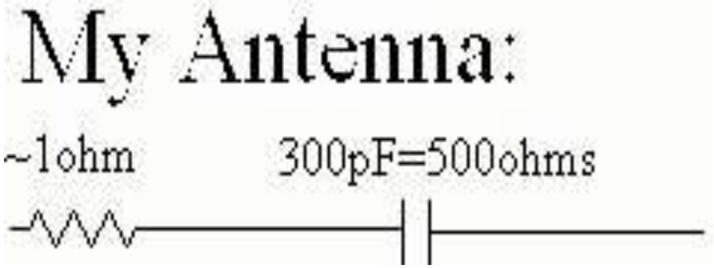
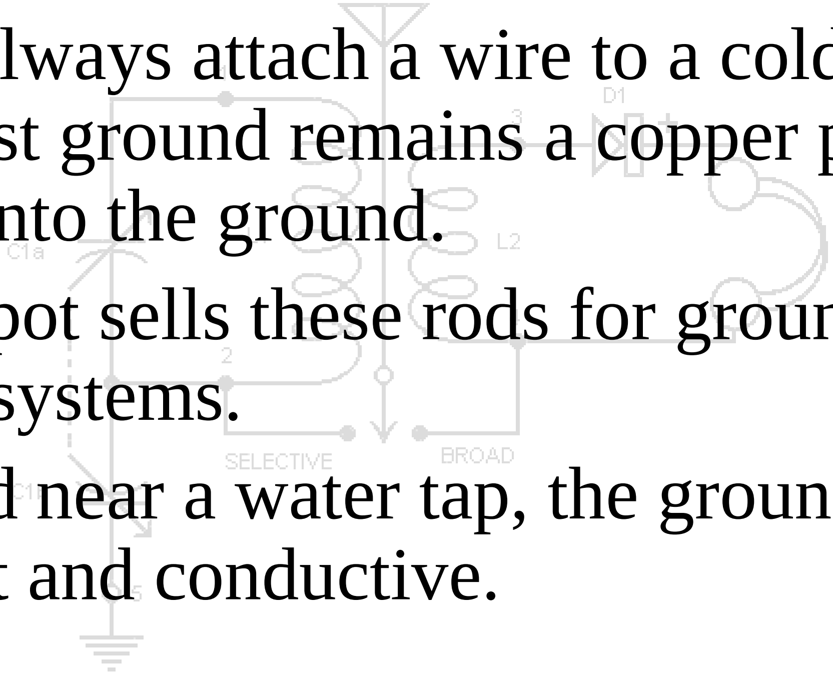
5



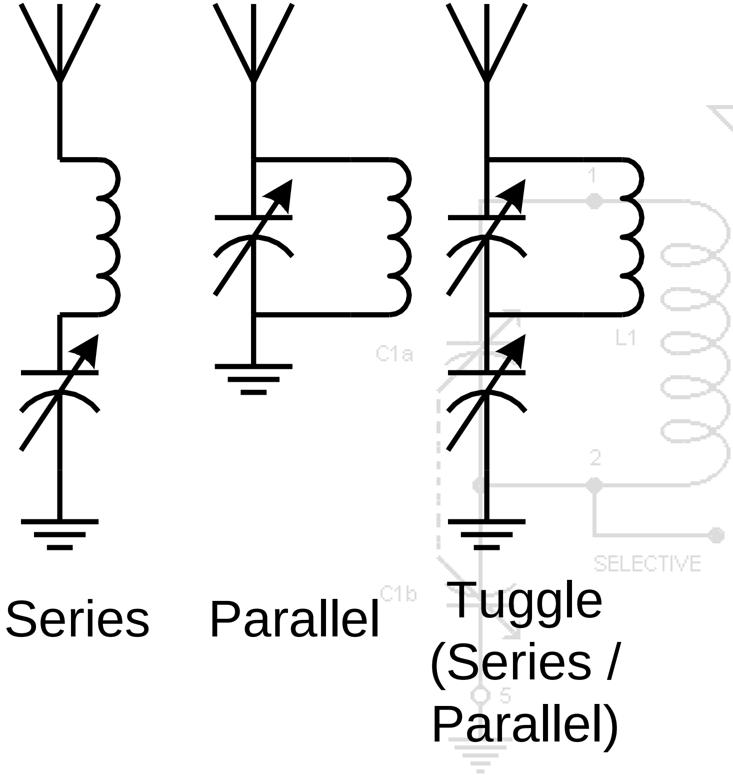
My Antenna:
~1ohm
300pF=500ohms

⏚ Ground ⏚

- The ground provides the completion of the current path for the radio signals.
- You can always attach a wire to a cold water pipe, but the best ground remains a copper plated rod pounded into the ground.
- Home Depot sells these rods for grounding electrical systems.
- If installed near a water tap, the ground can be kept moist and conductive.



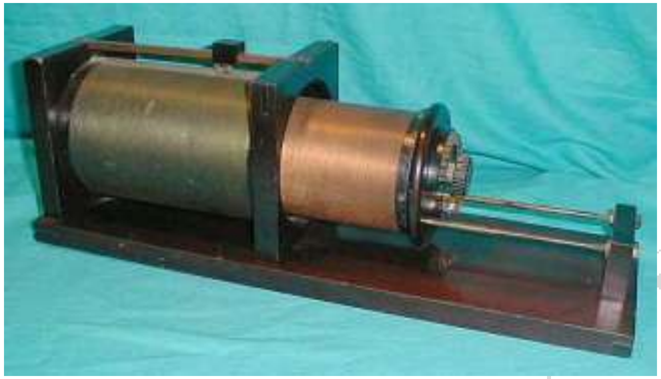
Tuner
-Antenna Tuner



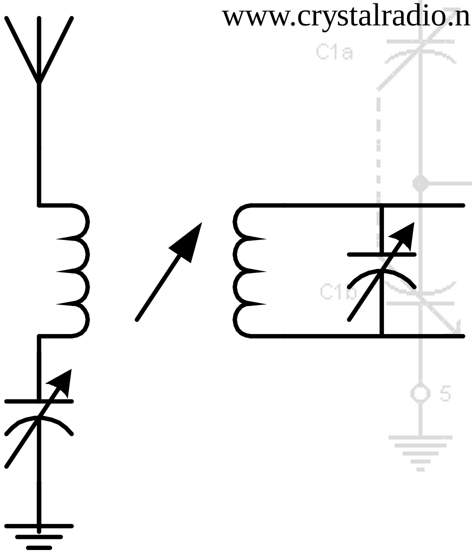
Series
Parallel
Tuggle
(Series /
Parallel)
C1a
C1b
L1
L2
SELECTIVE
BROAD
1
2
3
4
5

- To extract the most power, you need to match the resistance of the load (detector and earphone) to the impedance of the source (antenna)
- The function of the tuner is to match the radiation resistance of the antenna to the impedance of the detector, and to provide selectivity.

Tuner
-Loose Coupler

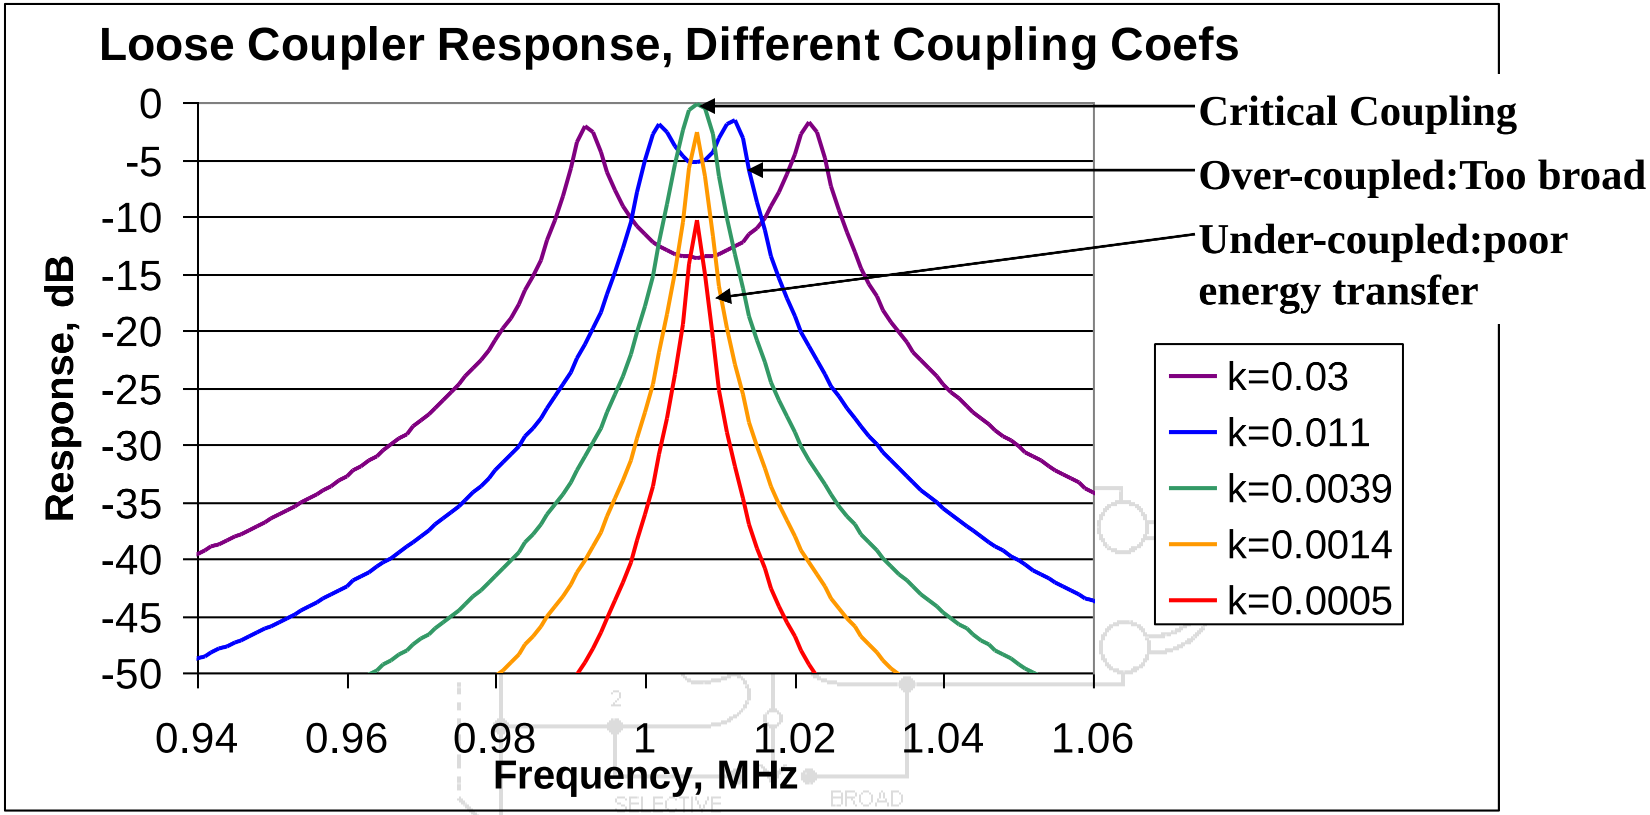


www.crystalradio.net



- The loose coupler is simply two coils (each generally resonated with a capacitor) lightly coupled to each other.
- One coil is connected to the antenna, the other is connected to the detector.
- Even cheap capacitors tend to be quite good, but high Q inductor fabrication is an “art”.

Loose Coupler



Critical Coupling

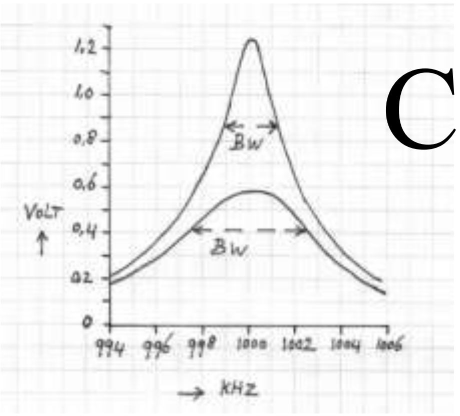
Over-coupled:Too broad

Under-coupled:poor energy transfer

Simulation of 1000pF, 1.0 ohm antenna, 100uH primary coil and ~330pF cap, coupled to a 100uH secondary coil, 250pF cap, 100k load.

- There is an optimum amount of coupling between the coils. (=1/Q). This is VERY LIGHT coupling. Under 1% of the magnetic field is coupled.

Coil "Q" = Quality



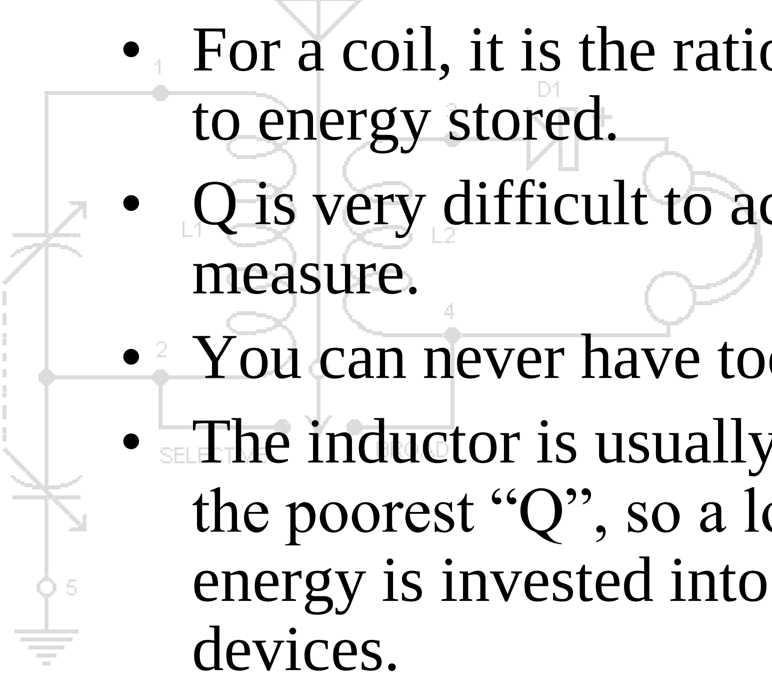
www.crystal-radio.eu

$$Q = \frac{\text{Frequency}}{\text{Bandwidth}}$$

Station Frequency (kHz)	Minimum Q
540	54
1000	100
1600	160

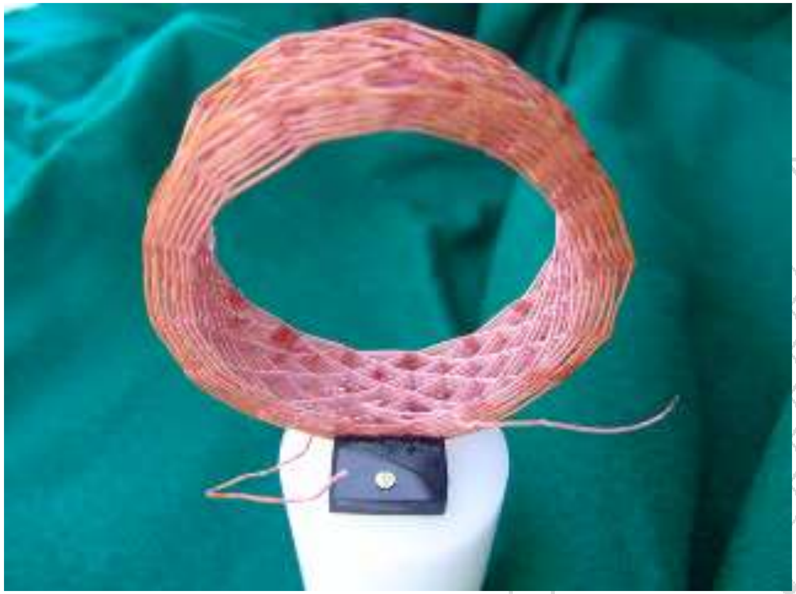
Assume Q=160

Station Frequency (kHz)	Audio Bandwidth (kHz)
540	1.7
1000	3.1
1600	5.0



- For a tuned circuit "Q" is the ratio of the center frequency to the bandwidth.
- For a coil, it is the ratio of energy lost to energy stored.
- Q is very difficult to accurately measure.
- You can never have too much Q!
- The inductor is usually the part with the poorest "Q", so a lot of creative energy is invested into optimum devices.

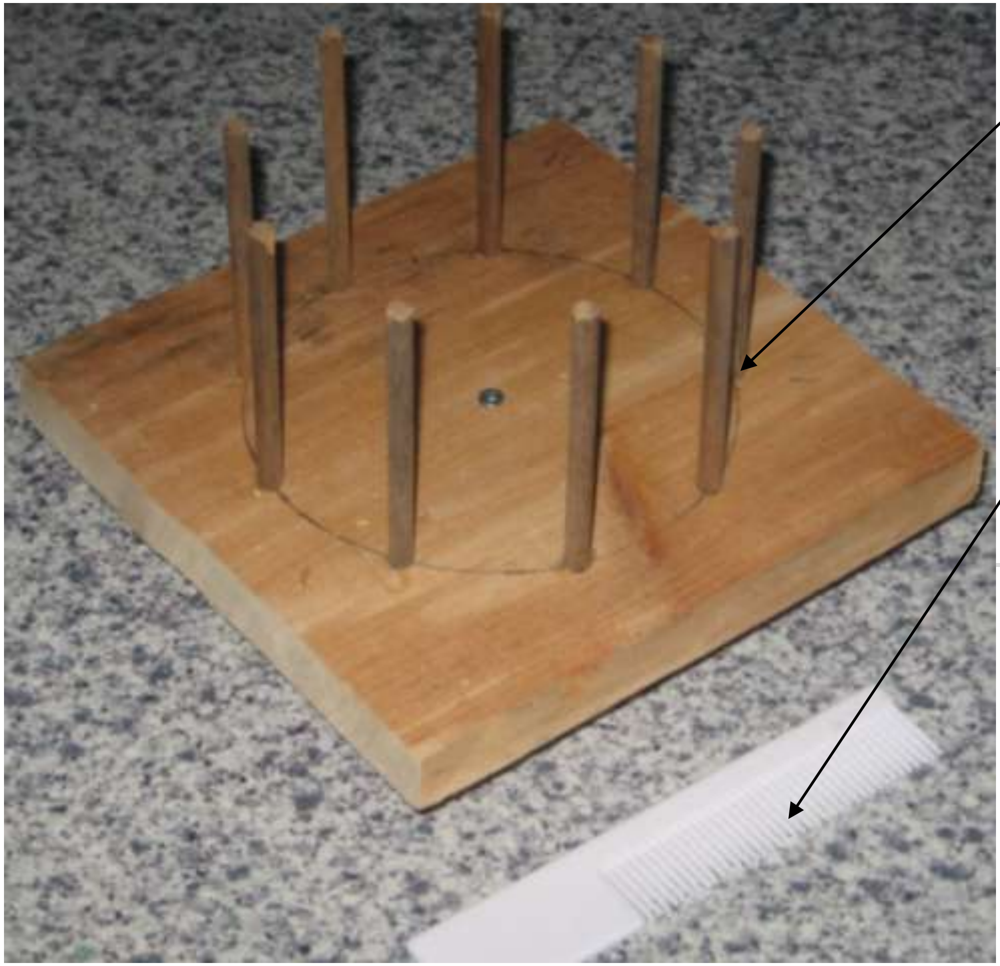
Coil Types



www.wynterarchtops.com

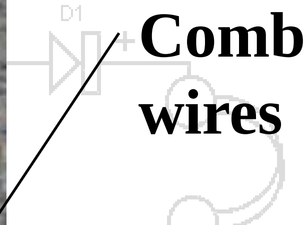
- The highest “Q” coils seem to be air core.
- Many different variations
  - Spider web,
  - Basket weave
  - Honey Comb
- All attempt to reduce capacitance and current crowding to increase Q

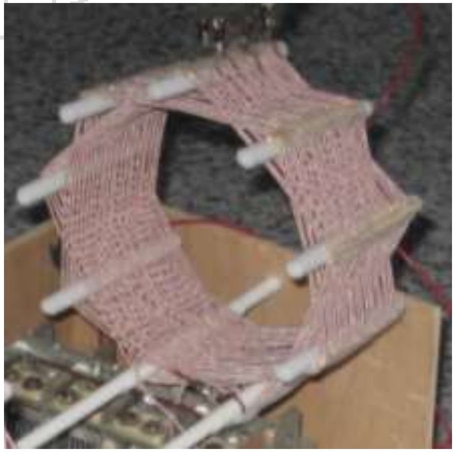
Coil Winding Jig



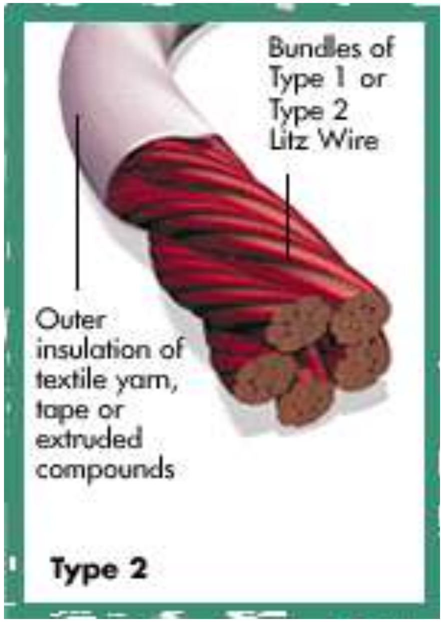
Drinking straws fit over ¼” dowels.

Comb helps space wires





Litz Wire



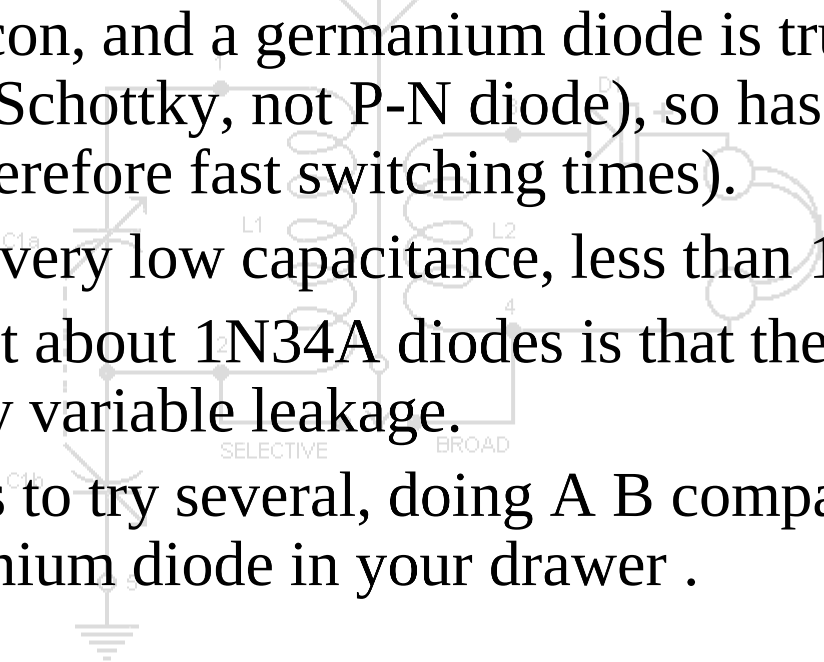
Bundles of Type 1 or Type 2 Litz Wire
Outer insulation of textile yarn, tape or extruded compounds
Type 2

www.newenglandwire.com

- Best wire for high “Q” coils is Litz wire.
- Litz is derived from the German word “Litzendraht” meaning woven wire.
- Consists of many strands of parallel connected, individually insulated wire woven together in a regular pattern.
- Each wire alternates between the middle and the outside of the bundle.
- Each wire forced to carry about the same current, minimizing skin effect (the tendency for current to flow along the outside surface of a wire), and loss.
- The holy grail of litz wire is made up of 420 to 660 individual strands of 46 AWG wire all twisted together to make a 16-18 AWG wire.
- One comparison: A basket wound coil with solid copper wire (~200uH) has a Q of 230 at 1MHz. With Litz wire, it has a Q of over 500!

www.crystalradio.net

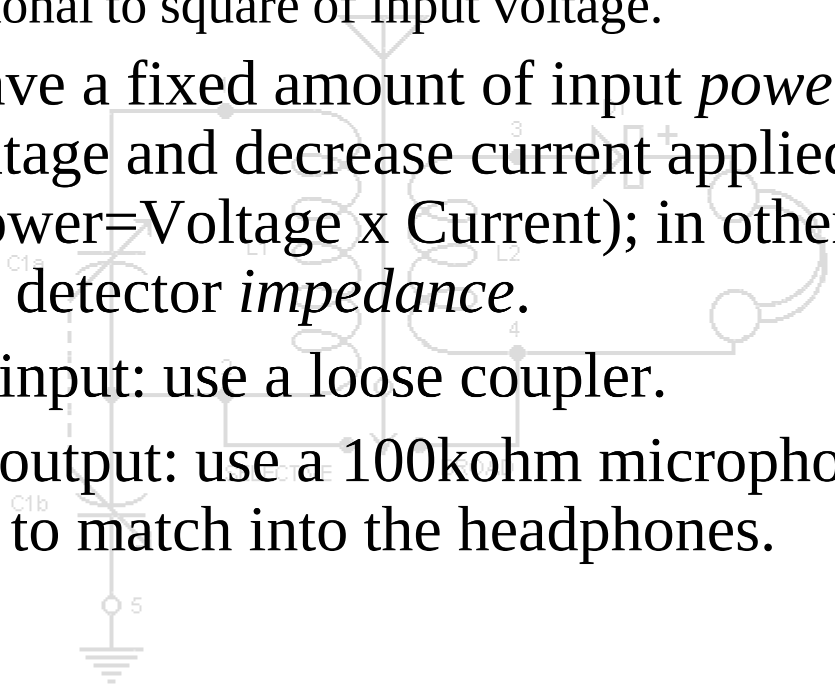
Detector



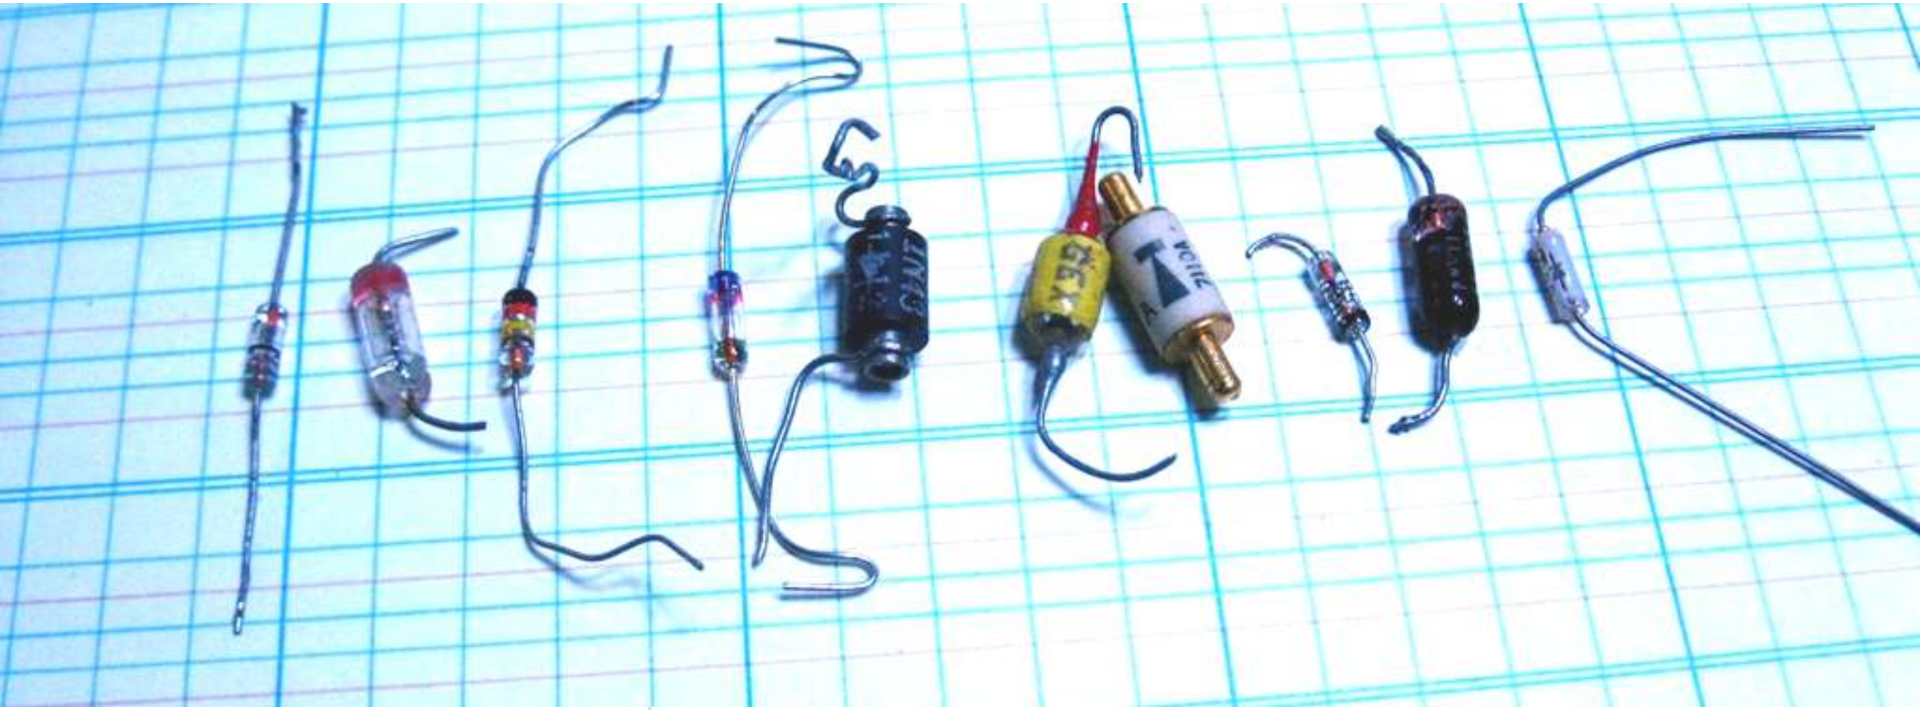
- In my experience, nothing beats a good 1N34A germanium diode. (Still widely available)
- Germanium is good because its barrier height (turn-on voltage) is lower than silicon, and a germanium diode is truly a point-contact diode (Schottky, not P-N diode), so has low charge storage (and therefore fast switching times).
- Specified with very low capacitance, less than 1.0pF.
- Main complaint about 1N34A diodes is that they tend to have high and highly variable leakage.
- Best solution is to try several, doing A B comparisons and select the best germanium diode in your drawer .

Detector Impedance

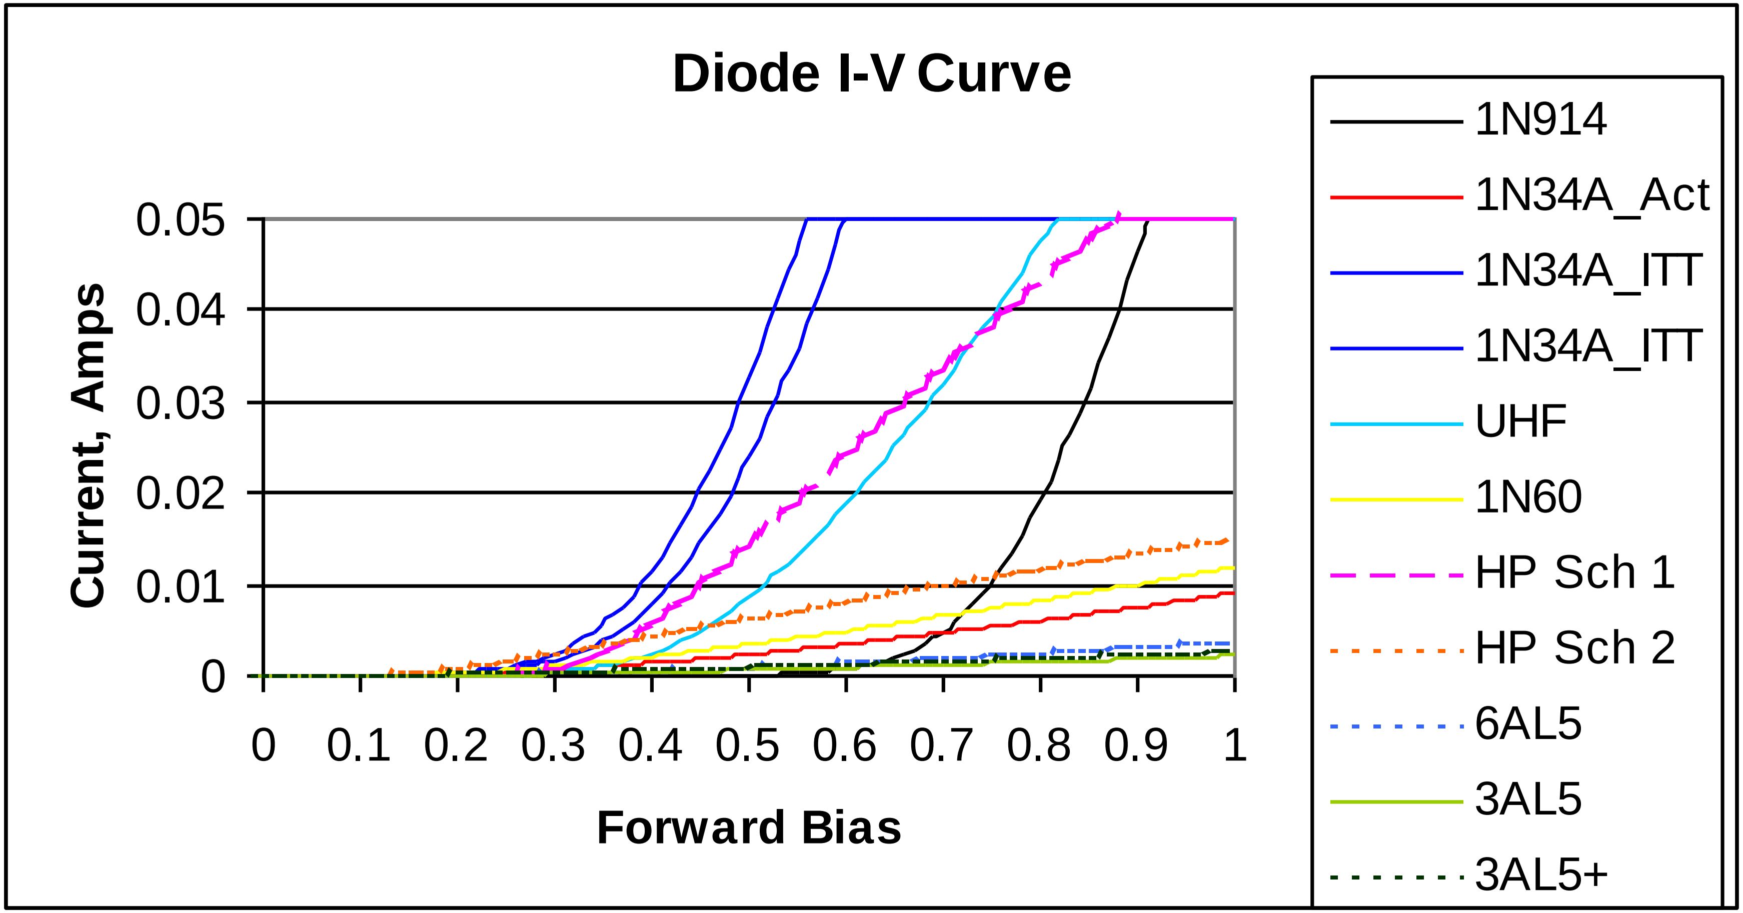
- Detectors are most efficient when driven with *high voltages*.
  - Detectors are “square law” devices (at low power), output voltage is proportional to square of input voltage.
- Since we have a fixed amount of input *power*, we need to increase voltage and decrease current applied to the detector (Power=Voltage x Current); in other words increase the detector *impedance*.
- At detector input: use a loose coupler.
- At detector output: use a 100kohm microphone transformer to match into the headphones.



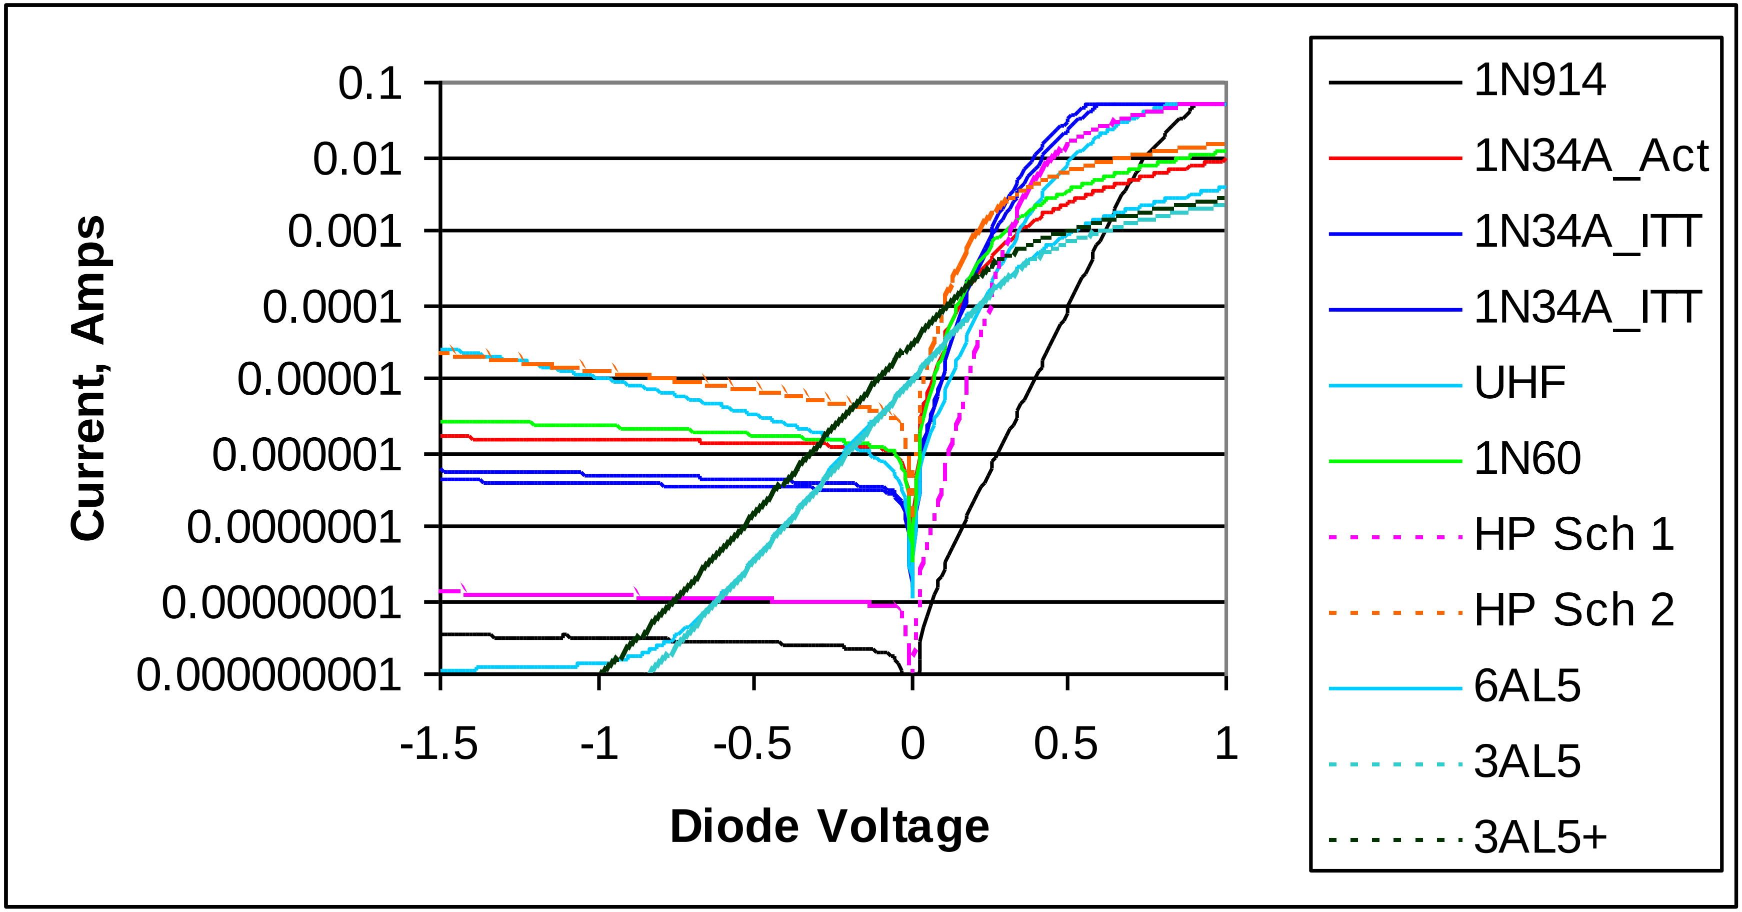
Germanium Diodes



Detectors: I-V Curves

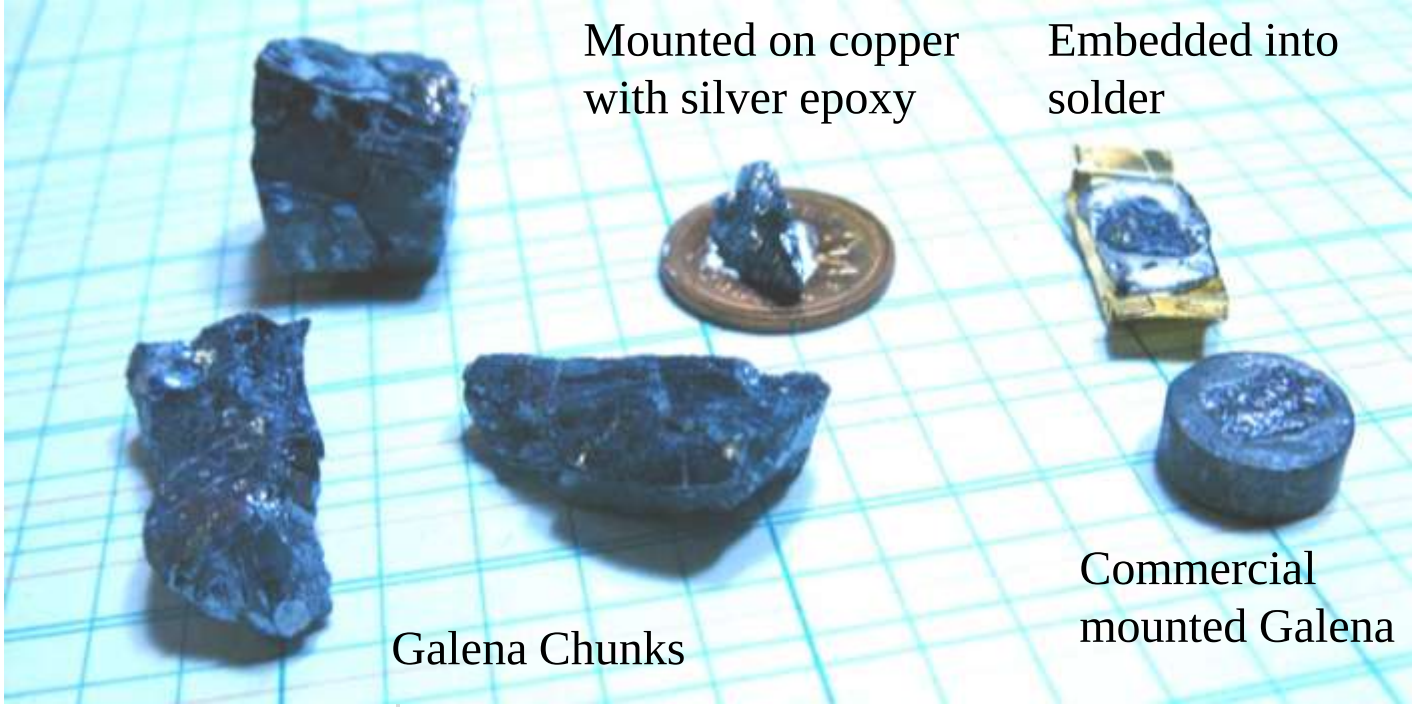


Detectors: I-V Curves



Mineral Detectors

Lead Sulfide, PbS (Galena), Iron Pyrite, Zincite, and other minerals have been used to make detectors (surprisingly good).



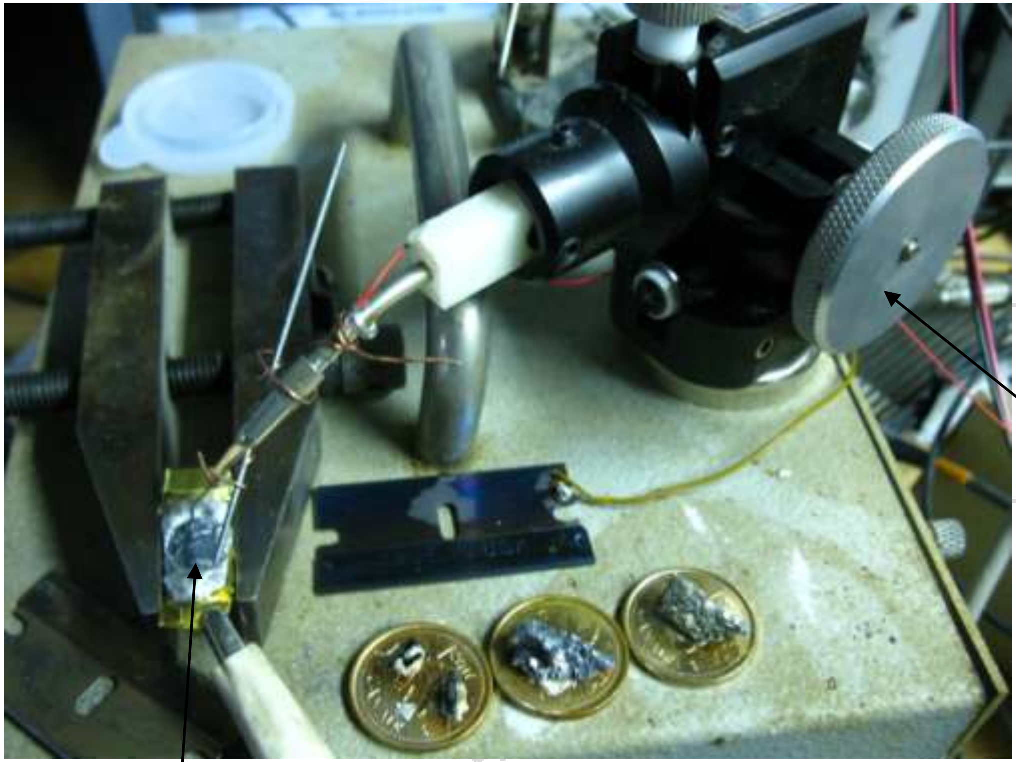
Mounted on copper with silver epoxy

Embedded into solder

Galena Chunks

Commercial mounted Galena

Galena Detector



X-Y-Z manipulator

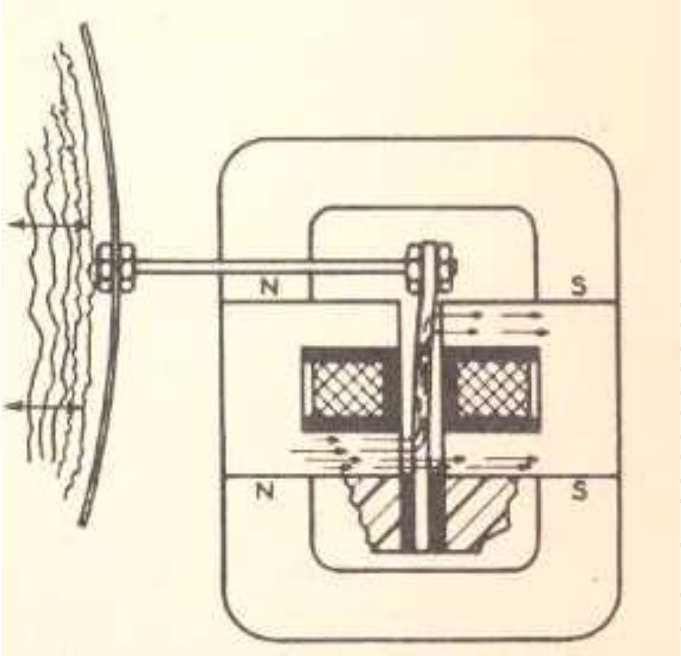
Galena mounted in solder

Audio Transducer

www.crystalradio.net

- Best transducers (headphones) for crystal radio operation are “Sound Powered” headphones or “Deck Talkers”.
- Developed in WWII for the navy to allow communications between the observers and gunners without the need for external power source.
- So sensitive that the pressure of the talkers voice in the microphone is sufficient to drive the headphones of the listener.

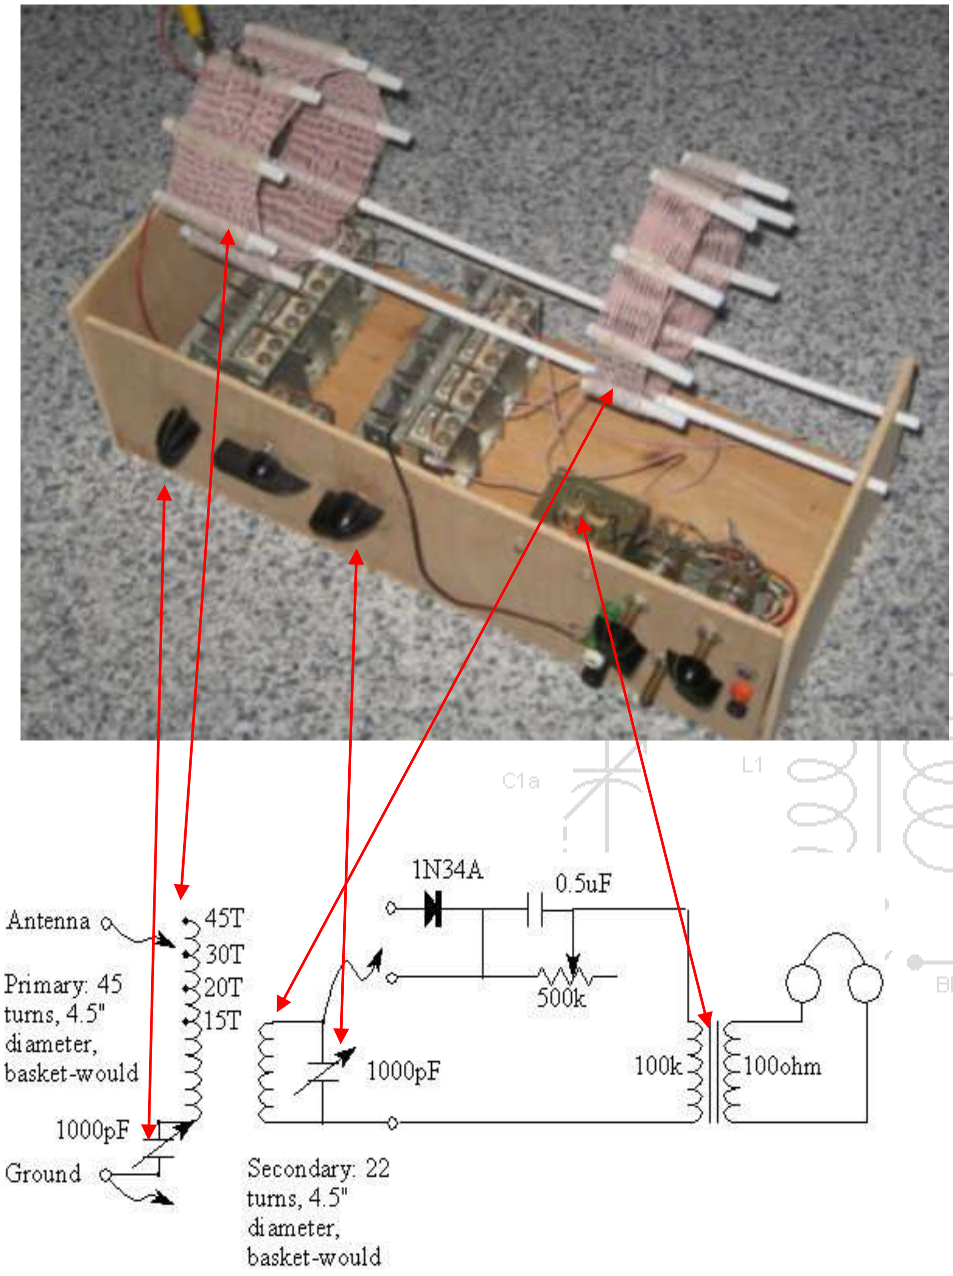
Audio Transducer



www.crystalradio.net

- An elaborate mechanism balanced armature system) give the sound powered headphones their sensitivity.
- Impedance typically around 1000 ohms, much too low for direct use in a crystal set. An impedance matching transformer is essential.
- Microphone transformers are excellent choices for matching the impedance of the diode to the headphones.

Final Results



Antenna
45T
30T
20T
15T
Primary: 45 turns, 4.5" diameter, basket-would
1000pF
Ground
1N34A
0.5uF
500k
1000pF
100k
100ohm
Secondary: 22 turns, 4.5" diameter, basket-would
C1a
L1
L2
BROAD

- Litz wire basket wound with taps for experimentation.
- Series antenna tuner above 650kHz. Below 650kHz, capacitor has to be placed in parallel with the inductor
- Ceramic insulated variable capacitors for maximum Q
- R-C allows DC to build up, reduces detector loading and reduces distortion on local stations.

Clear Channel Stations

- Most of the distant stations we receive are 50,000 Watt “clear channel” stations.
- A clear channel station is a high power American station that shares its frequency with very few other stations
- The realization that a station nearly 1000 miles away can be heard in a completely passive crystal radio is amazing

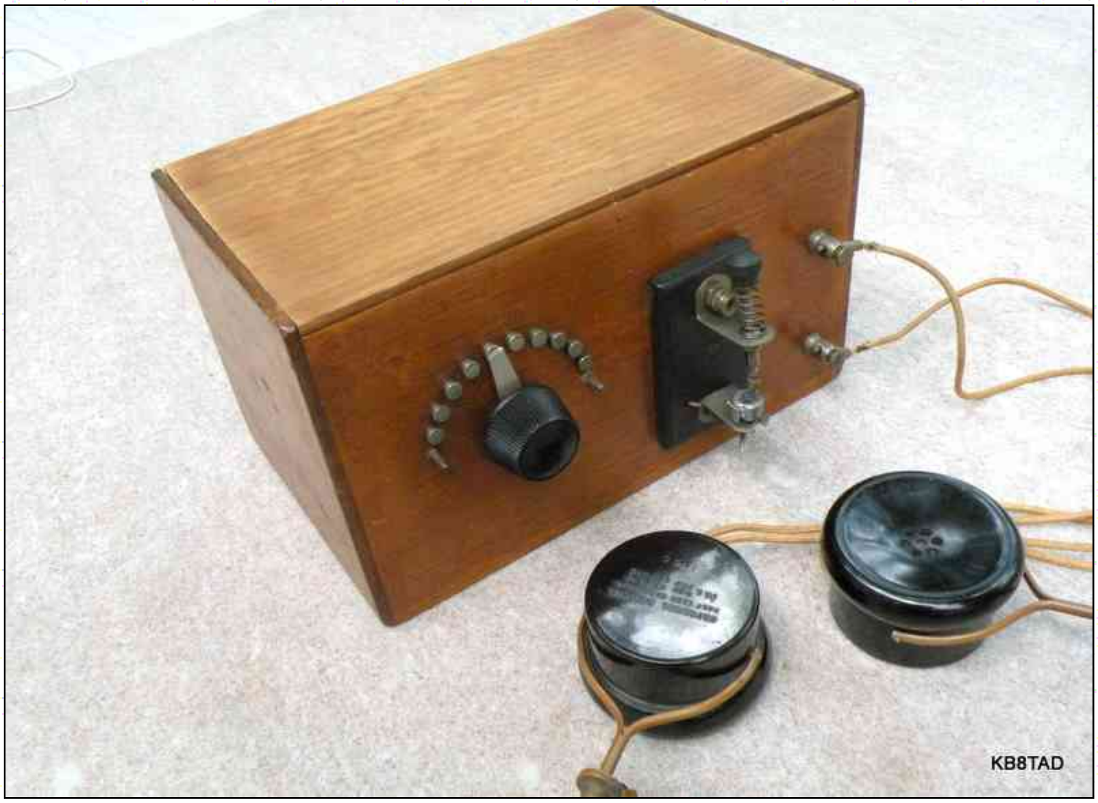
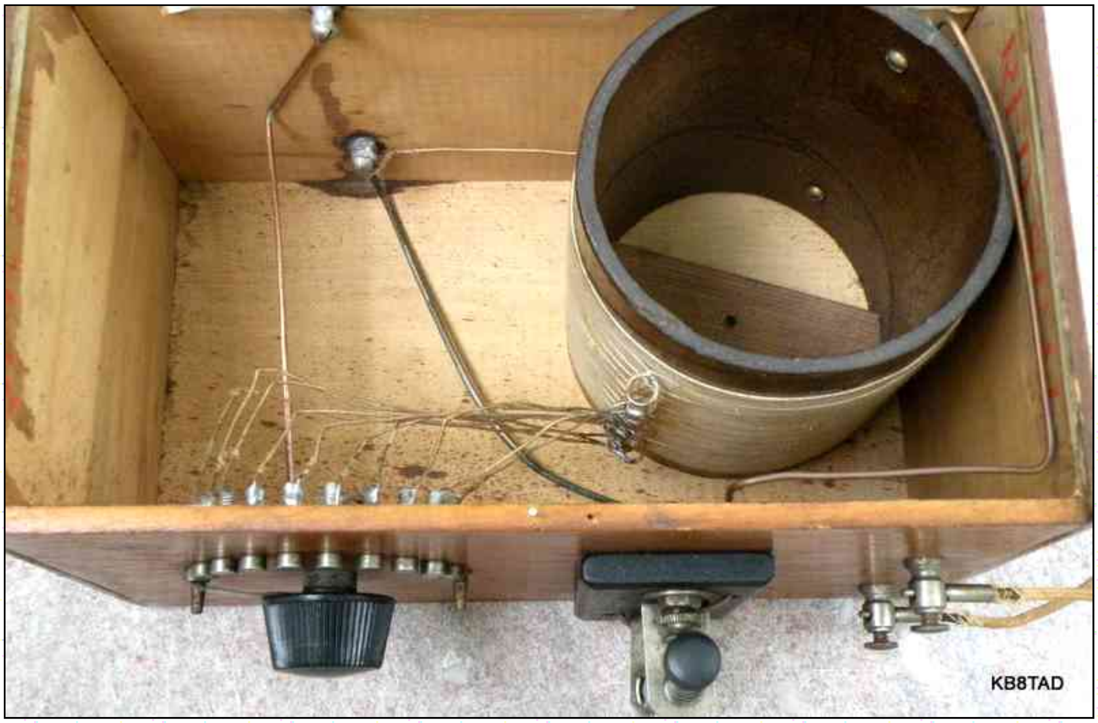
Homebrew Galena Crystal Set

Enjoying a 1920's radio experience

Ever since my youth, I have been attracted to crystal radios I had seen pictured in old books. There is a special appeal about a device, however primitive, that can pull in radio voices and music through the air from many miles away without batteries or electrical power of any kind, just an antenna and a ground.



That explains my immediate attraction to this little homebrew crystal radio with galena detector found at a swap meet. It was built into a deep cigar box using a heavy paper roll as a coil form. The coil form measures 4 1/4 inches long with 3 3/4 inches outside diameter. The coil itself consists of 99 turns of solid double-cotton covered wire tapped every 9 turns. Those taps are fed to ten smooth-head screws that make up the tap selector switch contacts.



Repairs

As with all older electronics, the first repair is a good cleaning, making sure the solder joints are in good shape, and applying a bit of deoxit to all moving electrical contacts, in this case the ten-position tap switch and the crystal holder.

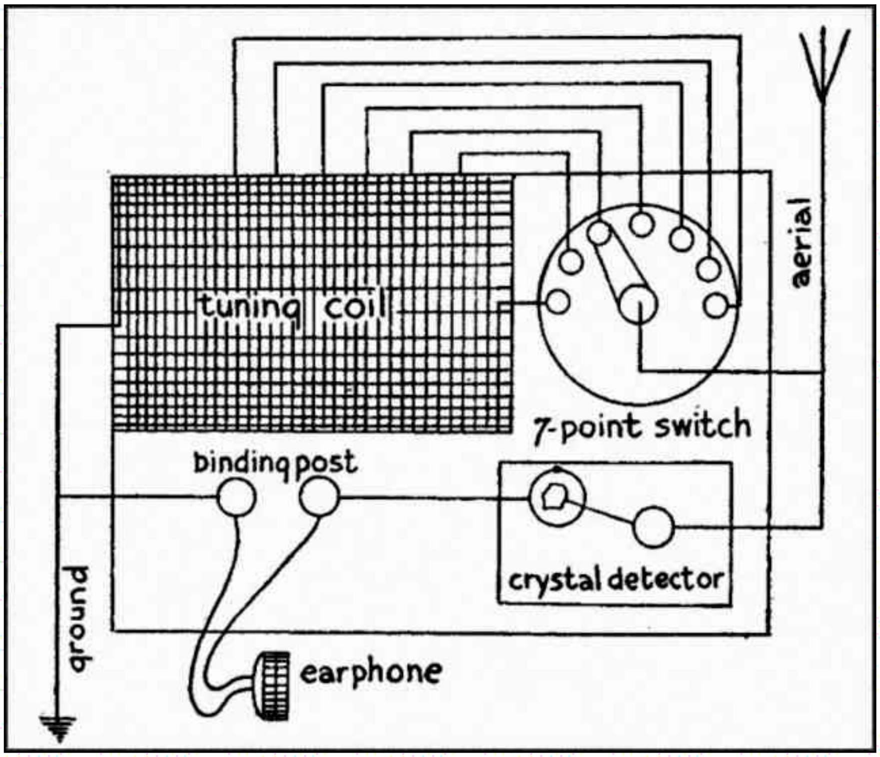
The top of the cigar box had been removed and apparently lost over the years. The cover had been fastened with a small nail which was still on the box. I made a top cover from another old cigar box lid.

The galena crystal was potted in Wood's metal that had separated into two pieces. Quick work with a soldering iron solved that problem. I cleaned the galena surface with rubbing alcohol as recommended in older articles. I then measured forward and back resistance ratios of the galena-and-cats-whisker diode. While there is a signifcant difference between forward and back resistance readings on an ohmmeter, the ratio was nowhere close to that of a modern germanium diode, thus limiting the efficiency of the crystal.

A 1920s experience

I hooked up the set to my 80 meter dipole antenna and listened to the two local AM stations with adequate volume using my equally old but very efficient Baldwin headphones. I could find sweet spots with the "cat's whisker" on the galena crystal that worked reasonably well. However, connecting a 1N34A germanium diode in series with the headphone lead to the galena crystal made a major difference. I could see why the introduction of fixed germanium diodes quickly ended the era of the galena and cat's whisker detector.

Crystal set schematic showing similar set with 7 position switch and coil taps
(Source: The Radio Amateur's Hand Book by A. Frederick Collins, 1923)



The ten-position tap switch enabled good separation in tuning of the two local stations which are 370 KHz apart. At night I was able to also comfortably listen to a some distant stations with strong signals.
I also tried a very long wire antenna but found the volume to be about the same as with the 80 meter dipole.
Living the experience of a 1920s listener was the fun part. My hat is off in tribute to the quality work of the unknown builder of this very nice little set.

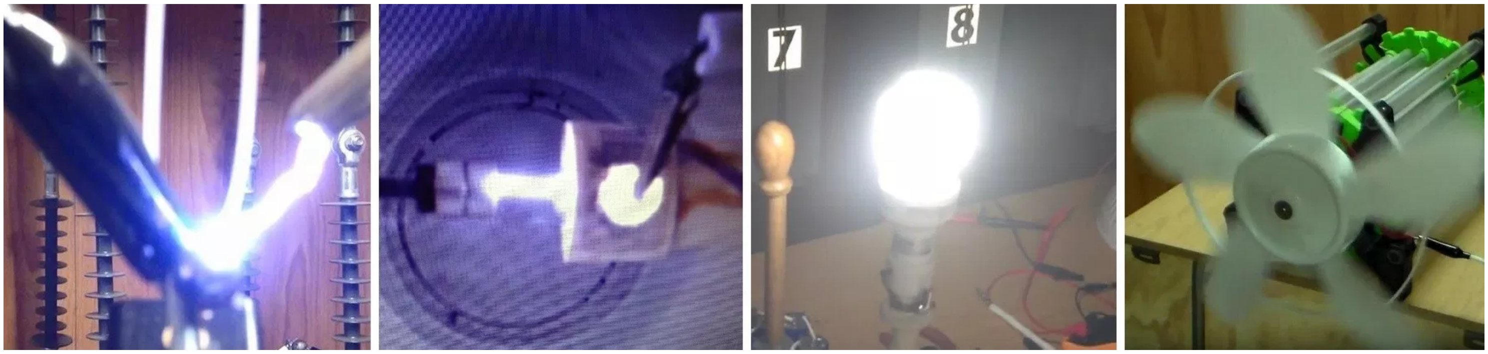
How
Ion Harvesting
generates
clean electricity
on Earth

Ion Harvesting Technology – the process of utilizing patented carbon nanomaterial to harvest the electric charge of naturally occurring ions in the atmosphere offers a way to produce clean supplemental high voltage electricity anywhere on Earth – day and night.



Experiments demonstrate that high voltage electricity harvested from airborne ions can power lights, motors or produce hydrogen & oxygen gas via water electrolysis or place a charge on lithium-iron (LiFePO4) batteries and be converted to 120VAC/60hZ ‘house style’ current. See ‘Concept Clips’ for videos.

Abstract of Economic Viability Report by Dr. Philip Metzger Planetary Scientist/Physicist PhD and NASA Kennedy Space Center Scientist/Engineer of the Year (blue text) Full Report is 16 pages

Analysis of the Economic Viability of Ion Power Generation

Philip Metzger, Ph.D.

Ion Power works as shown in the following diagram. The voltage source behind this power system is the Earth's global electric circuit. The Ion Collectors are positioned in the atmosphere to couple with the high voltage, pulling current to a lower voltage where it does electrical work through the electrical power grid. This report will first discuss how it works, then how it can be scaled up to industrial application, and then the economic viability of this power source.

How Ion Power Works

The Ion Power Group has performed tests at its facility in north Florida, successfully demonstrating the critical function of the technology application using their patented, carbon-based ion collector material, thereby achieving Technology Readiness Level 3 (TRL-3). In some of these tests, 400 ion collectors were

Click for Full Report

“Physics-based modeling shows that an (https://ionpowergroup.com/wp-content/uploads/2017/11/Economic-model-study-Rev-B-authored-by-Dr.-Phil-Metzger-PhD.pdf)electron cloud forms around the ion collector material, and this electron cloud increases conductivity of the air around the collector. This causes electrical current to flow, driven by the atmospheric voltage, so that power is generated at the ground. The rate of this current is governed by complex physics in the boundary layer of the collector material, doubtless because of its very high surface area. Ionization can occur on this collector at extremely low voltages because of the sharp, needle-like protrusions on its surface. This understanding of the physics suggests that power generation can be scaled as surface area times voltage. This was incorporated into a simulation of the solar cycle with random storms, and power generation of photovoltaics (PV) and Ion Power were simulated as feeding into a smart grid. Because Ion Power collects the most energy at complementary times compared to PV, the energy storage requirements on the smart grid is greatly reduced. This causes the cost of electricity also to be greatly reduced compared to photovoltaics alone, resulting in energy costs for the overall smart grid of about 8.25 cents per kWh, which is less expensive than any other energy source other than some wind farms (which are only slightly less expensive and have limited geographic applicability). This analysis uses extremely conservative assumptions, so actual energy costs may be much less. **The estimated value to the US economy is between $62 billion and $150 billion (annually)** with proportionately large value to the global economy. Thus, it is recommended that further development of this energy source begin immediately."

Galactic Cosmic Rays (GCRs) arriving from deep space bombard the Earth's atmosphere around-the-clock creating trillions of naturally occurring electrically charged ions throughout the atmosphere. Ion Power Group utilizes patented carbon nanomaterials to couple to some of these electrically charged airborne ions resulting in the harvesting of clean renewable high voltage electricity day and night.

Galactic Cosmic Rays arriving from deep space impact electrically neutral oxygen and nitrogen atoms in the Earth’s atmosphere producing a particle shower (or particle cascade) creating electrically charged ions in the atmosphere day and night.

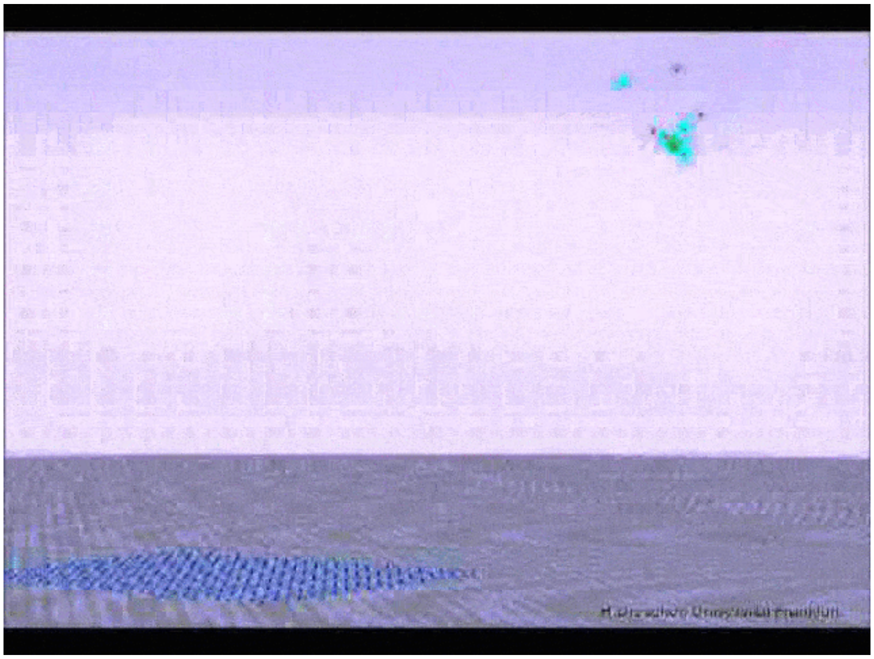
Very high-energy cosmic rays can generate huge showers of up to 10 billion secondary particles or more. The energies of the most energetic ultra-high-energy cosmic rays (UHECRs) have been observed to approach 3 × 1020 eV,[7] about 40 million times the energy of particles accelerated by the Large Hadron Collider. Each of the trillions of atmospheric ions generated throughout the Earth's atmosphere act as a charge carrier conveying a high voltage electric charge. The production of atmospheric ions is a natural process that occurs day and night across the entire Earth.



Watch the below video clip to see visual proof of cosmic rays bombarding the Earth's atmosphere – particularly the beginning and near the end of the clip.

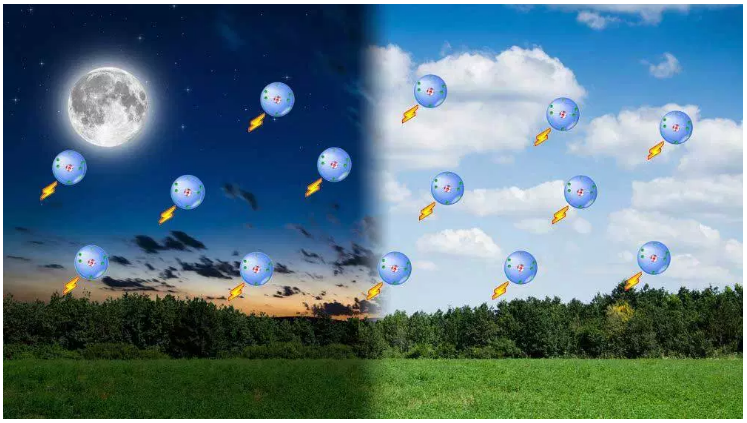
Atmospheric ions are produced by natural processes

Electrically charged ions are present in the Earth’s atmosphere day and night all around the world. Galactic Cosmic Rays arriving from deep space (which are actually microscopic particles traveling at relativistic speed) plus constant atmospheric electrical activity (thunderstorms) around the planet, plus Radon gas seeping from the Earth’s crust in certain geographic areas combine to replenish the supply of atmospheric ions. Atmospheric ions are a natural self-renewing energy resource that cannot be depleted.



Atmospheric ions are present day and night

In addition to constant GCR activity, at any moment about 2,000 thunderstorms are occurring around the Earth. On average, across the world there are 4,320,000 lightning discharges each 24 hour period (3000 per minute). This tremendous amount of high voltage electrical energy, together with GCRs bombarding the atmosphere and Radon gas seeping from the Earth's crust in certain areas, combine to actively replenish the supply of electrically charged atmospheric ions around the world.

Ion Harvesting Technology harvests electricity day and night and even during bad weather

Ion Power Group's ion collectors, when provided with adequate altitude, can harvest the electric charge of near-Earth ions to produce clean renewable high-voltage electricity day and night and during storms. Ion Harvesting Technology should not be confused with other techniques that attempt to capture lightning bolts or harvest manmade radio frequency (RF) energy.

Ion collectors can be composed of carbon/graphite/graphene, while not metallic, are electrically conductive, flexible and durable. Electric fields are known to coalesce at conductive points known as the “Corona Effect”. The solution of Poisson’s equation to determine electric field intensity around the collectors shows us that the highest electric fields will be around sharp points; the sharper the point, the greater the electric field. Ion collectors offer millions of microscopic electrically conductive points and protrusions which readily couple to the electric fields of near-Earth ions transferring high-voltage electricity from the atmospheric ions to the ion collectors.

$$\nabla^2 \varphi = -\frac{\rho}{\varepsilon}.$$

Ground based circuitry maintains the ion collector material at a voltage considerably lower than the surrounding atmospheric ions thereby employing the electrostatic attraction principle causing nearby ions to migrate to the ion collectors. High voltage wire connected to the ion collectors convey the harvested high voltage DC electricity to a storage medium or electrical load to produce work. Measurements have shown that ion collectors made of graphite are more efficient at harvesting electricity from airborne ions than all other tested metals. In some tests, by as much as 55x greater efficiency. Some of the tested metals include highly conductive silver, copper, and aluminum wire – aluminum spheres – copper and aluminum sheets.

The below graphs show voltage and current coupling characteristics comparing metal in one test (indicated as red and green) to carbon/graphite (indicated as purple).

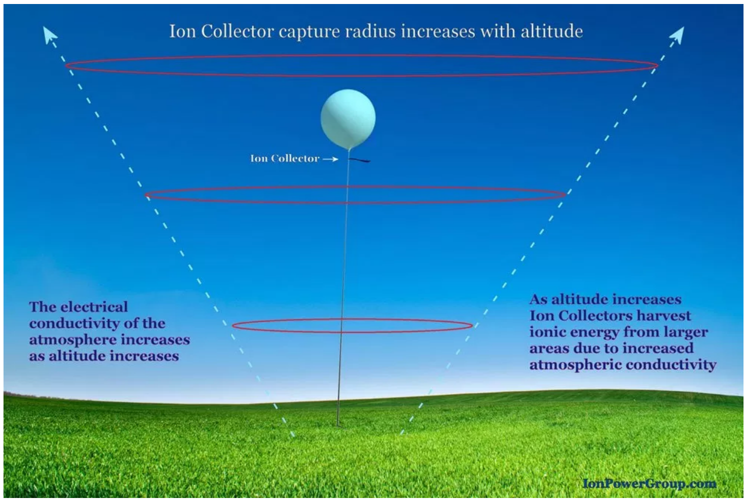
Electricity is produced by providing sufficient altitude to the ultra lightweight ion collector through the use of long-duration aerial platforms including tethered balloon, kite or tower. Atmospheric voltage increases at the rate of approximately 90-150vdc per meter of altitude above ground level or sea level and many orders of magnitude greater during disturbed weather. Experiments have demonstrated that the electric charge of atmospheric ions can be harvested by ion collectors and stored in capacitor banks, super-capacitors, lithium-iron (LiFePO4) batteries, directed to a water electrolyzer to produce hydrogen and oxygen gas or converted to 120VAC/60hZ ‘house style’ output power. An equally important role of atmospheric ions is that ions cause the atmosphere to be electrically conductive allowing ion collectors to harvest more electricity during disturbed weather or increased altitude above ground level. The atmosphere’s electrical conductivity increases with altitude. For example, when a storm or active cloud formation is nearby, the harvested DC power can skyrocket many orders of magnitude by reason of the conductivity of the atmosphere. This is often referred to as a peak ion period or disturbed weather.



Ion Collector capture radius increases with altitude
Ion Collector →
The electrical conductivity of the atmosphere increases as altitude increases
As altitude increases Ion Collectors harvest ionic energy from larger areas due to increased atmospheric conductivity
IonPowerGroup.com

Atmospheric voltage increases about 90-150vdc per meter of altitude

Additionally, the Triboelectric Effect plays a role in how much electricity is harvested. Geographic areas with Radon gas can tend to have greater ionic airborne densities closer to the ground due to the gas leaking up from the Earth. To a degree not yet defined, man-made air pollution can also raise the level of airborne ion densities. Cities with polluted air may prove to enjoy an extra benefit from ion harvesting. Galactic Cosmic Rays (which are actually particles) travel at enormous speed through outer space and impact the Earth’s atmosphere. Many of the GCRs are attenuated by the atmosphere, but some are energetic enough to penetrate into the atmosphere where they can impact electrically neutral oxygen and nitrogen atoms with such intense kinetic energy that a particle cascade is produced that creates electrically imbalanced atoms (ions) all along a downward path allowing some of the ions to cascade nearer to the Earth’s surface. The imbalanced atoms (ions) created all along the particle cascade can extend down nearer to the Earth’s surface where ion collectors harvest the electrical field potential of the ions to receive and store usable high voltage DC electricity. Since the ions effectively cause the air to be electrically conductive, they create an electrical path for storms occurring in other locations of the globe to contribute to the Earth's overall ambient atmospheric electrical voltage. Ion Power Group's remote test site (est. 2005) located on a 300 acre Florida pasture, uses tall poles (130 feet) to elevate ion collectors for research purposes. A wire conveys the harvested energy down to the remote research lab. The act of harvesting the electric charge from atmospheric ions harmlessly reverts the ions back to their original state of neutral atoms. The former ions, now neutral atoms, are once again free to migrate through the atmosphere – available to be converted back into electrically charged ions by natural processes. Ion harvesting results in the generation of clean, natural, renewable energy that will not pollute Earth.

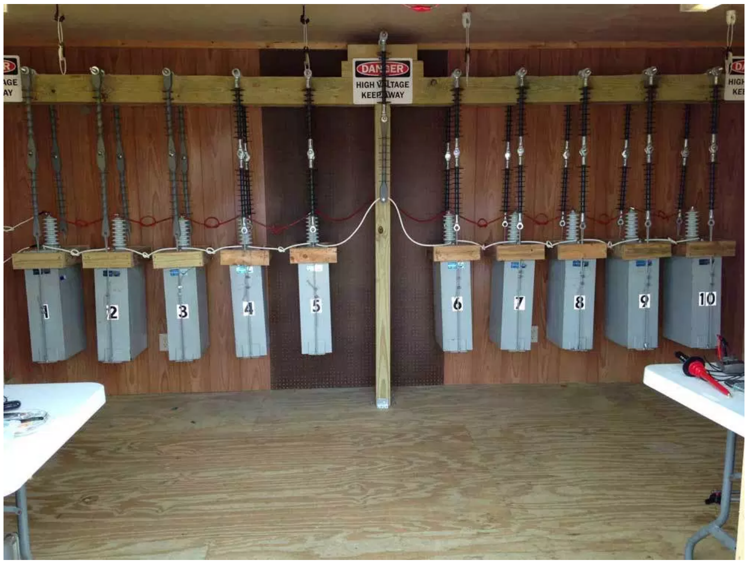
The peak electrical power generated in real-time by Ion Power Group's proof-of-concept prototype during peak ion periods with the ion collectors at 130 feet above ground level is 1,236 watts (1.236kW). Derived from 41,200 volts @ 30.ma directly measured through a 1000x probe during peak ion periods.



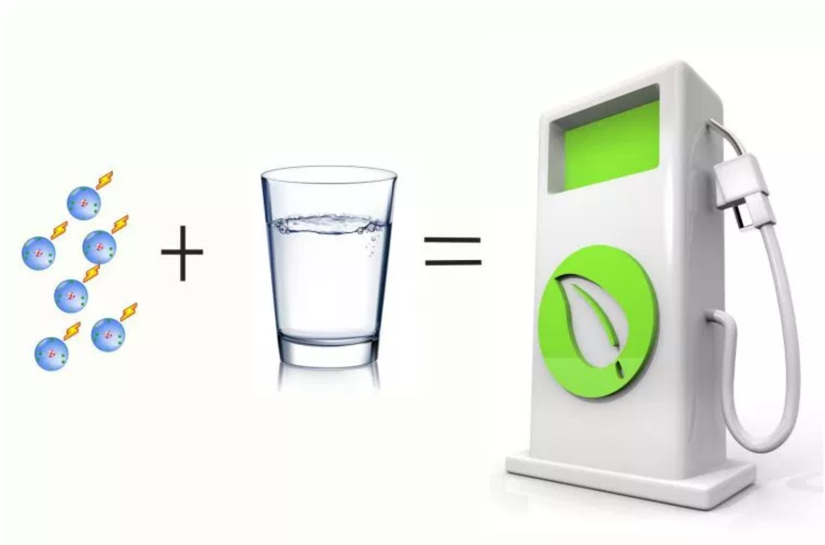
(https://i0.wp.com/ionpowergroup.com/wp-content/uploads/2016/09/Capacitor-Bank-Opti.jpg?ssl=1)

Bank of 10 General Electric high voltage capacitors at the Florida research and development test site

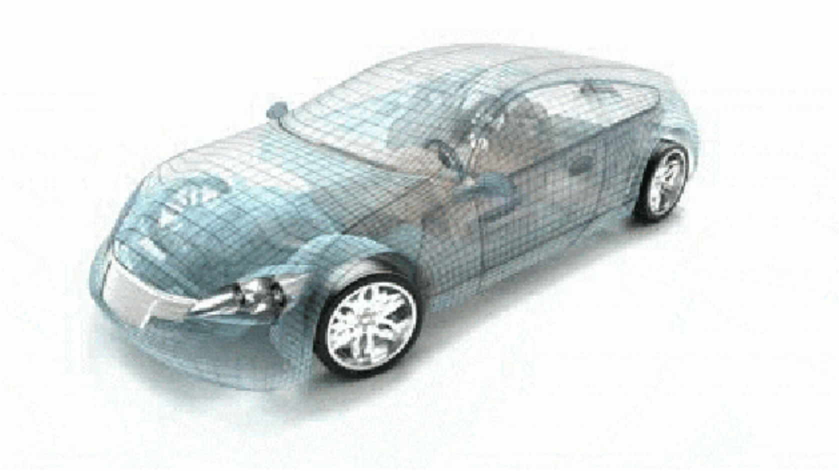
The above General Electric capacitor bank, rated at 75.uf, has repeatedly been charged up to >29,000.vdc (29.kV) equating to >31,000 Joules (31.kJ) of energy by harvesting the electric charge of airborne ions in real-time during peak ion periods with the ion collectors at 130 feet above ground level. The stored energy has been used for demonstrations including powering 32 feet of florescent lights, motors and producing hydrogen gas from water.

Hydrogen Gas produced from Water: Ion Power Group has demonstrated that it is possible to harvest atmospheric ions to generate electricity that can be utilized in electrolysis to produce hydrogen gas and oxygen gas from water (in proof-of-concept quantities so far). Hydrogen gas is used by next generation, non-polluting, hydrogen powered cars produced by worldwide automobile manufacturers including the world’s largest automaker – Toyota. Ion Power Group has been awarded a patent for a novel approach to producing hydrogen gas from water utilizing power obtained from ion harvesting.

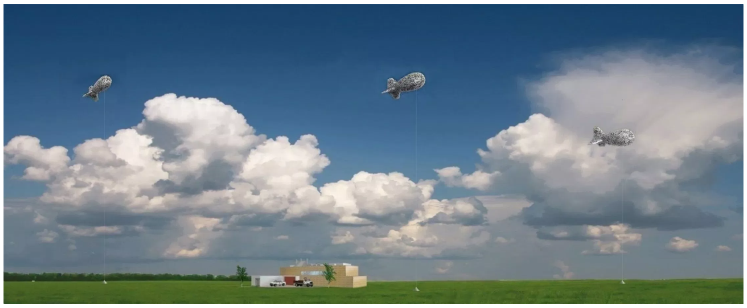
Electricity harvested from Airborne Ions + Water = Hydrogen Gas



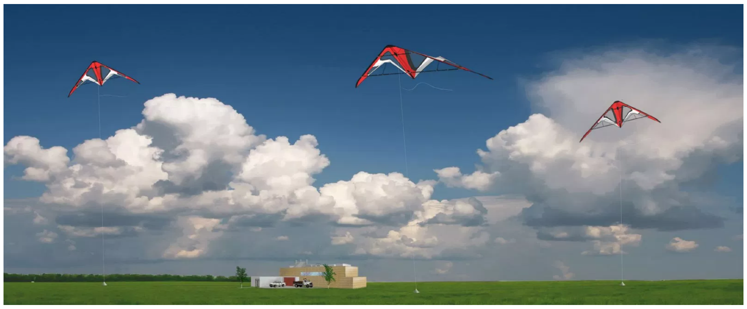
Ion Power Group has been awarded patents for installing ion collectors on automobiles to generate electricity including through the Triboelectric Effect. Preliminary field tests in which a truck, equipped with Ion Collectors, demonstrated that the concept can generate >500 volts when the vehicle is in motion. Initial tests are encouraging, however, further development is required in order to realize automobiles that generate their own supplemental electricity (or onboard hydrogen gas from water) through use of Ion Collectors.



Illustrations (below) of proposed experimental ion power plants using long-duration aerostats (aerostats or balloons) or kites or towers to provide altitude to the ion collectors to harvest ions for electricity, day and night. Future Ion Harvesting Technology embodiments that use long-duration aerostats (balloons) to provide great altitude to ion collectors offer a theoretical energy producing duty-cycle approaching 99%.



Tethered aerostats covered with patented carbon/graphite nanofiber to harvest clean electricity day and night from atmospheric ions. The harvested electricity is conveyed down the conductive tether for use on the ground.



Kites used to provide altitude to patented ‘strip’ carbon/graphite nanofiber to harvest clean electricity day and night from atmospheric ions. The harvested electricity is conveyed down the conductive tether for use on the ground.

Long duration weather balloons used to provide altitude to ion collectors made of patented carbon/graphite nanofiber to harvest clean electricity day and night from atmospheric ions. The harvested electricity is conveyed down the conductive tether for use on the ground.

Theoretical vs Real-World:

There are a number of technical reports and peer reviewed journal articles available for viewing on the internet that do an excellent job of characterizing the Earth’s Electric Circuit addressing fair weather (the load of the circuit) as well as perturbed conditions (the generator part). These reports tend to model the Earth’s Fair Weather Circuit as a ‘whole’ averaging the energy produced by thousands of storms over the entire atmosphere. One might conclude from such reports that the atmosphere offers a maximum of 2 pA/m2 of electrical current. Ion Power Group has oftentimes measured significantly greater power during peak ion periods – many watts of harvested power – as great as 1,236 watts (41,200vdc @ 30ma) with ion collectors at 130 feet altitude. What accounts for the very wide discrepancy between theoretical models presented by some reports available on the internet and Ion Power Group’s real-world measurements? **Answer:** Localized disturbed weather can greatly increase the electrical component of the *local* atmosphere thereby significantly increasing the level of electricity available to ion harvesting by many orders of magnitude. In addition, for estimating the available power, the voltage increase with altitude, air conductivity (e.g. with respect to Radon emissions from the surface), and characteristics of the instrumentation (conductivity of the material, insulation) need to be considered. Because of these complexities, there are hardly any realistic studies or even measurements on the available power locally outside of research conducted by Ion Power Group. Also, the total power in the electric circuit is still an open research question. Most researchers who have published reports about the Fair Weather Circuit intentionally do not focus on the local effects of disturbed weather or Radon gas components. With regard to harvesting electricity from the atmosphere, the absence of modeling the beneficial effect of localized disturbed weather and the effects of Radon gas may lead readers to a conclusion that drastically underestimates the *actual* electrical power available to be harvested during localized disturbed weather. During real-world testing, Ion Power Group has repeatedly demonstrated that localized disturbed weather greatly increases the electrical power output of ion harvesting technology, many thousands of times greater than 2 pA/m2 when using carbon/graphite nanomaterials in the harvesting process. The solution to increasing electrical power is to provide greater altitude to the carbon nanomaterial ion collector, via long duration tethered balloon, thereby increasing the harvested voltage. The electrical conductivity and voltage of the atmosphere increases with altitude by approximately 90-150vdc per meter, therefore, the effective capture-area increases as the Ion Collector is raised higher in altitude (see the above image titled “Ion Collector Capture Radius Increases with Altitude”). Voltage (and sometimes current, depending e.g. on orography) have been observed to increase as an ion collector is raised in altitude. However, assuming a situation in which the atmospheric current stays constant while voltage increases (due to the ion collector being raised to a higher altitude) the result is a net power increase as shown in this formula.

P=VxI. Therefore, if I is constant, as V increases, P increases proportionately

Ion Harvesting Technology addresses the problem of low atmospheric current during fair weather conditions by increasing the altitude of ion collectors thereby increasing overall harvested power. It is noteworthy that none of the reports presently available via the internet address the harnessing of atmospheric electricity for power production based on using more efficient carbon nanomaterials such as Graphite and Graphene. Therefore, present reports do not reflect the most recent advancements in technology for harvesting atmospheric electricity. For the reasons stated herein, previous reports available prior to Ion Power Group’s research (while most are very good when read in context) should not be considered an accurate representation of the *actual* electrical power available to advanced Ion Harvesting Technology because the reports do not model available power based on the complex current flow considering the local atmospheric conductivity, potential distribution, and how utilizing carbon (https://ionpowergroup.com/wp-content/uploads/2018/04/Aerostat-Deployed-v2.0-with-output-cable-v2.5.jpg) nanomaterials (https://ionpowergroup.com/wp-content/uploads/2018/03/Aerostat-High-Wind-Design-v3.0.jpg) such (https://ionpowergroup.com/wp-content/uploads/2018/03/Tether-images-with-border-v3.0-100.jpg) as (https://ionpowergroup.com/wp-content/uploads/2018/03/Aerostats-WWII-montauge-v1.0.jpg) Graphite (https://ionpowergroup.com/wp-content/uploads/2018/04/Trailer-Cost-per-Watt.jpg) and Graphene alter (https://ionpowergroup.com/wp-content/uploads/2018/03/Ion-Harvesting-Power-Estimator-v6.0.jpg) the (https://ionpowergroup.com/wp-content/uploads/2018/02/Electrical-Power-Differential-Estimator-v5.0.jpg) process.

How Ion Harvesting can generate clean electricity on Mars

/>

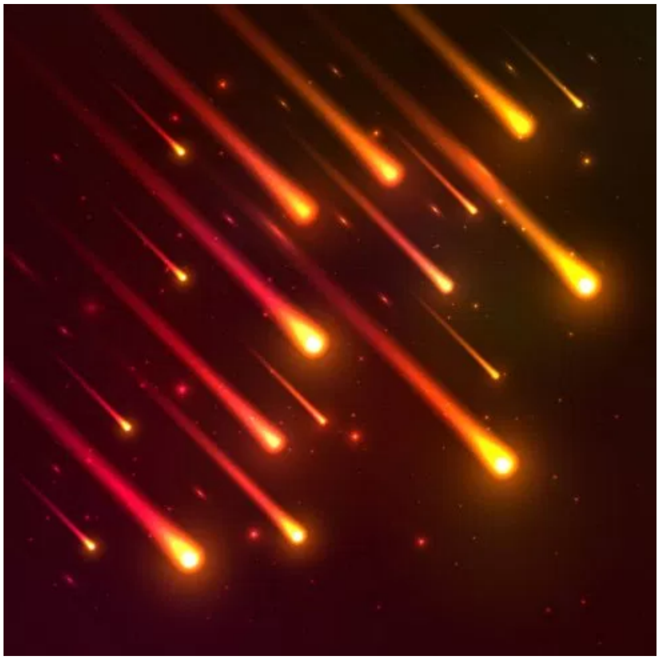
DOCUMENTARY REPORT ABOUT IONPOWERGROUP COM V1 5 fi...

Highly energetic **G**alactic **C**osmic **R**ays (GCRs) arriving from deep space impact Mars' atmosphere on a consistent basis creating electrically charged ions throughout the atmosphere.

Carbon/graphite nanomaterials have been shown to be effective at harvesting electricity from atmospheric ions on Earth. Likewise, it is anticipated that carbon nanomaterials elevated into the Martian atmosphere can also harvest electricity from Mars' ion-rich atmosphere day and night and particularly during dust storms.

On Earth, experiments have demonstrated that high voltage electricity harvested from airborne ions can power lights, motors or produce hydrogen & oxygen gas via water electrolysis or place a charge on lithium-iron (LiFePO4) batteries and be converted to 120VAC/60hZ 'house style' current. Mars has an ion-rich atmosphere believed to be even more advantageous for Ion Harvesting Technology. See 'Concept Clips' for videos.

GCRs penetrate deeply into Mars' thin atmosphere as depicted below.



On February 10th 2016, Senior Scientist of Atmospheric Physics Dr. Andreas J .G. Baumgaertner PhD published a technical report titled ‘Power to Mars’. To read the report, click the below Power To Mars report image or read it on Zenodo by clicking here (https://zenodo.org/record/1045600#.Wgm41Bte6Uk). The report recommends that ion harvesting technology be combined with solar panels to provide reliable power day and night for future Mars missions. With a theoretical power generation duty-cycle approaching 99% ion harvesting technology is designed to continue to produce electricity during conditions that cause solar panels to fail such as nighttime and dust storms.

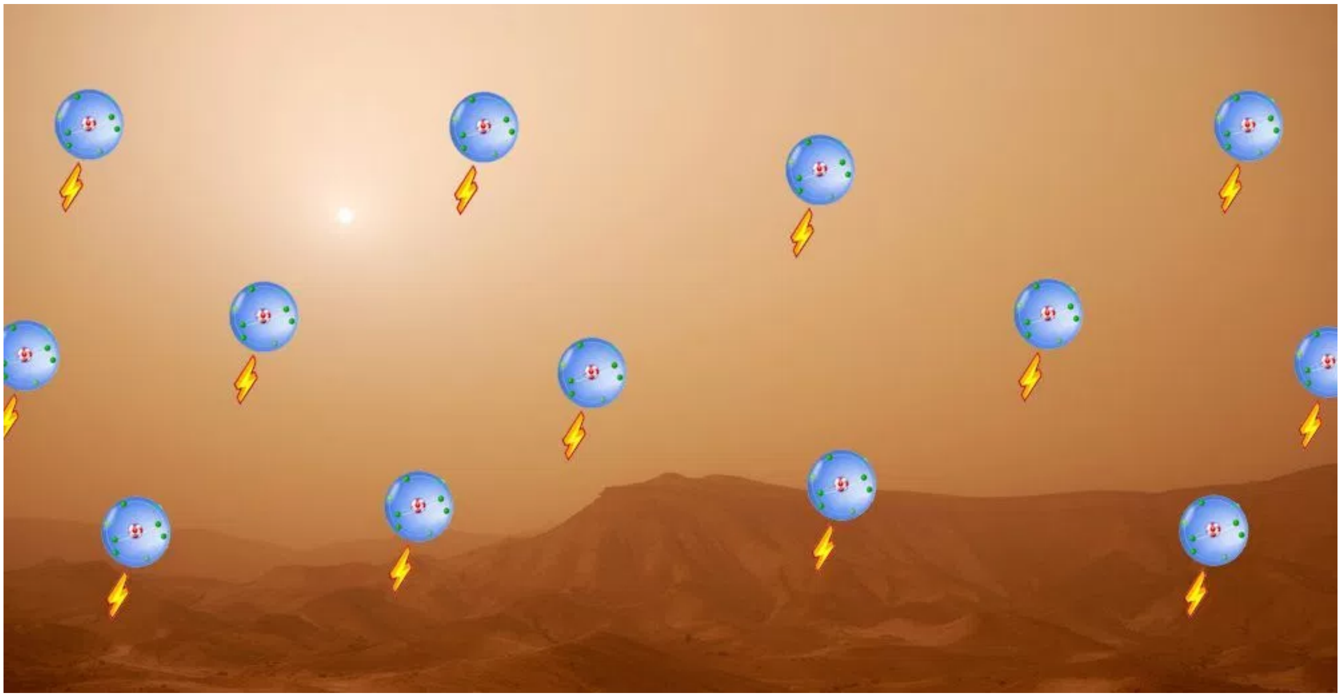
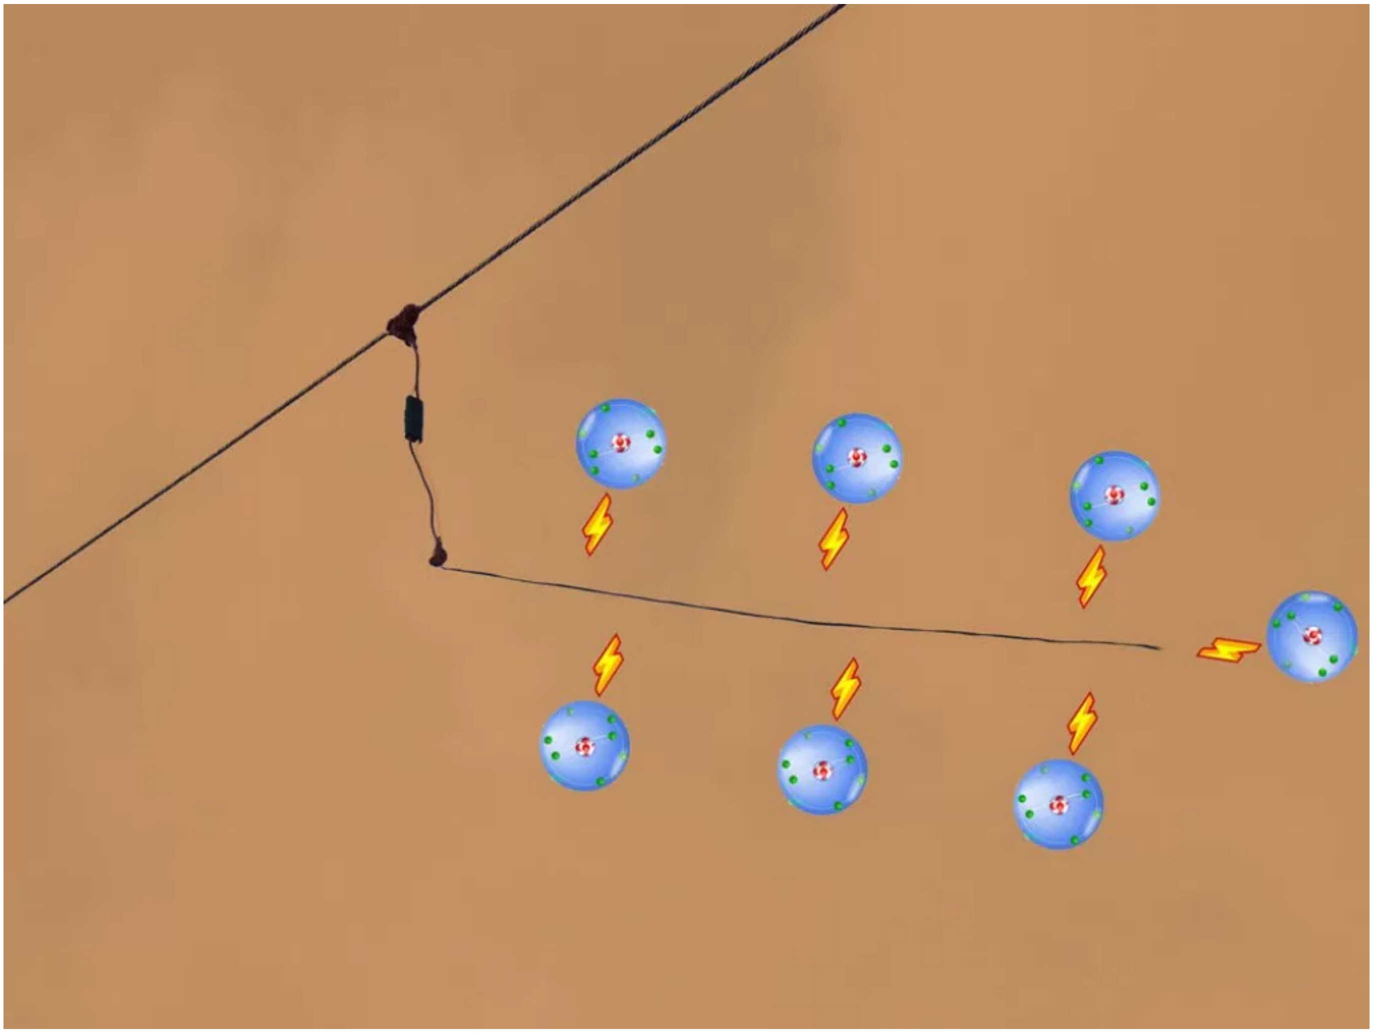
Dust storms occurring on Mars generate strong electrical fields that propagate throughout the Martian atmosphere conveyed by the ions constantly present in the atmosphere. Dust storms can cover large regions of the planet blotting out the sun and can persist for days or weeks. Because the ion-filled Martian atmosphere is electrically conductive, electricity generated by remote dust storms elsewhere on the planet is permitted to propagate throughout the Martian atmosphere. NASA Scientist, Michael Smith, who works at the NASA Goddard Space Flight Center told Space.com "***The dust is electrostatic, like foam peanuts.*"** In an interview with NewScientist.com, Brian Jackson with the Physics Department at Boise State University says **"*It's possible that all of the dust grains clattering together in these storms could produce a lot of electricity…*"** interview seen here (https://www.newscientist.com/article/2143217-marss-surface-hosts-millions-of-towering-dust-devils-every-day/).



Ion Power Group’s ion collectors, elevated in the Martian atmosphere by tall poles or specially designed aerial platforms (balloons), are designed to harvest the electric charge conveyed by near-Mars ions to produce clean renewable high-voltage electricity day and night and during dust storms as depicted below.



Ion collectors composed of Graphite and/or Graphene, while not metalic, are electrically conductive, flexible and durable. Electric fields are attracted to conductive points, known as the 'Corona Effect'. Ion collectors offer millions of microscopic electrically conductive points and protrusions which readily couple to the electric fields of nearby ions transferring high voltage electricity from the atmospheric ions to the ion collectors. Measurements have shown that ion collectors made of graphite are more efficient at harvesting electricity from airborne ions than tested metals. In some tests, by as much as 55x greater efficiency. Some of the tested metals include highly conductive silver, copper, and aluminum wire – aluminum spheres – copper and aluminum sheets.

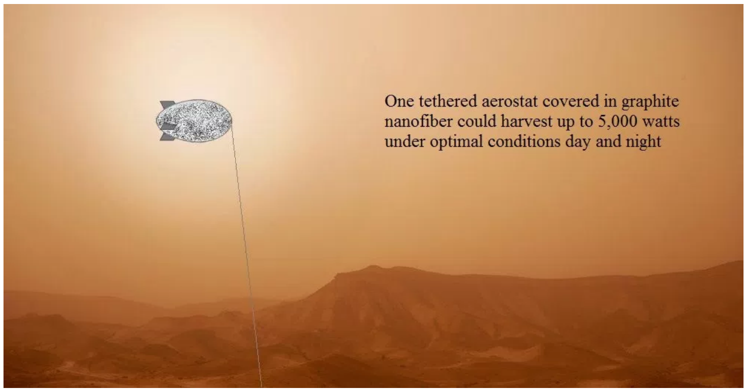
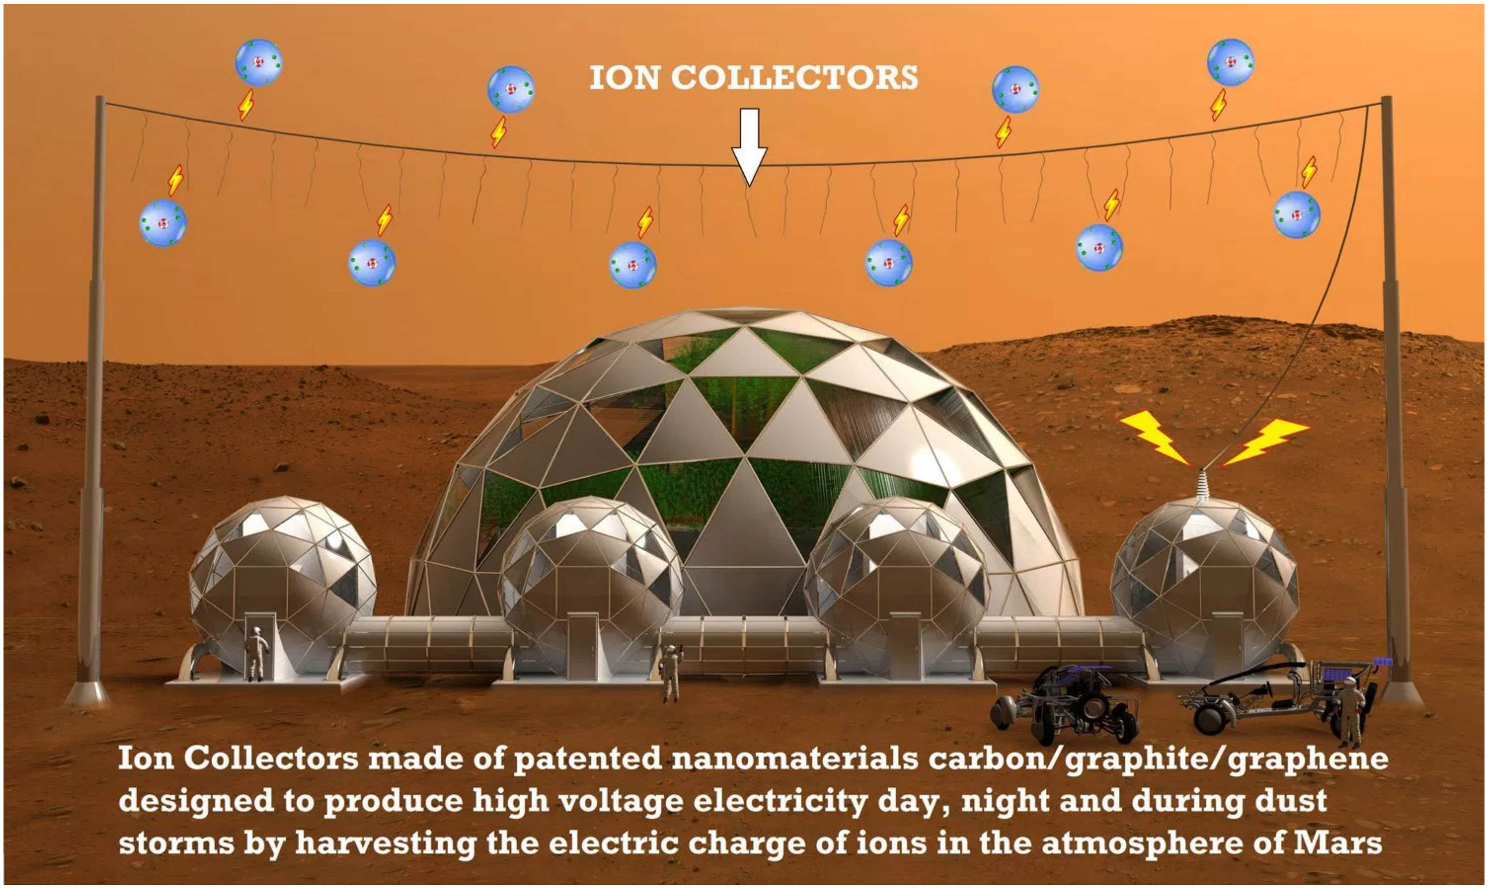
Ion Power Group's internationally patented ion collectors, elevated between two poles in the below depiction, are specially designed to couple to the energetic electrically charged ions in the Martian atmosphere. Ion collectors are designed to harvest the high voltage DC electric charge from naturally occurring atmospheric ions day and night and during dust storms and are not dependent on sun or wind. Ground based circuitry has been designed to maintain the ion collector material at a voltage considerably lower than the surrounding atmospheric ions thereby employing the electrostatic attraction principle causing nearby ions to migrate to the ion collectors. Wires will convey the harvested electricity to the base camp where it is routed to a storage medium (such as super capacitors, graphene batteries, lithium-ion batteries, hydrogen gas fuel cells) to be used for life support, light, heat, the production of oxygen for breathing and rocket fuel (hydrogen) from Martian water, communications, fisheries, agriculture and transportation.



One tethered aerostat covered in graphite
nanofiber could harvest up to 5,000 watts
under optimal conditions day and night

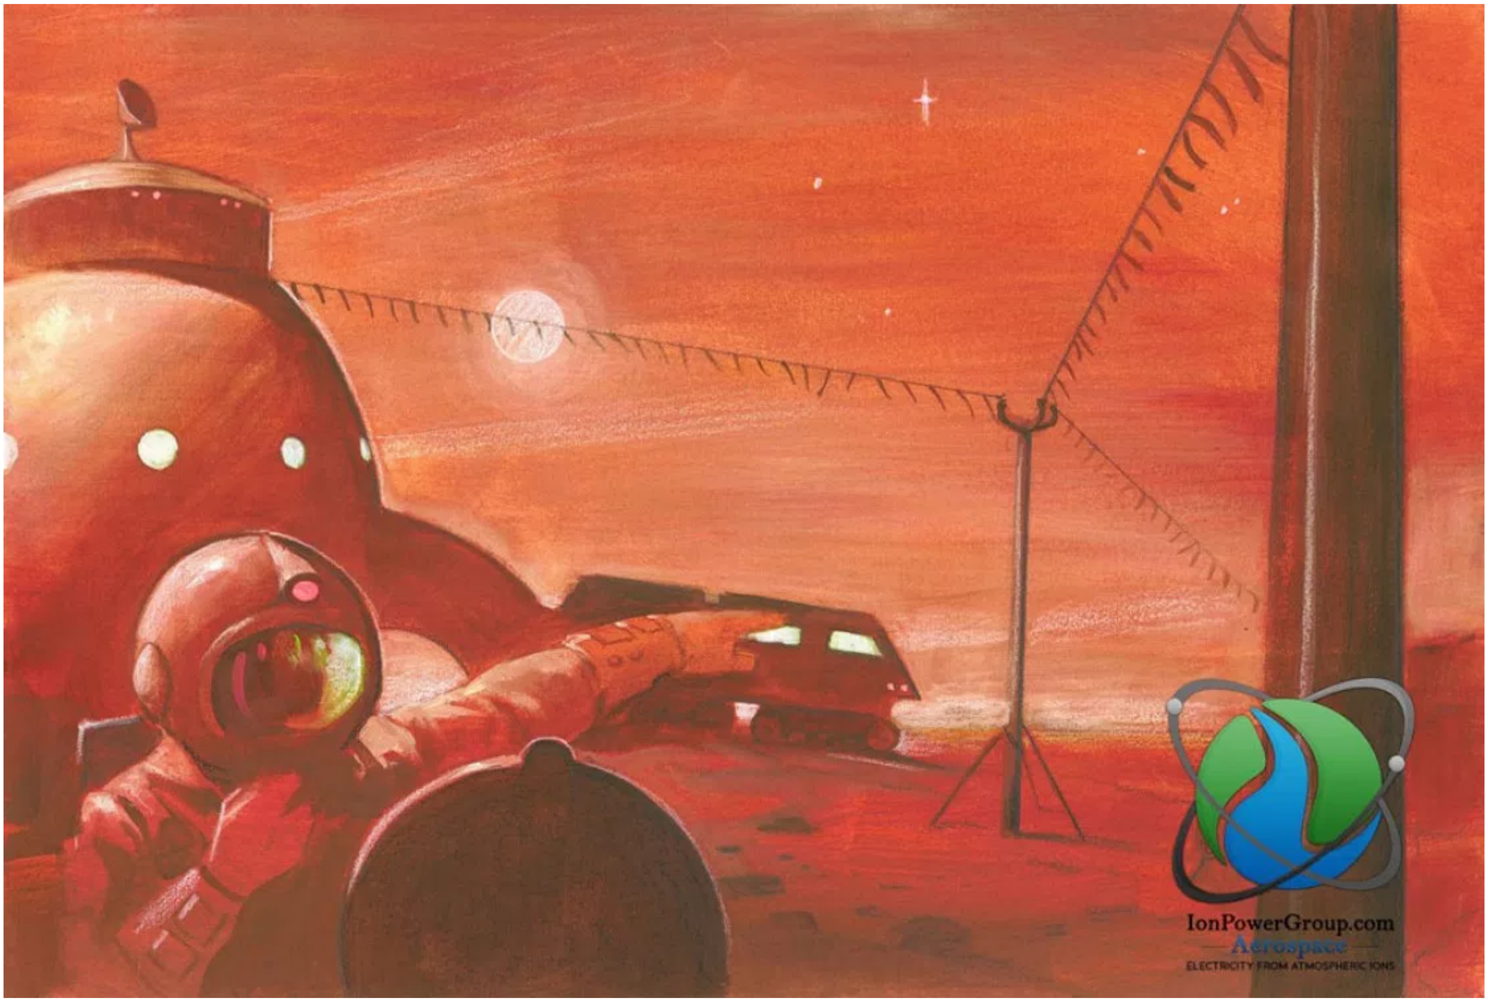
Artists rendering of a tethered aerostat providing altitude for graphite nanofibers to harvest electricity from ions in the Martian atmosphere day and night. The harvested electricity is conveyed down the conductive tether for use on the ground.

Below is a genuine image of Mars' surface. Superimposed is an artist's image of Ion Power Group's ion collectors (thin black material dangling between the two poles) providing electrical power to a conceptual Mars base camp similar to those planned by governments, private and corporate aerospace organizations. Long duration aerial platforms (tethered balloons) may also be used to provide altitude to lightweight ion collectors.



ION COLLECTORS
Ion Collectors made of patented nanomaterials carbon/graphite/graphene designed to produce high voltage electricity day, night and during dust storms by harvesting the electric charge of ions in the atmosphere of Mars

"Solar power… cannot be used at night and during dust storms. It has been shown (in the Power to Mars technical report) that ion power and solar power can be combined to provide a reliable and safe power generation concept." **PhD Atmospheric Physicist and Senior Scientist with the German Aerospace Center, Dr. Andreas J .G. Baumgaertner**



The conditions on Mars including a weak magnetic field, frequent dust storms around the planet and constant bombardment of the Martian atmosphere by GCRs provide an ideal electrical environment for Ion Power Group technology to harvest the electric charge of naturally occurring atmospheric ions to produce reliable, environmentally friendly, electrical power without reliance on sunlight, wind, nuclear or fossil fuels. The highly ionized Martian atmosphere will provide an extremely fertile electrical environment for Ion Power Group's technology to generate clean renewable pollution-free electrical energy day and night and during dust storms. The ability of ion harvesting to generate electricity day/night/dust storms will prove valuable to power robots, rovers, drones, vehicles, living quarters, lights, communications, entertainment equipment, heat to melt Martian ice for drinking, trenchers for extracting water from soil, water for agriculture and fisheries as well as producing hydrogen gas to use for rocket fuel and oxygen for breathing through electrolysis of Martian water.

Nearly 100 countries have some level of space program. A growing number of governments, as well as many private and corporate organizations, are developing plans to send robots and hardware to be followed by people to colonize Mars in the foreseeable future. All of these campaigns will require a reliable source of electrical power on the surface of Mars.

Additional information regarding Ion Harvesting Technology’s Principle-of-Operation can be found on the page titled “How it works on Earth. (/how-it-works-on-earth/)

The survival of humans on Mars requires that the settlers have access to reliable electrical power production, day and night and during the lengthy dust-storms known to occur on Mars. Ion Power Group believes that ion harvesting is the long term solution.

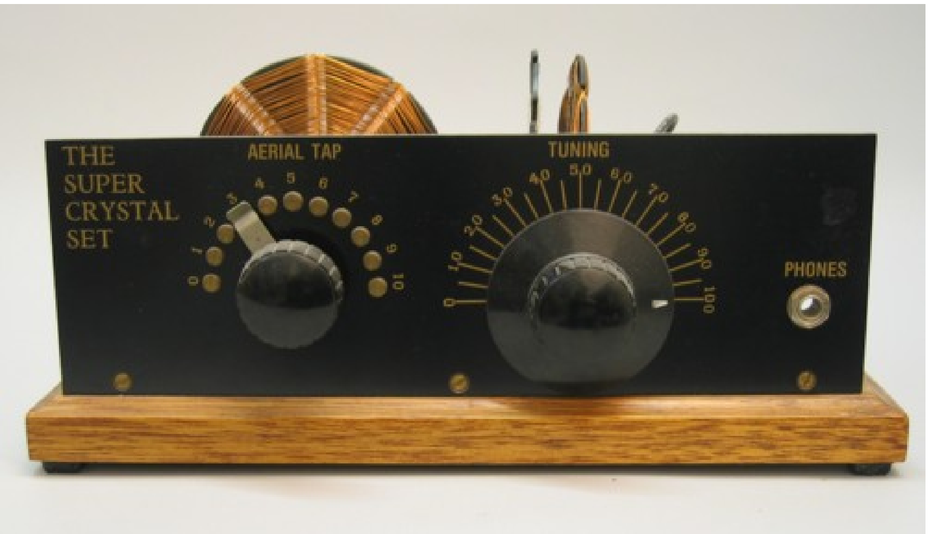
Crystal Set



Many years ago I purchased a crystal set kit from Orpheus Radio in Ballarat. The design of the set was based on a 1920's naval radio and featured high-Q spider-web inductors, a variometer, mica capacitors and a rotary inductance selector switch. It is one of the best DX crystal sets I have ever owned. The selectivity and sensitivity are excellent and with this set I have been able to receive many stations from around Australia and south-east Asia. Unfortunately, Orpheus Radio doesn't seem to exist any more so for the crystal set enthusiast wanting to build this excellent radio apparatus, here is a description of that set. For the purist, the germanium diode can be replaced with a cat's whisker detector to produce a totally authentic piece.

Headphones

Before the construction of a crystal set is contemplated, a pair of high quality high-impedance headphones should be obtained. The performance of the crystal set is highly dependant upon the quality of the phones. It is possible (and I have done so) to modify a set of standard 600 ohm headphones to produce an excellent pair of high-impedance phones. The modifications include complete disassembly of the phones and tediously re-winding the coils. This is not a job for the feint-hearted but if your sense of adventure extends this far then the results can be very satisfying.

Schematic of the crystal set

Circuit Description

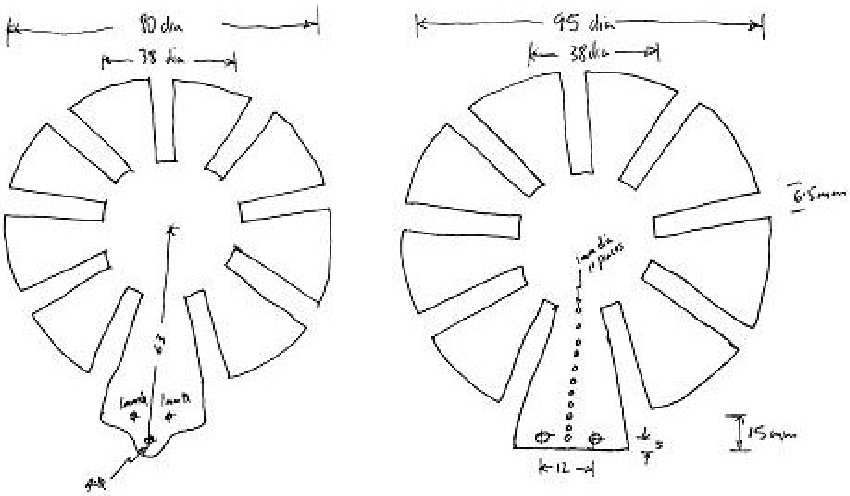
The crystal set incorporates an aerial tuning circuit that is quite separate from the main tuning. Altering the aerial switch selects an appropriate tap on L1 to bring the aerial circuit in to tune. The 435pF aerial capacitor C1 will enable the circuit to tune a long aerial. In some cases, it may necessary to reduce the value of this capacitor to enable a very long aerial to be brought into tune.

Following the aerial circuit is the variometer coil L2, used to control the amount of RF coupling to the main tuned circuit. As L2 is pivoted away from the tuning coil L3, the amount of interaction (or mutual inductance) between these coils is reduced. In this way the amount of energy drawn from the aerial circuit is minimized, maintaining sharp tuning of the set.

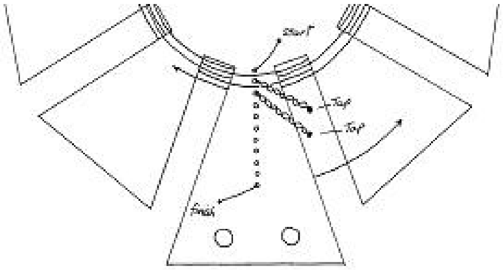
The main tuning circuit consists of L3 and the tuning capacitor C2. This circuit is energised via the aforementioned variometer and some of its energy is drawn off to feed the detector circuit consisting of D1 and C3. As with the aerial circuit, it is important that the energy drawn from the tuned circuit is minimised. This is achieved by the tap selection on L3. For a given detector arrangement, an optimum tap is selected using the flying lead and alligator clip.

Construction

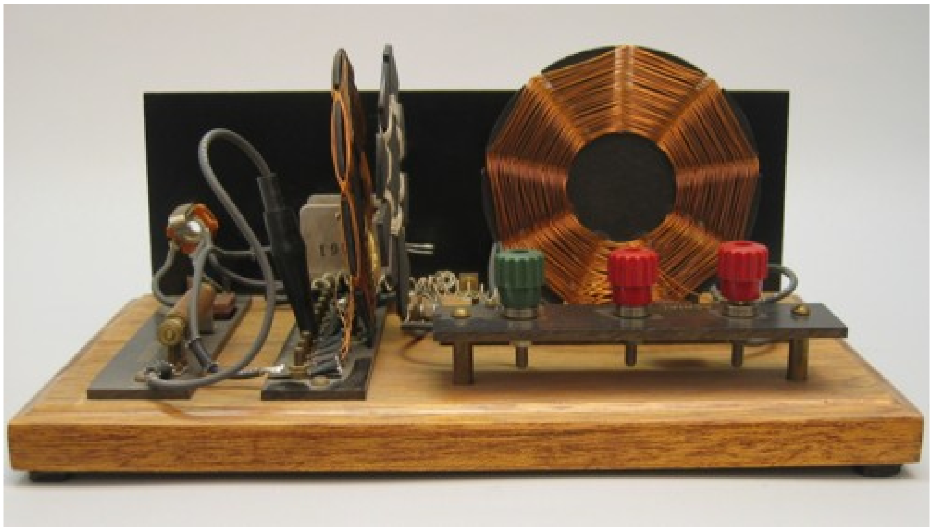
The coils are wound in the spider-web style and due to the low inter-winding capacitance of this winding arrangement, a coil of very high Q results. The details of the former and winding format are illustrated in the following sketches.



Spider-web coil formers, variometer on the left and aerial and tuning coils on the right



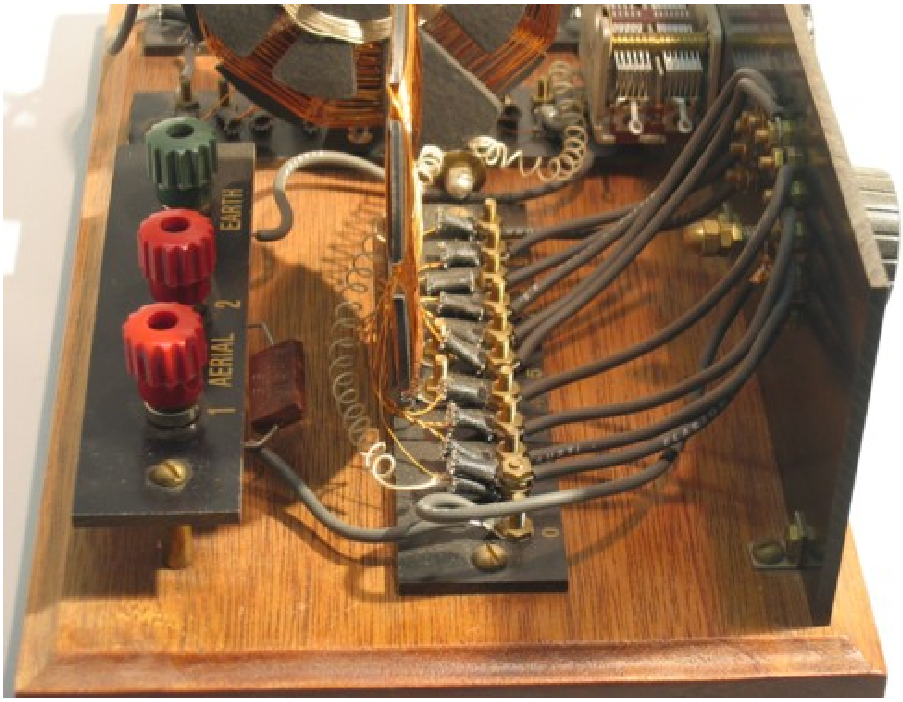
Coil winding details - aerial loading coil (L1) and tuning coil (L3) - 80 turns of 26g B&S enamelled wire with a tap every 8 turns. variometer coil (L2) - 14 turns



Rear view of the crystal set

Aerial coil taps

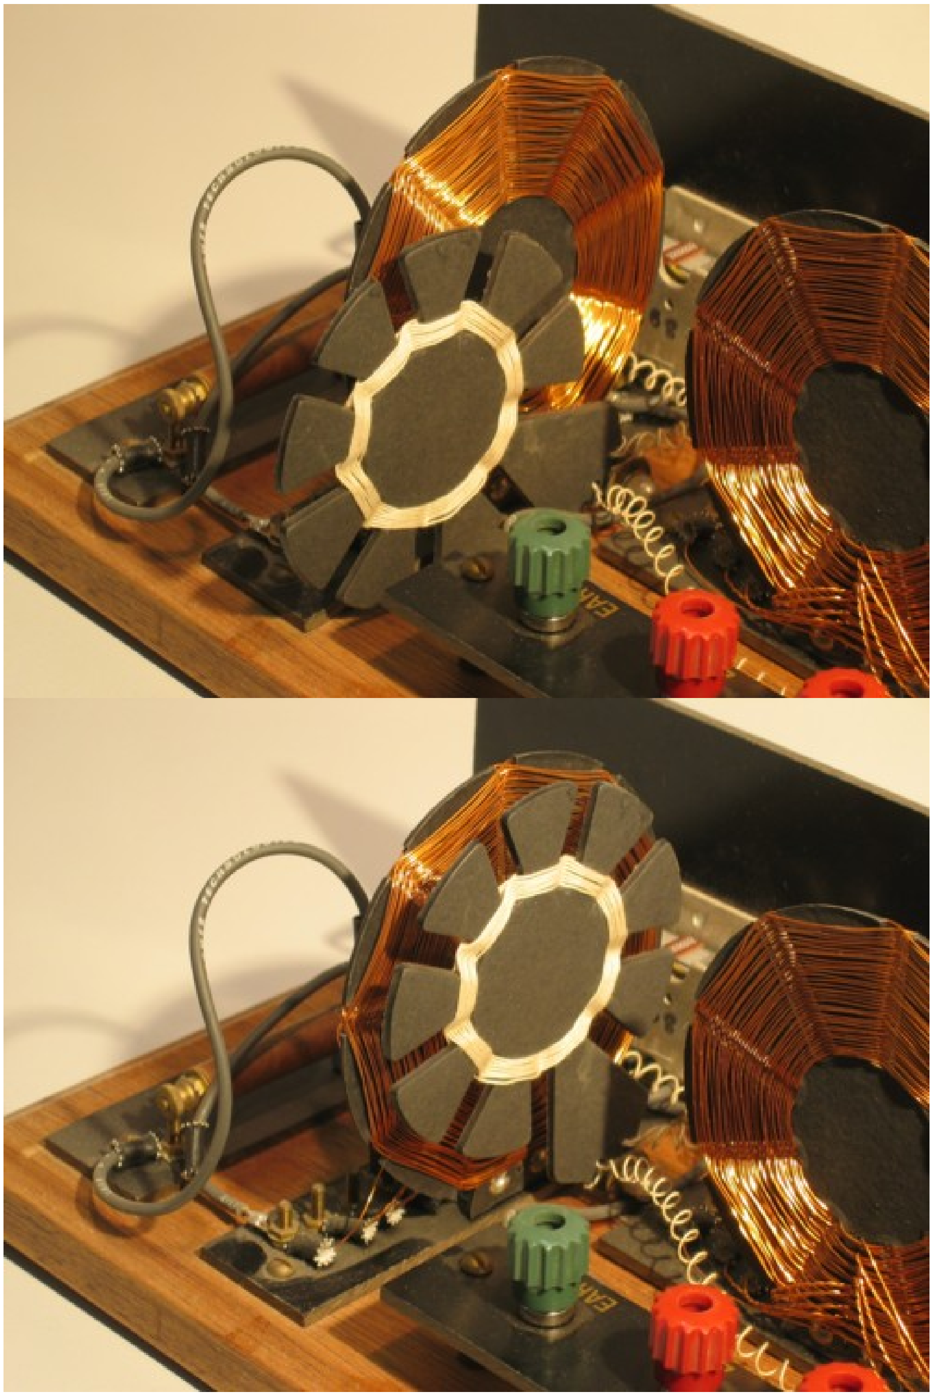
The coupling coil (variometer) is pivoted at its mounting bracket to allow the amount of RF coupling to be adjusted by the operator. For best selectivity, it should be adjusted for the least amount of coupling possible. Increased coupling will provide increased volume but the selectivity of the set will deteriorate markedly.



Aerial coil taps

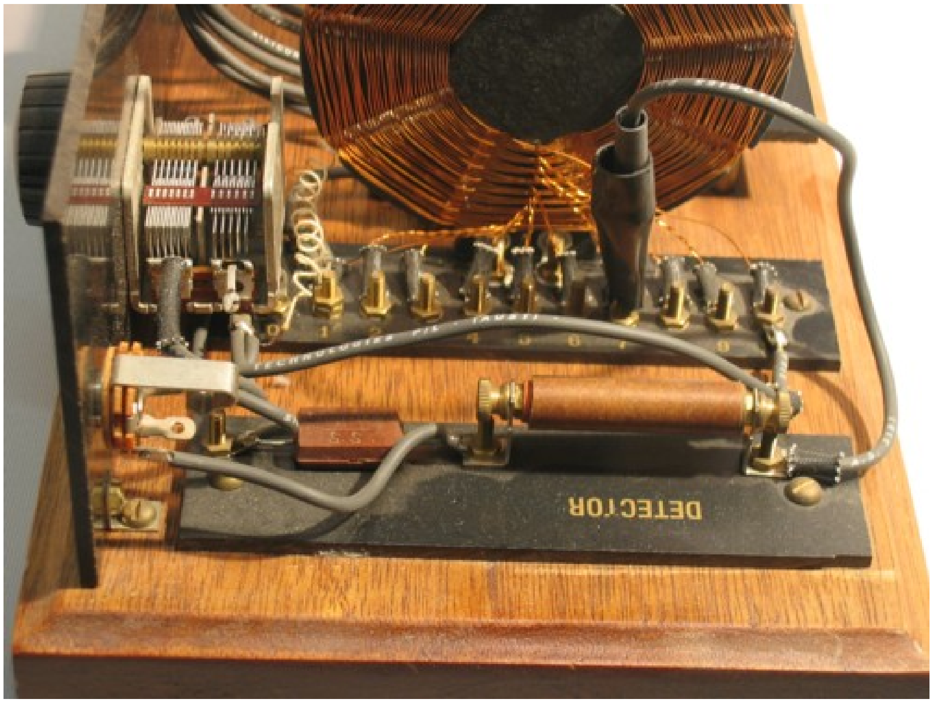
Operation

The set requires a substantial aerial and earth system for best performance. It can be a little tricky to operate as several separate tuning operations are required. One operation selects the appropriate station by turning the tuning knob and the other tunes the aerial circuit by adjusting the aerial taps. Additionally, the variometer and detector tap will need to be adjusted and the correct aerial terminal selected (terminal 1 for short aerials and 2 for long ones). All of this makes for an interesting and challenging pastime. A log book is useful for recording the various adjustments so that an interesting station can be revisited at a later date.



The variometer set for minimum and maximum coupling

To operate the set, connect the aerial and earth, plug in the high-impedance headphones, set the aerial tap to 0 and set the variometer for maximum coupling. It should now be possible to find a station using the tuning control (C2). Once a station is found, reduce the variometer coupling as much as possible while still hearing the station. Now adjust the aerial tap to find a peak. When this is found it should be possible to further reduce the variometer coupling and re-tune for best signal. The detector circuit tap should be set as low as possible to provide the best selectivity of the set.

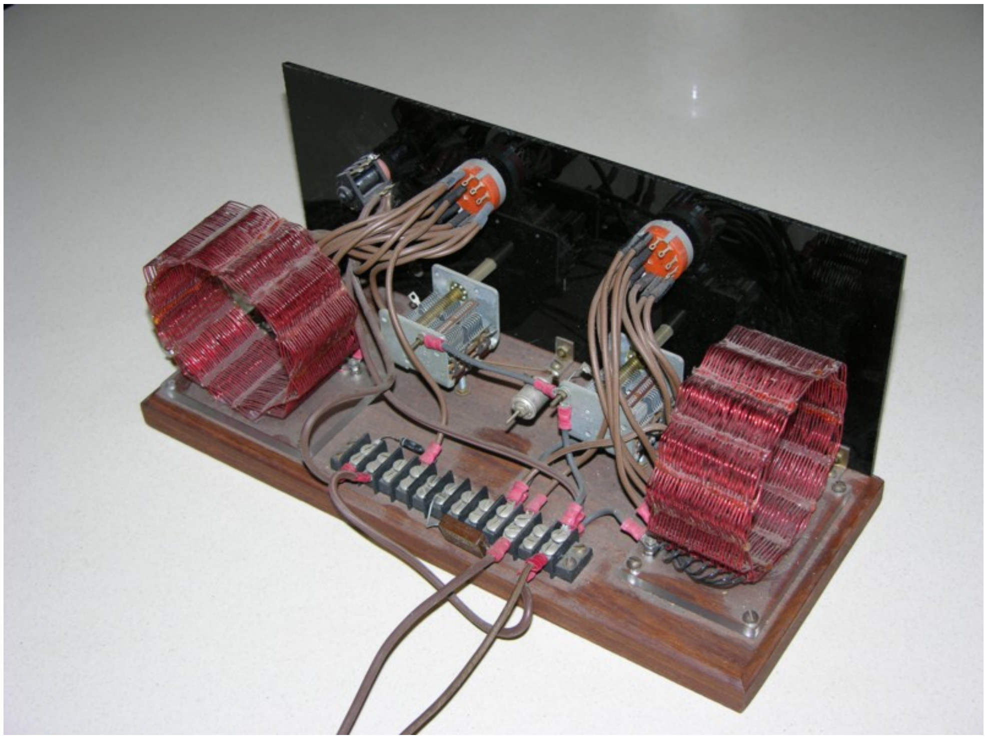


Detector set to tap no. 7

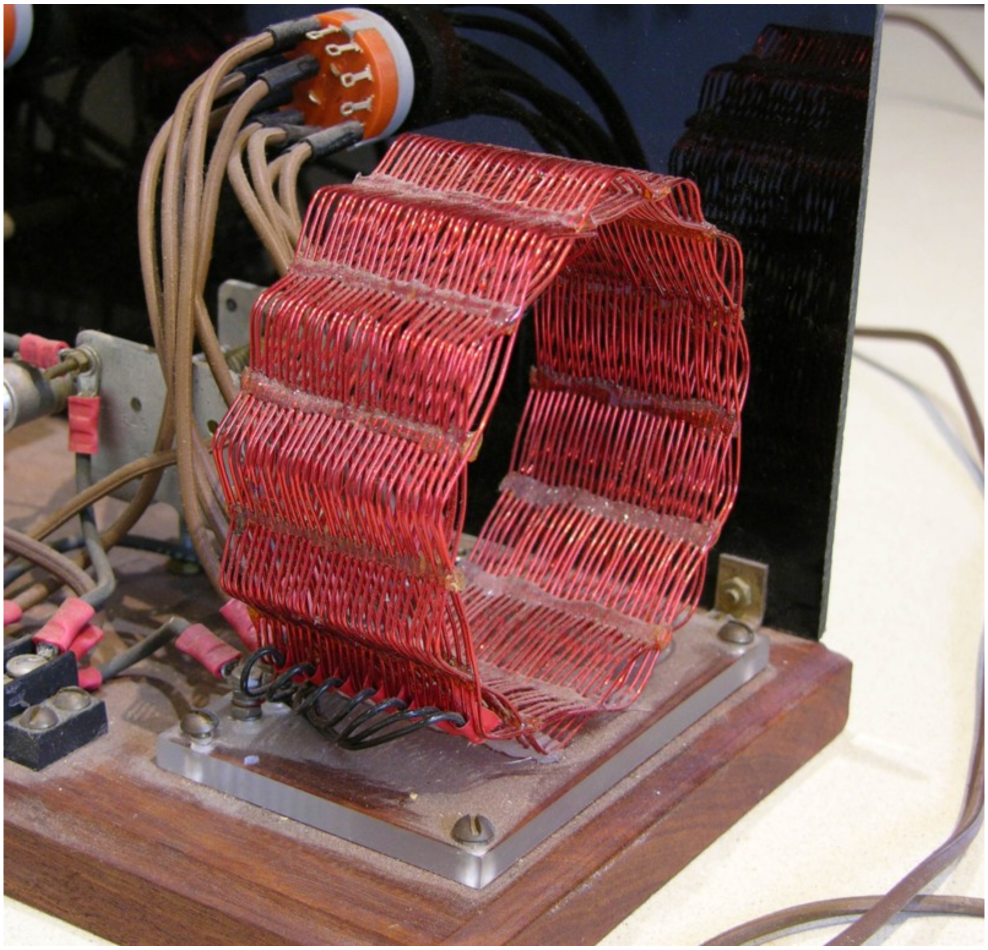
With careful operation of the controls it should be possible to select even quite weak stations from amongst the stronger signals. With a skilled operator, the performance of this crystal radio is quite remarkable.

A Variation on the Design

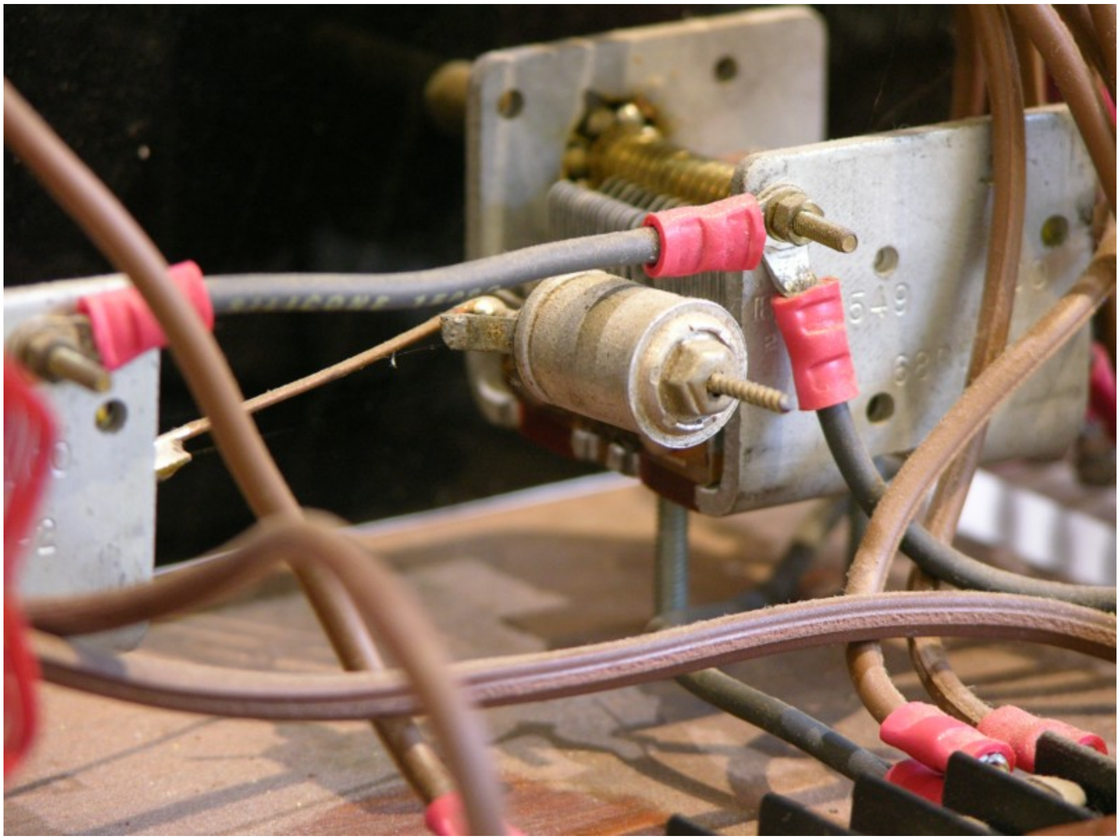
When cleaning out my shed the other day I came across a set that I had constructed many years ago. It is a variation on the Orpheus design with a small beehive trimmer capacitor used to control the coupling between the tuned circuits in place of the variometer. Also, a different approach to the coil winding design is used.



Rear View



Aerial Coil - Note the alternative method used to reduce inter-winding capacitance.



The small trimmer capacitor is used to couple the tuned circuits. Like the design using a variometer, it is adjusted to optimise the trade-off between sensitivity and selectivity.

How to make a batteryless (crystal set) radio

CRYSTAL SET

The simplest radio receiver, known as a Crystal Set, consists of nothing more than a coil, tuning capacitor, diode detector, and a pair of earphones. A typical circuit diagram for a Crystal Set Radio is given below where inductor or coil L1 is tuned by variable capacitor VC1 to the transmitter frequency. Diode D1 demodulates the signal, which is fed straight to the earphones. There is no amplification.

A long (at least 20 metres), high (17 metres or more) aerial and a good earth (a buried biscuit tin or a metre of copper pipe driven into damp ground) are required in order to ensure audible headphone reception. The earphones originally used with these receivers had an impedance of around 4000 ohms and were very sensitive (and heavy and uncomfortable). They are no longer available, but a crystal earpiece, which relies on the piezoelectric effect, will give acceptable results.

Low impedance ”Walkman” type earphones are NOT suitable.

Miscellaneous: L1- Ferrite Rod, 100mm(4 inch)x9mm/10mm dia., with coil.

Crystal earpiece and jack socket to suit; plastic control knob; plastic insulated flexible cable for aerial wire, downlead and earth connection, 30 meters minimum; buried biscuit tin or 1 meter of copper pipe for earth system; 50gm reel of 26SWG enamelled copper wire, for tuning coil; card and glue for coil former; multistrand connecting wire; crocodile clips or terminals for aerial and earth lead connection; solder, etc.

READ MY EXPERIENCES- HOW EASILY I MADE A BATTERYLESS RADIO

DRAWBACKS

Quite apart from the absence of amplification, two factors seriously limit the performance of crystal receivers. Germanium diodes become increasingly reluctant to conduct as the applied voltage falls below 0.2V, and this makes the receiver insensitive to weak signals. Silicon diodes have a threshold of around 0.6V, and are, therefore, unsuitable for circuits of this kind.

** Silicon diodes like 1N4001 are not suitable*

The earphone loading imposes heavy damping on the tuned circuit, hence, reduces its ability to separate signals. With such low selectivity insensitivity can be a blessing, and crystal sets are normally only capable of receiving a single, strong transmission on the long and medium wavebands. They will sometimes receive more than one if a shortwave coil is fitted.

The aerial and diode can be connected to tappings on the tuning coil in order to reduce damping, but the improvement in selectivity is usually at the expense of audio output. When valves cost a week’s wages and had to be powered by large dry batteries and lead/acid accumulators, the construction of simple receivers of this kind could be justified. With high performance transistors now costing only a few pence or cents, crystal sets are now regarded as ‘nostalgic pieces”. Some readers may, however, wish to build one out of curiosity, or for the novelty of having a receiver that **does not require a power supply.**

CIRCUIT DETAILS

Ferrite loop aerial L1 and polythene dielectric variable capacitor VC1 form the tuned circuit. Point contact germanium diode D1 (1N34 or OA47) demodulates the signal; capacitor C1 bypasses residual r.f. (radio frequency) to earth and also exhibits a reservoir action, enabling the a.f. (audio frequency) output to approach its peak value. The recovered audio signal is fed directly to a crystal earpiece. Signal voltages introduced in the ferrite loop aerial by the radiated magnetic field are much too much to produce an output from the detector, and the component is used here simply as a tuning coil. The ferrite core does, however, reduce the number of turns required for the coil winding, thereby reducing its resistance and increasing its audio quality.

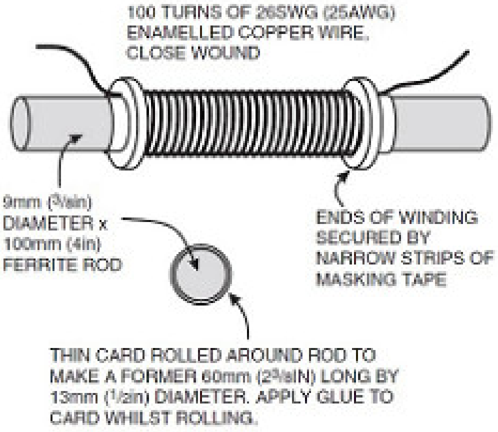
COIL DETAILS

Full construction and winding details for the ferrite tuning/ aerial coil L1 are shown in figure.

The coil is made from 26 SWG(25 AWG) enamelled copper wire, close wound on a cardboard former.



100 TURNS OF 26SWG (25AWG) ENAMELLED COPPER WIRE, CLOSE WOUND
9mm (3/8in) DIAMETER x 100mm (4in) FERRITE ROD
ENDS OF WINDING SECURED BY NARROW STRIPS OF MASKING TAPE
THIN CARD ROLLED AROUND ROD TO MAKE A FORMER 60mm (2 3/8IN) LONG BY 13mm (1/2in) DIAMETER. APPLY GLUE TO CARD WHILST ROLLING.

The r.f. bypass capacitor C1 can in practice, be omitted with no noticeable reduction in performance. However, if the set is to be connected to either the headphone amplifier or speaker amplifier decribed next month, the component together with diode, load resistor, RX, must be included.

AMPLIFICATION Audio frequency amplification, after the diode detector will permit the use of low impedance Walkman type earphones or even loud speaker operation. It will do nothing, however, to overcome the diode's insensitivity to weak signals. For this we must have radio frequency amplification of the signals picked up by the aerial before they reach the detector(The standard circuit for a transistor portable receiver has three stages of radio frequency amplification ahead of the diode).

For amplification, you can use a simple audio amplifier using LM386.

[57] **ABSTRACT**

The invention is directed to the method of utilizing the unpaired electron spins in ferro magnetic and other materials as a source of magnetic fields for producing power without any electron flow as occurs in normal conductors, and to permanent magnet motors for utilizing this method to produce a power source. In the practice of the invention the unpaired electron spins occurring within permanent magnets are utilized to produce a motive power source solely through the superconducting characteristics of a permanent magnet and the magnetic flux created by the magnets are controlled and concentrated to orient the magnetic forces generated in such a manner to do useful continuous work, such as the displacement of a rotor with respect to a stator. The timing and orientation of magnetic forces at the rotor and stator components produced by permanent magnets to produce a motor is accomplished with the proper geometrical relationship of these components.

PERMANENT MAGNET MOTOR

FIELD OF THE INVENTION

The invention pertains to the field of permanent magnet motor devices solely using the magnetic fields created thereby to product motive power.

BACKGROUND OF THE INVENTION

Conventional electric motors employ magnetic forces to produce either rotative or linear motion. Electric motors operate on the principle that when a conductor is located in a magnetic field which carries current a magnetic force is exerted upon it.

Normally, in a conventional electric motor, the rotor, or stator, or both, are so wired that magnetic fields created by electromagnetics may employ attraction, repulsion, or both types of magnetic forces, to impose a force upon the armature to cause rotation, or to cause the armature to be displaced in a linear path. Conventional electric motors may employ permanent magnets either in the armature or stator components, but in the art heretofore known the use of permanent magnets in either the stator or armature require the creation of an electromagnetic field to act upon the field produced by the permanent magnets, and switching means are employed to control the energization of the electromagnets and the orientation of the magnetic fields, to produce the motive power.

It is my belief that the full potential of magnetic forces existing in permanent magnets has not been recognized or utilized because of incomplete information and theory with respect to the atomic motion occurring within a permanent magnet. It is my belief that a presently unnamed atomic particle is associated with the electron movement of a superconducting electromagnet and the lossless current flow of Amperian currents in permanent magnets. The unpaired electron flow is similar in both situations. This small particle is believed to be opposite in charge and to be located at right angles to the moving electron, and the particle would be very small as to penetrate all known elements, in their various states as well as their known compounds, unless they have unpaired electrons which capture these particles as they endeavor to pass therethrough.

Ferro electrons differ from those of most elements in that they are unpaired, and being unpaired they spin around the nucleus in such a way that they respond to magnetic fields as well as creating one themselves. If they were paired, their magnetic fields would cancel out. However, being unpaired they create a measurable magnetic field if their spins have been oriented in one direction. The spins are at right angles to their magnetic fields.

In niobium superconductors at a critical state, the magnetic lines of force cease to be at right angles. This change must be due to establishing the required conditions for unpaired electronic spins instead of electron flow in the conductor, and the fact that very powerful electromagnets that can be formed with superconductors illustrates the tremendous advantage of producing the magnetic field by unpaired electron spins rather than conventional electron flow.

In a superconducting metal, wherein the electrical resistance becomes greater in the metal than the proton resistance, the flow turns to electron spins and the positive particles flow parallel in the metal in the manner occurring in a permanent magnet where a powerful flow of magnetic positive particles or magnetic flux causes the unpaired electrons to spin at right angles. Under cryogenic superconduction conditions the freezing of the crystals in place makes it possible for the spins to continue, and in a permanent magnet the grain orientation of the magnetized material results in the spins permitting them to continue and for the flux to flow parallel to the metal.

In a superconductor, at first the electron is flowing and the positive particle is spinning; later, when critical, the reverse occurs, i.e., the electron is spinning and the positive particle is flowing at right angles. These positive particles will thread or work their way through the electron spins present in the metal.

In a sense, a permanent magnet may be considered the only room temperature superconductor. It is a superconductor because the electron flow does not cease, and this electron flow can be made to do work because of the magnetic field it supplies. Previously, this source of power has not been used because it was not possible to modify the electron flow to accomplish the switching functions of the magnetic field. Such switching functions are common in a conventional electric motor where electrical current is employed to align the much greater electron current in the iron pole pieces and concentrate the magnetic field at the proper places to give the thrust necessary to move the motor armature. In a conventional electric motor, switching is accomplished by the use of brushes, commutators, alternating current, or other known means.

In order to accomplish the switching function in a permanent magnet motor, it is necessary to shield the magnetic leakage so that it will not appear as too great a loss factor at the wrong places. The best method to accomplish this is to use the superconductor of magnetic flux and concentrate it to the place where it will be the most effective. Timing and switching can be achieved in a permanent magnet motor by concentrating the flux and using the proper geometry of the motor rotor and stator to make most effective use of the magnetic fields generated by the electron spins. By the proper combination of materials, geometry and magnetic concentration, it is possible to achieve a mechanical advantage of high ratio, greater than 100 to 1, capable of producing a continuous motive force.

To my knowledge, previous work done with permanent magnets, and motive devices utilizing permanent magnets, have not achieved the result desired in the practice of the inventive concept, and it is with the proper combination of materials, geometry and magnetic concentration that the presence of the magnetic spins within a permanent magnet may be utilized as a motive force.

SUMMARY OF THE INVENTION

It is an object of the invention to utilize the magnetic spinning phenomenon of unpaired electrons occurring in ferro magnetic material to produce the movement of a mass in a unidirectional manner as to permit a motor to be driven solely by magnetic forces as occurring within permanent magnets. In the practice of the inventive concepts, motors of either linear or rotative types may be produced.

It is an object of the invention to provide the proper combination of materials, geometry and magnetic concentration to utilize the force generated by unpaired electron spins existing in permanent magnets to power a motor. Whether the motor constitutes a linear embodiment, or a rotary embodiment, in each instance the "stator" may consist of a plurality of permanent magnets fixed relative to each other in space relationship to define a track, linear in form in the linear embodiment, and circular in form in the rotary embodiment. An armature magnet is located in spaced relationship to such track defined by the stator magnets wherein an air gap exists therebetween. The length of the armature magnet is defined by poles of opposite polarity, and the length of the armature magnet is disposed relative to the track defined by the stator magnets in the direction of the path of movement of the armature magnet as displaced by the magnetic forces.

The stator magnets are so mounted that poles of like polarity are disposed toward the armature magnet and as the armature magnet has poles which are both attracted to and repelled by the adjacent pole of the stator magnets, both attraction and repulsion forces act upon the armature magnet to produce the relative displacement between the armature and stator magnets.

The continuing motive force producing displacement between the armature and stator magnets results from the relationship of the length of the armature magnet in the direction of its path of movement as related to the dimension of the stator magnets, and the spacing therebetween, in the direction of the path of armature magnet movement. This ratio of magnet and magnet spacings, and with an acceptable air gap spacing between the stator and armature magnets, will produce a resultant force upon the armature magnet which displaces the armature magnet across the stator magnet along its path of movement.

In the practice of the invention movement of the armature magnet relative to the stator magnets results from a combination of attraction and repulsion forces existing between the stator and armature magnets. By concentrating the magnetic fields of the stator and armature magnets the motive force imposed upon the armature magnet is intensified, and in the disclosed embodiments such magnetic field concentration means are disclosed.

The disclosed magnetic field concentrating means comprise a plate of high magnetic field permeability disposed adjacent one side of the stator magnets in substantial engagement therewith. This high permeability material is thus disposed adjacent poles of like polarity of the stator magnets. The magnetic field of the armature magnet may be concentrated and directionally oriented by bowing the armature magnet, and the magnetic field may further be concentrated by shaping the pole ends of the armature magnet to concentrate the magnet field at a relatively limited surface at the armature magnet pole ends.

Preferably, a plurality of armature magnets are used which are staggered with respect to each other in the direction of armature magnet movement. Such an offsetting or staggering of the armature magnets distributes the impulses of force imposed upon the armature magnets and results in a smoother application of forces to the armature magnet producing a smoother and more uniform movement of the armature component.

In the rotary embodiment of the permanent magnet motor of the invention the stator magnets are arranged in a circle, and the armature magnets rotate about the stator magnets. Means are disclosed for producing relative axial displacement between the stator and armature magnets to adjust the axial alignment thereof, and thereby regulate the magnitude of the magnetic forces being imposed upon the armature magnets. In this manner the speed of rotation of the rotary embodiment may be regulated.

BRIEF DESCRIPTION OF THE DRAWINGS

The aforementioned objects and advantages of the invention will be appreciated from the following description and accompanying drawings wherein:

FIG. **1** is a schematic view of electron flow in a superconductor indicating the unpaired electron spins,

FIG. **2** is a cross-sectional view of a superconductor under a critical state illustrating the electron spins,

FIG. **3** is a view of a permanent magnet illustrating the flux movement therethrough,

FIG. **4** is a cross-sectional view illustrating the diameter of the magnet of FIG. **3**,

FIG. **5** is an elevational representation of a linear motor embodiment of the permanent magnet motor of the invention illustrating one position of the armature magnet relative to the stator magnets, and indicating the magnetic forces imposed upon the armature magnet,

FIG. **6** is a view similar to FIG. **5** illustrating displacement of the armature magnet relative to the stator magnets, and the influence of magnetic forces thereon at this location,

FIG. **7** is a further elevational view similar to FIGS. **5** and **6** illustrating further displacement of the armature magnet to the left, and the influence of the magnetic forces thereon,

FIG. **8** is a top plan view of a linear embodiment of the inventive concept illustrating a pair of armature magnets in linked relationship disposed above the stator magnets,

FIG. **9** is a diametrical, elevational, sectional view of a rotary motor embodiment in accord with the invention as taken along section IX—IX of FIG. **10**, and

FIG. **10** is an elevational view of the rotary motor embodiment as taken along section X—X of FIG. **9**.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

In order to better understand the theory of the inventive concept, reference is made to FIGS. **1** through **4**. In FIG. **1** a superconductor **1** is illustrated having a positive particle flow as represented by arrow **2**, the unpaired electrons of the ferrous conducting material **1** spin at right angles to the proton flow in the conductor as represented by the spiral line and arrow **3**. In accord with the theory of the invention the spinning of the ferrous unpaired electrons results from the atomic structure of ferrous materials and this spinning atomic particle is believed to be opposite in charge and located at right angles to the moving electrons. It is assumed to be very small in size capable of penetrating other elements and their compounds unless they have unpaired electrons which capture these particles as they endeavor to pass therethrough.

The lack of electrical resistance of conductors at a critical superconductor state has long been recognized, and superconductors have been utilized to produce very high magnetic flux density electromagnets. FIG. **2** represents a cross section of a critical superconductor and the electron spins are indicated by the arrows **3**.

A permanent magnet may be considered a superconductor as the electron flow therein does not cease, and is without resistance, and unpaired electric spinning particles exist which, in the practice of the invention, are utilized to produce motor force. FIG. **3** illustrates a horseshoe shaped permanent magnet at 4 and the magnetic flux therethrough is indicated by arrows 5, the magnetic flow being from the south pole to the north pole and through the magnetic material. The accumulated electron spins occurring about the diameter of the magnet 5 are represented at 6 in FIG. 4, and the spinning electron particles spin at right angles in the iron as the flux travels through the magnet material.

By utilizing the electron spinning theory of ferrous material electrons, it is possible with the proper ferromagnetic materials, geometry and magnetic concentration to utilize the spinning electrons to produce a motive force in a continuous direction, thereby resulting in a motor capable of doing work.

It is appreciated that the embodiments of motors utilizing the concepts of the invention may take many forms, and in the illustrated forms the basic relationships of components are illustrated in order to disclose the inventive concepts and principles.

The relationships of the plurality of magnets defining the stator 10 are best appreciated from FIGS. 5 through 8. The stator magnets 12 are preferably of a rectangular configuration, FIG. 8, and so magnetized that the poles exist at the large surfaces of the magnets, as will be appreciated from the N (North) and S (South) designations. The stator magnets include side edges 14 and 16 and end edges 18. The stator magnets are mounted upon a supporting plate 20, which is preferably of a metal material having a high permeability to magnetic fields and magnetic flux such as that available under the trademark Netic CoNetic sold by the Perfection Mica Company of Chicago, Illinois. Thus, the plate 20 will be disposed toward the south pole of the stator magnets 12, and preferably in direct engagement therewith, although a bonding material may be interposed between the magnets and the plate in order to accurately locate and fix the magnets on the plate, and position the stator magnets with respect to each other.

Preferably, the spacing between the stator magnets 12 slightly differs between adjacent stator magnets as such a variation in spacing varies the forces being imposed upon the armature magnet at its ends, at any given time, and thus results in a smoother movement of the armature magnet relative to the stator magnets. Thus, the stator magnets so positioned relative to each other define a track 22 having a longitudinal direction left to right as viewed in FIGS. 5 through 8.

In FIGS. 5 through 7 only a single armature magnet 24 is disclosed, while in FIG. 8 a pair of armature magnets are shown. For purposes of understanding the concepts of the invention the description herein will be limited to the use of single armature magnet as shown in FIGS. 5 through 7.

The armature magnet is of an elongated configuration wherein the length extends from left to right, FIG. 5, and may be of a rectangular transverse cross-sectional shape. For magnetic field concentrating and orientation purposes the magnet 24 is formed in an arcuate bowed configuration as defined by concave surfaces 26 and convex surfaces 28, and the poles are defined at the ends of the magnet as will be appreciated from FIG. 5. For further magnetic field concentrating purposes the ends of the armature magnet are shaped by beveled surfaces 30 to minimize the cross-sectional area at the magnet ends at 32, and the magnetic flux existing between the poles of the armature magnet are as indicated by the light dotted lines. In like manner the magnetic fields of the stator magnets 12 are indicated by the light dotted lines.

The armature magnet 24 is maintained in a spaced relationship above the stator track 22. This spacing may be accomplished by mounting the armature magnet upon a slide, guide or track located above the stator magnets, or the armature magnet could be mounted upon a wheeled vehicle carriage or slide supported upon a nonmagnetic surface or guideway disposed between the stator magnets and the armature magnet. To clarify the illustration, the means for supporting the armature magnet 24 is not illustrated and such means form no part of invention, and it is to be understood that the means supporting the armature magnet prevents the armature magnet from moving away from the stator magnets, or moving closer thereto, but permits free movement of the armature magnet to the left or right in a direction parallel to the track 22 defined by the stator magnets.

It will be noted that the length of the armature magnet 24 is slightly greater than the width of two of the stator magnets 12 and the spacing therebetween. The magnetic forces acting upon the armature magnet when in the position of FIG. 5 will be repulsion forces 34 due to the proximity of like polarity forces and attraction forces at 36 because of the opposite polarity of the south pole of the armature magnet, and the north pole field of the sector magnets. The relative strength of this force is represented by the thickness of the force line.

The resultant of the force vectors imposed upon the armature magnet as shown in FIG. 5 produce a primary force vector 38 toward the left, FIG. 5, displacing the armature magnet 24 toward the left. In FIG. 6 the magnetic forces acting upon the armature magnet are represented by the same reference numerals as in FIG. 5. While the forces 34 constitute repulsion forces tending to move the north pole of the armature magnet away from the stator magnets, the attraction forces imposed upon the south pole of the armature magnet and some of the repulsion forces, tend to move the armature magnet further to the left, and as the resultant force 38 continues to be toward the left the armature magnet continues to be forced to the left.

FIG. 7 represents further displacement of the armature magnet 24 to the left with respect to the position of FIG. 6, and the magnetic forces acting thereon are represented by the same reference numerals as in FIGS. 5 and 6, and the stator magnet will continue to move to the left, and such movement continues the length of the track 22 defined by the stator magnets 12.

Upon the armature magnet being reversed such that the north pole is positioned at the right as viewed in FIG. 5, and the south pole is positioned at the left, the direction of movement of the armature magnet relative to the stator magnets is toward the right, and the theory of movement is identical to that described above.

In FIG. 8 a plurality of armature magnets 40 and 42 are illustrated which are connected by links 44. The armature magnets are of a shape and configuration identical to that of the embodiment of FIG. 5, but the magnets are staggered with respect to each other in the direction of magnet movement, i.e., the direction of the track 22 defined by the stator magnets 12. By so staggering a plurality of armature magnets a smoother movement of the interconnected armature magnets is produced as compared when using a single armature magnet as there is variation in the forces acting upon each armature magnet as it moves above the track 22 due to the change in magnetic forces imposed thereon. The use of several armature magnets tends to "smooth out" the application of forces imposed upon linked armature magnets, resulting in a smoother movement of the armature magnet assembly. Of course, any number of armature magnets may be interconnected, limited only by the width of the stator magnet track 22.

In FIGS. 9 and 10 a rotary embodiment embracing the inventive concepts is illustrated. In this embodiment the principle of operation is identical to that described above, but the orientation of the stator and armature magnets is such that rotation of the armature magnets is produced about an axis, rather than a linear movement being achieved.

In FIGS. 9 and 10 a base is represented at **46** serving as a support for a stator member **48**. The stator member **48** is made of a nonmagnetic material, such as synthetic plastic, aluminum, or the like. The stator includes a cylindrical surface **50** having an axis, and a threaded bore **52** is concentrically defined in the stator. The stator includes an annular groove **54** receiving an annular sleeve **56** of high magnetic field permeability material such as Netic Co-Netic and a plurality of stator magnets **58** are affixed upon the sleeve **56** in spaced circumferential relationship as will be apparent in FIG. **10**. Preferably, the stator magnets **58** are formed with converging radial sides as to be of a wedge configuration having a curved inner surface engaging sleeve **56**, and a convex outer pole surface **60**.

The armature **62**, in the illustrated embodiment, is of a dished configuration having a radial web portion, and an axially extending portion **64**. The armature **62** is formed of a nonmagnetic material, and an annular belt receiving groove **66** is defined therein for receiving a belt for transmitting power from the armature to a generator, or other power consuming device. Three armature magnets **68** are mounted on the armature portion **64**, and such magnets are of a configuration similar to the armature magnet configuration of FIGS. **5** through **7**. The magnets **68** are staggered with respect to each other in a circumferential direction wherein the magnets are not disposed as 120° circumferential relationships to each other. Rather, a slight angular staggering of the armature magnets is desirable to "smooth out" the magnetic forces being imposed upon the armature as a result of the magnetic forces being simultaneously imposed upon each of the armature magnets. The staggering of the armature magnets **68** in a circumferential direction produces the same effect as the staggering of the armature magnets **40** and **42** as shown in FIG. **8**.

The armature **62** is mounted upon a threaded shaft **70** by antifriction bearings **72**, and the shaft **70** is threaded into the stator threaded bore **52**, and may be rotated by the knob **74**. In this manner rotation of the knob **74**, and shaft **70**, axially displaces the armature **62** with respect to the stator magnets **58**, and such axial displacement will very the magnitude of the magnetic forces imposed upon the armature magnets **68** by the stator magnets thereby controlling the speed of rotation of the armature.

As will be noted from FIGS. 4–7 and 9 and 10, an air gap exists between the armature magnet or magnets and the stator magnets and the dimension of this spacing, effects the magnitude of the forces imposed upon the armature magnet or magnets. If the distance between the armature magents, and the stator magnets is reduced the forces imposed upon the armature magnets by the stator magnets are increased, and the resultant force vector tending to displace the armature magnets in their path of movement increases. However, the decreasing of the spacing between the armature and stator magnets creates a "pulsation" in the movement of the armature magnets which is objectionable, but can be, to some extent, minimized by using a plurality of armature magnets. The increasing of the distance between the armature and stator magnets reduces the pulsation tendency of the armature magnet, but also reduces the magnitude of the magnetic forces imposed upon the armature magnets. Thus, the most effective spacing between the armature magnets. Thus, the most effective spacing between the armature and stator magnets is that spacing which produces the maximum force vector in the direction of armature magnet movement, with a minimum creation of objectionable pulsation.

In the disclosed embodiments the high permeability plate **20** and sleeve **56** are disclosed for concentrating the magnetic field of the stator magnets, and the armature magnets are bowed and have shaped ends for magnetic field concentration purposes. While such magnetic field concentration means result in higher forces imposed upon the armature magnets for given magnet intensities, it is not intended that the inventive concepts be limited to the use of such magnetic field concentrating means.

As will be appreciated from the above description of the invention, the movement of the armature magnet or magnets resultsfrom the described relationship of components. The length of the armature magnets as related to the width of the stator magnets and spacing therebetween, the dimension of the air gap and the configuration of the magnetic field, combined, produce the desired result and motion. The inventive concepts may be practiced even though these relationships may be varied within limits not yet defined and the invention is intended to encompass all dimensional relationships which achieve the desired goal of armature movement. By way of example, with respect to FIGS. 4–7, the following dimensions were used in an operating prototype:

The length of armature magnet **24** is 3⅛", the stator magnets **12** are 1" wide, ¼" thick and 4" long and grain oriented. The air gap between the poles of the armature magnet and the stator magnets is approximately 1½" and the spacing between the stator magnets is approximately ½" inch.

In effect, the stator magnets define a magnetic field track of a single polarity transversely interrupted at spaced locations by the magnetic fields produced by the lines of force existing between the poles of the stator magnets and the unidirectional force exerted on the armature magnet is a result of the repulsion and attraction forces existing as the armature magnet traverses this magnetic field track.

It is to be understood that the inventive concept embraces an arrangement wherein the armature magnet component is stationary and the stator assembly is supported for movement and constitutes the moving component, and other variations of the inventive concept will be apparent to those skilled in the art without departing from the scope thereof. As used herein the term "track" is intended to include both linear and circular arrangements of the static magnets, and the "direction" or "length" of the track is that direction parallel or concentric to the intended direction of armature magnet movement.

I claim:

1. A permanent magnet motor comprising, in combination, a stator track defining a track direction and having first and second sides and composed of a plurality of track permanent magnets each having first and second poles of opposite polarity, said magnets being disposed in side-by-side relationship having a spacing between adjacent magnets and like poles defining said track sides, an elongated armature permanent magnet located on one of said track sides for relative movement thereto and in spaced relationship to said track side wherein an air gap exists between said armature magnet and said track magnets, said armature magnet having first and second poles of opposite polarity located at the opposite ends of said armature magnet defining the length thereof, the length of said armature magnet being disposed in a direction in general alignment with the direction of said track, the spacing of said armature magnet poles from said track associated side and the length of said armature magnet as related to the width and spacing of said track magnets in the direction of said track being such as to impose a continuous force on said armature magnet in said general direction of said track.

2. In a permanent magnet motor as in claim 1 wherein the spacing between said poles of said armature magnet and the adjacent stator track side are substantially equal.

3. In a permanent magnet motor as in claim 1 wherein the spacing between adjacent track magnets varies.

4. In a permanent magnet motor as in claim 1 wherein a plurality of armature magnets are disposed on a common side of said stator track, said armature magnets being mechanically interconnected.

5. In a permanent magnet motor as in claim 4 wherein said armature magnets are staggered with respect to each other in the direction of said track.

6. In a permanent magnet motor as in claim 1 wherein magnetic field concentrating means are associated with said track magnets.

7. In a permanent magnet motor as in claim 6 wherein said field concentrating means comprises a sheet of magnetic material of high magnetic field permeability engaging side and pole of said track magnets opposite to that side and pole disposed toward said armature magnet.

8. In a permanent magnet motor as in claim 1 wherein said armature magnet is of an arcuate configuration in its longitudinal direction bowed toward said track, said said armature magnet having ends shaped to concentrate the magnetic field at said ends.

9. In a permanent magnet motor as in claim 1 wherein said stator track is of a generally linear configuration, and means supporting said armature magnet relative to said track for generally linear movement of said armature magnet.

10. In a permanent magnet motor as in claim 1 wherein said stator track magnets define a circle having an axis, an armature rotatably mounted with respect to said track and concentric and coaxial thereto, said armature magnet being mounted upon said armature.

11. In a permanent magnet motor as in claim 10, means axially adjusting said armature relative to said track whereby the axial relationship of said armature magnet and said stator magnets may be varied to adjust the rate of rotation of said armature.

12. In a permanent magnet motor as in claim 10 wherein a plurality of armature magnets are mounted on said armature.

13. In a permanent magnet motor as in claim 12 wherein said armature magnets are circumferentially nonuniformily spaced on said armature.

14. A permanent magnet motor comprising, in combination, a stator comprising a plurality of circumferentially spaced stator permanent magnets having poles of opposite polarity, said magnets being arranged to substantially define a circle having an axis, the poles of said magnets facing in a radial direction with respect to said axis and poles of the same polarity facing away from said axis and the poles of opposite polarity facing toward said axis, an armature mounted for rotation about said axis and diposed adjacent said stator, at least one armature permanent magnet having poles of opposite polarity mounted on said armature and in radial spaced relationship to said circle of stator magnets, said armature magnet poles extending in the circumferential direction of armature rotation, the spacing of said armature magnet poles from said stator magnets and the circumferential length of said armature magnet and the spacing of said stator magnets being such as to impose a continuing circumferential force on said armature magnet to rotate said armature.

15. In a permanent magnet motor as in claim 14 wherein a plurality of armature magnets are mounted upon said armature.

16. In a permanent magnet motor as in claim 14 wherein said armature magnets are asymmetrically circumferentially spaced on said armature.

17. In a permanent magnet motor as in claim 14 wherein the poles of said armature magnet are shaped to concentrate the magnetic field thereof.

18. In a permanent magnet motor as in claim 14, magnetic field concentrating means associated with said stator magnets concentrating the magnetic fields thereof at the spacings between adjacent stator magnets.

19. In a permanent magnet motor as in claim 18 wherein said magnet field concentrating means comprises an annular ring of high magnetic field permeability material concentric with said axis and in substantial engagement with poles of like polarity of said stator magnets.

20. In a permanent magnet motor as in claim 14 wherein said armature magnet is of an arcuate bowed configuration in the direction of said poles thereof defining a concave side and a convex side, said concave side being disposed toward said axis, and said poles of said armature magnet being shaped to concentrate the magnetic field between said poles thereof.

21. In a permanent magnet motor as in claim 14, means for axially displacing said stator and armature relative to each other to adjust the axial alignment of said stator and armature magnets.

22. The method of producing a unidirectional motive force by permanent magnets using a plurality of spaced stator permanent magnets having opposite polarity poles defining a track having a predetermined direction, and an armature magnet having a length defined by poles of opposite polarity movably mounted for movement relative to the track in the direction thereof, and of a predetermined length determined by the width and dimensions of said stator magnets comprising forming a magnetic field track by said stator magnets having a magnetic field of common polarity interrupted at spaced locations in a direction transverse to the direction of said magnetic field track by magnetic fields created by magnetic lines of force existing between the

poles of the stator magnets and positioning the armature magnet in spaced relation to said magnetic field track longitudinally related to the direction of the magnetic field track such a distance that the repulsion and attraction forces imposed on the armature magnet by said magnetic field track imposes a continuing unidirectional force on the armature magnet in the direction of the magnetic field track.

23. The method of producing a unidirectional motive force as in claim **22** including concentrating the magnetic fields created by magnetic lines of force between the poles of the stator magnets.

24. The method of producing a unidirectional motive force as in claim **22** including concentrating the magnetic field existing between the poles of the armature magnet.

25. The method of producing a unidirectional motive force as in claim **22** including concentrating the magnetic fields created by magnetic lines of force between the poles of the stator magnets and concentrating the magnetic field existing between the poles of the armature magnet.

26. The method of producing a motive force by permanent magnets wherein the unpaired electron spinning particles existing within a permanent magnet are utilized for producing a motive force comprising forming a stator magnetic field track by means of at least one permanent magnet, producing an armature magnetic field by means of a permament magnet and shaping and locating said magnetic fields in such a manner as to produce relative continuous unidirectional motion between said stator and armature field producing magnets.

27. The method of producing a motive force by permanent magnets as in claim **26** wherein said stator magnetic field is substantially of a single polarity.

28. The method of producing a motive force by permanent magnets as in claim **26** including concentrating the magnetic field of said stator field track and armature magnetic field.

[57] ABSTRACT

The invention is directed to the method of utilizing the unpaired electron spins in ferro magnetic and other materials as a source of magnetic fields for producing power without any electron flow as occurs in normal conductors, and to permanent magnet motors for utilizing this method to produce a power source. In the practice of the invention the unpaired electron spins occurring within permanent magnets are utilized to produce a motive power source solely through the superconducting characteristics of a permanent magnet and the magnetic flux created by the magnets are controlled and concentrated to orient the magnetic forces generated in such a manner to do useful continuous work, such as the displacement of a rotor with respect to a stator. The timing and orientation of magnetic forces at the rotor and stator components produced by permanent magnets to produce a motor is accomplished with the proper geometrical relationship of these components.

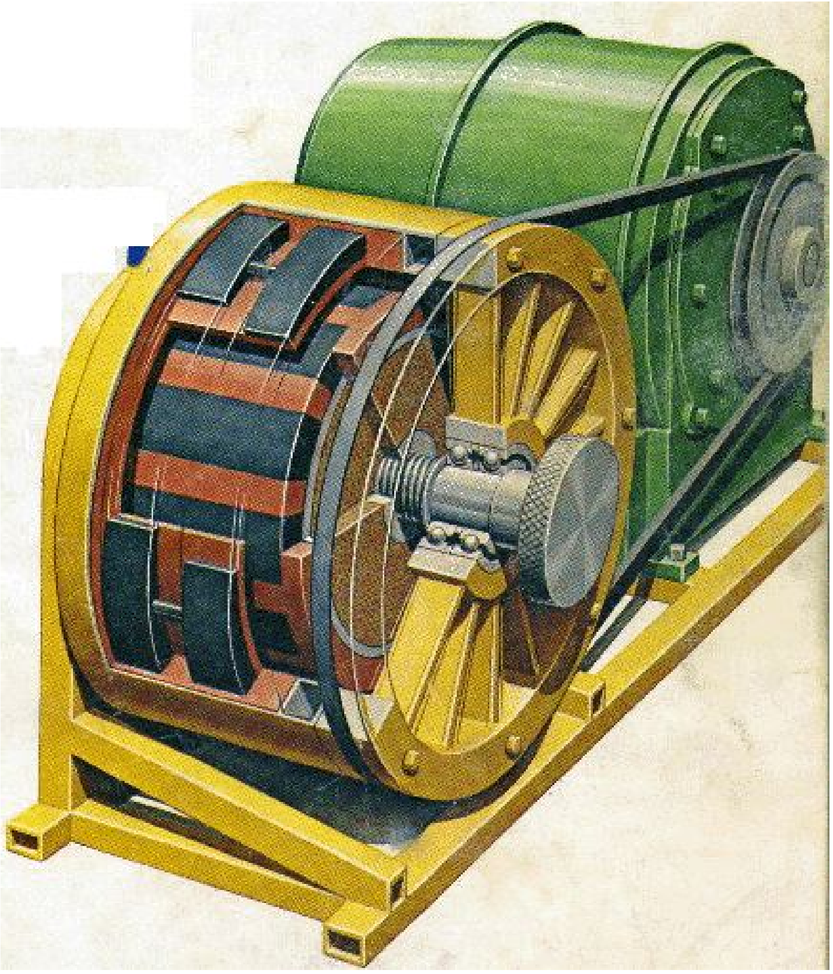

Figure 1

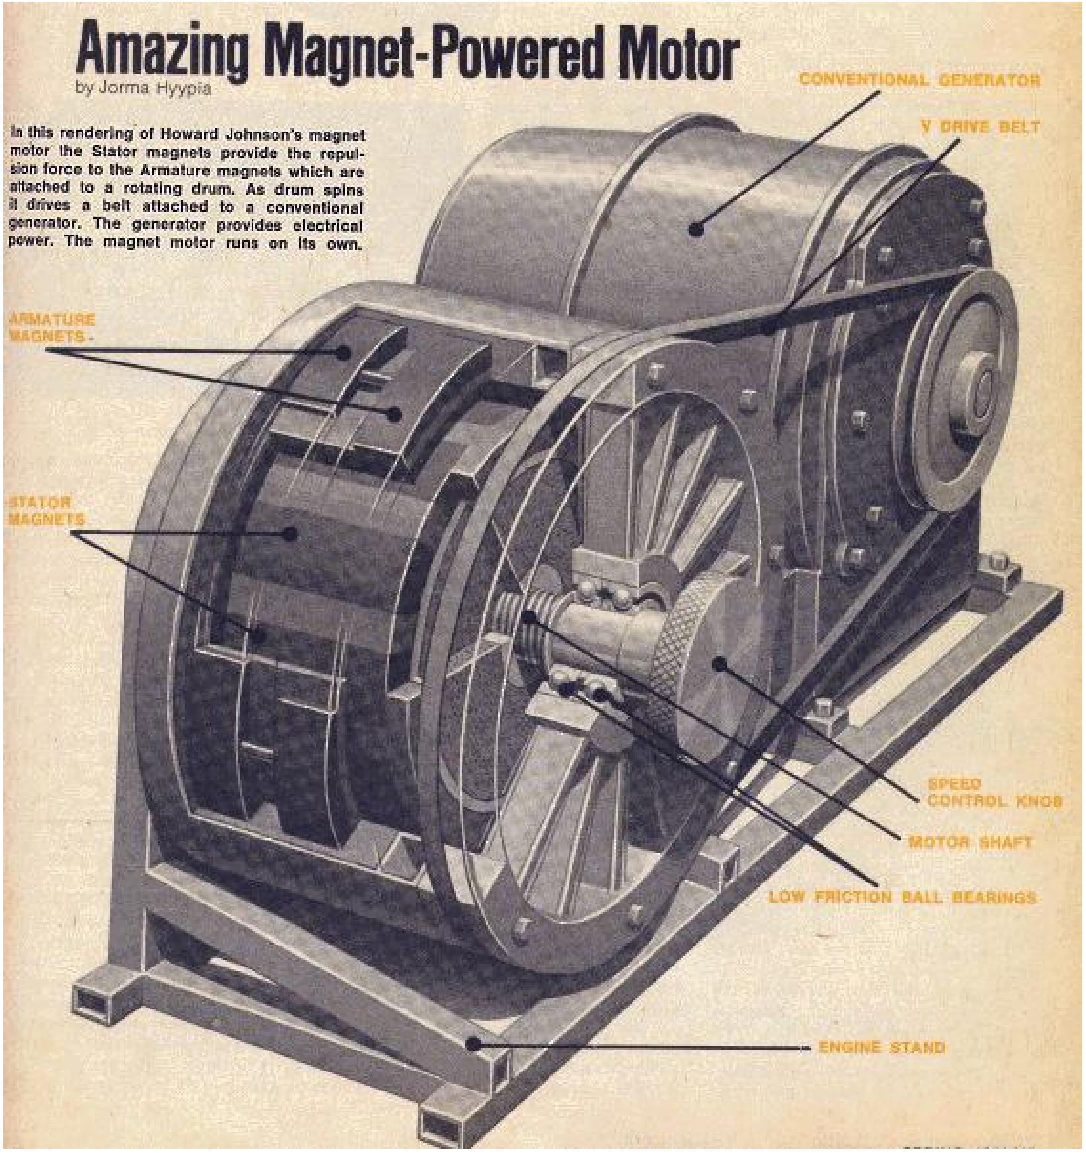


Amazing Magnet-Powered Motor

by Jorma Hyypia

In this rendering of Howard Johnson's magnet motor the Stator magnets provide the repulsion force to the Armature magnets which are attached to a rotating drum. As drum spins it drives a belt attached to a conventional generator. The generator provides electrical power. The magnet motor runs on its own.

Science & Mechanics (Spring 1980)

"Amazing Magnet-Powered Motor"

by
Jorma Hyypia

"We don't grant patents on perpetual motion machines," said the examiners at the U.S. Patent Office. "It won't work because it violates the law of Conservation of Energy," said one physicist after another. But because, inventor Howard Johnson is not the sort of man to be intimidated by such seemingly authoritative pronouncements, he now owns U.S. Patent No. 4,151,431 which describes how it is possible to generate motive power, as in a motor, using only the energy contained in the atoms of permanent magnets. That's right. Johnson has discovered how to build motors that run without an input of electricity or any other kind of external energy!

The monumental nature of the invention is obvious, especially in a world facing an alarming, escalating energy shortage. Yet inventor Johnson is not rushing to peddle his creation as the end-all solution to world- wide energy problems. He has more important work to do. First, there's the need to refine his laboratory prototypes into workable practical devices -in particular a 5,000-watt electric power generator already in the building. His second and perhaps more difficult major challenge: persuade a host of skeptics that his ideas are indeed practical.

Johnson, who has been coping with disbelievers for decades, can be very persuasive in a face-to-face encounter because he can not do more than merely theorize; he can demonstrate working models that unquestionably create motion using only permanent magnets. When this writer was urged by the editor of Science & Mechanics to make a thousand mile pilgrimage to Blacksburg, Virginia, to meet with the inventor, he went there as an "open-minded skeptic" and as a former research Scientist determined not to be fooled. Within two days, this former skeptic had become a believer. Here's why.

Doing the Unthinkable

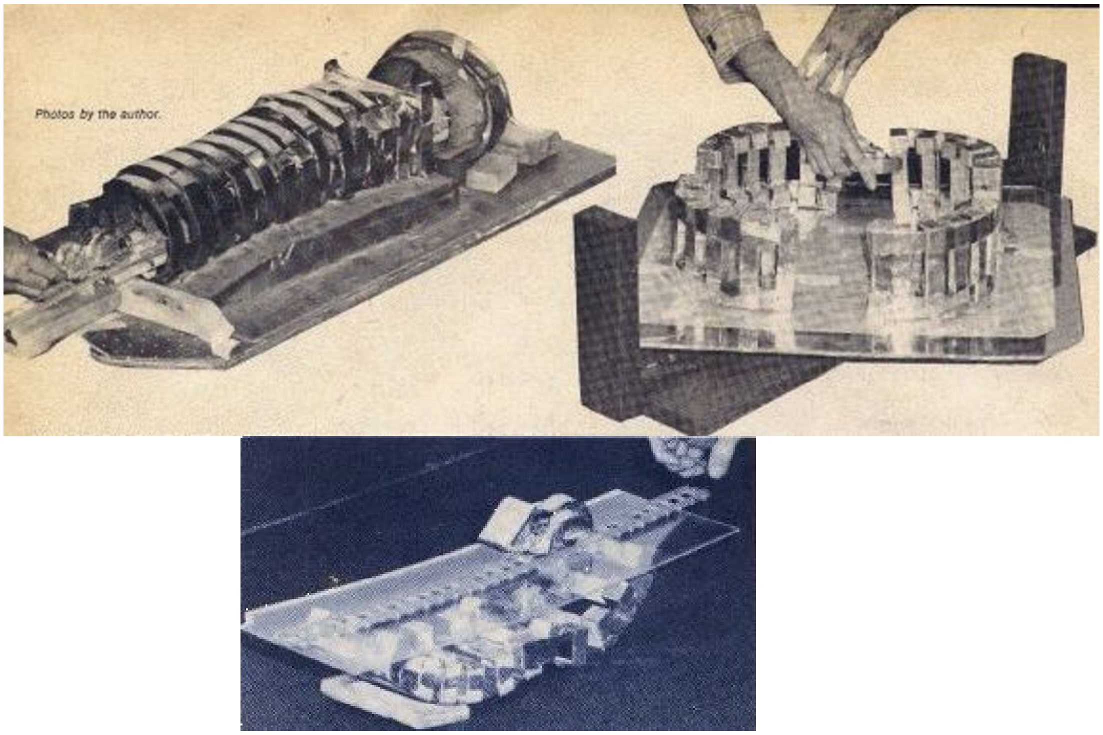
Howard Johnson refuses to view the "laws" of science as somehow sacred, so doing the unthinkable and succeeding is second nature to him. If a particular law gets in the way, he sees no harm in going around it for a while to see if there's something on the other side. Johnson explains the persistent opposition he experiences from the established scientific community this way: "Physics is a measurement science and physicists are especially determined to protect the &lsquo;Law&rsquo; of Conservation of Energy. Thus the physicists become game wardens who tell us what laws' we can't violate. In this case they don't even know what the game is. But they are so scared that I and my associates are going to violate some of these laws, that they have to get to the pass to head us off!"

The critics say Johnson offers a "free lunch" solution to energy problems, and that there can be no such thing. Johnson demurs, reminding repeatedly that he has never suggested that his invention provides something for nothing. He also points gut that no one talks about a "free lunch" when discussing extraction of enormous amounts of atomic power by means of nuclear reactors and atom bombs. In his mind, it's much the same thing.

Johnson is the first to admit he doesn't actually know where the power be has tapped derives. But he postulates that the energy may be associated with spinning electrons, perhaps in the form of a "presently unnamed atomic particle." How do other physicists react to Johnson's suggestion that there may be an atomic particle so far overlooked by nuclear physicists? Says Johnson: "I guess it&rsquo;s fair to say that most of them are revolted." On the other hand, a few converted scientists, including some who are associated with large and prestigious research laboratories, are intrigued enough to suggest that there should be a hunt for the answer, be it a "particle" or some other as yet unsuspected characteristic of atomic structure.

This article is prefaced with the foregoing brief summary of the ongoing controversy so that, in fairness to the inventor, we might all view his claims with open minds, even if it means temporary setting aside of cherished scientific concepts until more complete explanations are forthcoming. The main question to be answered here and now is this: Does Johnson permanent magnet motor work?

Before providing the answer, we need to face up to another question that undoubtedly nags in the minds of many readers: Is Johnson a bona fide researcher, or merely a "garage mechanic" mad inventor? As the following brief summary suggests, the inventor's credentials appear to be impeccable. Following seven years of college and university training, Johnson worked on atomic energy projects at Oak Ridge, did magnetics research for Burroughs company, and served as scientific consultant to Lukens Steel. He has participated in the development of medical electrical products, including injection devices. For the military he invented a ceramic muffler that makes a portable motor generator silent at 50 feet; this has been in production for the past 18 years. His contributions to the motor industry include: a hysteresis brake; non-locking brake materials for anti- skid application, new methods of curing brake linings; and a method of dissolving asbestos fibers. He has also worked on silencers for small motors, a super charger, and has perfected a 92-pole no-brush generator to go in the wheel of Lincoln automobiles as a skid control; that last item reduced the cost to one-eighth of the cost of an earlier design by utilizing metal-filled plastics for the armature and field. In all, Johnson is connected with more than 30 patents in the fields of chemistry and physics.



Photos by the author.

Figures 2, 3 & 4: Magnet Motor Models ~ Pictured here are three of the inventor's early models. Top left is a linear motor which propels a magnetic vehicle at high speeds through a series of rings. Top right is rotary motor upon which the prototype will be built. The 8-ounce manget, hand held to the large ring weighing 40 pounds, provides enough force to spin the entire assembly. In the third assembly above, the vehicle is propelled, in either direction, by the force of the large magnets arranged below tracks.

Sticky Tape Scientist

Despite his impressive credentials, this amiable and unpretentious inventor likes to characterize himself as a "Sticky tape" scientist. He sees no virtue in wasting time building fancy, elaborate equipment when more simple assemblies serve as well to test new ideas. The prototype devices shown in the photographs in this article were assembled with sticky tape and aluminum foil, the later material being used mainly to keep individual, permanent magnets packaged together so that they do not fly apart.

Perhaps the best way to describe what these three gadgets do is by reciting this writer's personal experiences during the interview demonstration. That way I will not merely be telling what the inventor says they do, but I will reveal what happened when I tried the experiments myself. When we start talking about how and why the things work as they do, well have to rely on the inventor&rsquo;s explanations.

The first item consists of more than a dozen foil-wrapped magnets assembled to form a broad arc. Each magnet is extended upward slightly at each end to form a low U-shape, the better to concentrate magnetic fields where they are needed. The overall curvature of the mass of magnets apparently has no particular significance except to show that the distance between these stator magnets and the moving vehicle is not critical. A transparent plastic sheet atop this magnet assembly supports a length of plastic model railroad track. The vehicle, basically a model railroad flatcar, supports a foil-wrapped pair of curved magnets, plus some sort of weight, in some cases merely a rock. The weight is needed to keep the vehicle down on the track, against the powerful magnetic forces that would otherwise push it askew. That 'is all there is to the construction of this representation of a "linear motor."

I was prepared to develop eye strain in an effort to detect some sort of motion in the vehicle. I need not have been concerned. The moment the inventor let go of the vehicle be carefully placed at one end of the track, it accelerated and literally zipped from one end to the other and flew onto the floor! Wow!

I tried the experiment myself, and could feel the powerful magnetic forces at work as I placed the vehicle on the track. I gently eased the vehicle to the critical starting point, taking great care not to exert any kind of forward push, even inadvertently. I let go, Zip! It was on the floor again, at the other end of the track. Knowing that I would be asked if the track might have had a slant, I reversed the vehicle and started it from the opposite end of the track. It worked just as effectively in the reverse direction. In fact, the vehicle can even navigate a respectable upgrade. In light of these tests, and considering the remarkable speed of the vehicle, you can discount any notion that this was a simple "coasting" effect.

Incidentally, the photograph shows the vehicle about half ways along the track. It was "frozen" there by the electronic flash used to make the picture; there is no way of "posing" the vehicle in that position short of tying it down.

The second device has the U-shaped magnets standing on end in a rough circular arrangement oddly reminiscent of England's Stonehenge. This assembly is mounted on a transparent plastic sheet supported on a plywood panel pivoted, underneath, on a free turning wheel obtained from a skateboard. As instructed, I eased the 8-ounce focusing magnet into the ring of larger magnets, keeping it at least four inches away from the ring. The 40 pound magnet assembly immediately began to turn and accelerated to a very respectable rotating speed which it maintained for as long as the focusing magnet was held in the magnetic field. When the focusing magnet was reversed, the large assembly turned in the opposite direction.

Since this assembly is clearly a crude sort of motor, there's no doubt that it is indeed possible to construct a motor powered solely by permanent magnets.

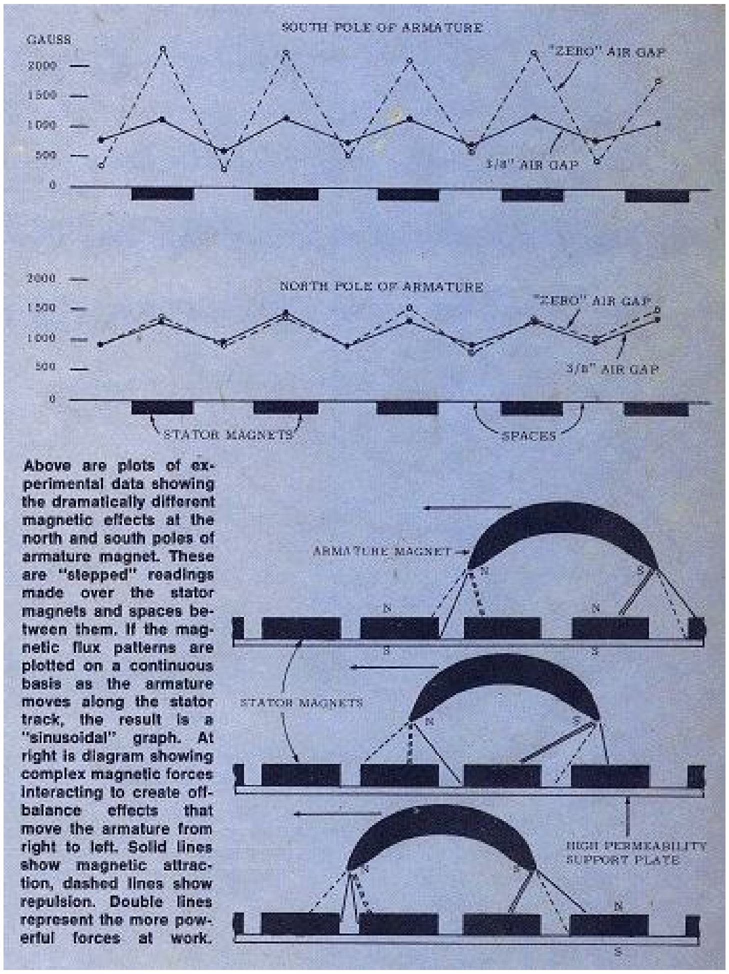
The third assembly, which looks like the bones of some prehistoric sea creature, consists of a tunnel constructed of rubber magnet material that can be easily bent to form rings. This was one of the demonstration models Johnson took to the U.S. Patent Office during his appeal proceedings. Normally the patent examiners spend only a few minutes with each patent applicant, but played with Johnson&rsquo;s devices for the better part of an hour. As the inventor was leaving, he overheard one sideline observer remark: "How would you like to follow that act?!"

It took Johnson about six years of legal hassling to finally obtain his patent, and he has been congratulated for his ultimate victory over patent office bureaucracy as well as for his inventiveness. One sign that he left the patent office more than a little shaken by the experience was the inclusion of diagrammatic material in the printed patent that does not belong there. So if you look up the patent, pay no attention to the "ferrite" graph on the first page; it belongs in some other patent!

The tunnel device of course worked very well in the inventor's office during my visit although Johnson observed that the rubber magnets are perhaps a thousand times weaker than the cobalt samarium magnets used the other assemblies. There's just one big problem with the more powerful magnets: they cost too much. According to the inventor, the magnets used to construct the Stonehenge rotating model are collectively worth more than one thousand dollars. But there's no need to depend solely on mass-production economies to bring the cost down to competitive levels. Johnson and U.S. Magnets and Alloy Co. are in the process of developing alternative, relatively low cost magnetic materials that perform very well.

How do they work?

The drawing that shows a curved "arcuate" armature magnet in three successive positions over a line of fixed stator magnets provides at least highly simplified insights into the theory of permanent magnet motive power generation. Johnson says curved magnets with sharp leading and trailing edges are important because they focus and concentrate the magnetic energy much more effectively than do blunt-end magnets. These arcuate magnets are made slightly longer than the lengths of two stator magnets plus the intervening space, in Johnson's setups about 3-1/8 inches long.



Above are plots of experimental data showing the dramatically different magnetic effects at the north and south poles of armature magnet. These are "stepped" readings made over the stator magnets and spaces between them. If the magnetic flux patterns are plotted on a continuous basis as the armature moves along the stator track, the result is a "sinusoidal" graph. At right is diagram showing complex magnetic forces interacting to create off-balance effects that move the armature from right to left. Solid lines show magnetic attraction, dashed lines show repulsion. Double lines represent the more powerful forces at work.

Note that the stator magnets all have their North faces upward, and that they are resting on a high magnetic permeability support plate that helps concentrate the force fields. The best gap between the end poles of the armature magnet and the stator magnets appears to be about 3/8 inch.

As the armature north pole passes over a magnet, it is repelled by the stator north pole; and there's an attraction when the north pole is passing over a space between the stator magnets. The exact opposite is of course true with respect to the armature South pole. It is attracted when passing over a stator magnet, repelled when passing over a space.

The various magnetic forces that come into play are extremely complex, but the drawing shows some of the fundamental relationships. Solid lines represent attraction forces, dashed lines represent repulsion forces, and double lines in each case indicate the more dominant forces.

As the top drawing indicates, the leading (N) pole of the armature is repelled by the north poles of the two adjacent magnets. But, at the indicated position of the armature magnet, these two repulsive forces .(which obviously work against each other), are not identical; the stronger of the two forces (double dashed line) overpowers the other force and tends to move the armature to the left. This left movement is enhanced by the attraction force between the armature north pole and the stator south pole at the bottom of the space between the stator magnets.

But that's not all! Let's see what is happening simultaneously at the other end (S) of the armature magnet. The length of this magnet (about 3-1/8 inches) is chosen, in relation to the pairs of stator in magnets plus the space between them, so that once again the attraction/repulsion forces work to move the armature magnet to the left. In this case the armature pole (S) is attracted by the north surfaces of the adjacent stator magnets but, because of the critical armature dimensioning, more strongly by the magnet (double solid line) that tends to "pull" the armature to the left. It overpowers the lesser "drag" effect of the stator magnet to the right. Here also there is the added advantage of, in this case, repulsion force between the south pole of the armature and the south pole in the space between the stator magnets.

The importance of correct dimensioning of the armature magnet cannot be over-emphasized. If it is either too long or too short, it could achieve an undesirable equilibrium condition that would stall movement. The objective is to optimize all force conditions to develop the greatest possible off-balance condition, but always' in the same direction as the armature magnet moves along the row of stator magnets. However, if the armature is rotated 180 degrees and started at the opposite end of the track, it would behave in exactly the same manner except that it would, in this example, move from left to right. Also note that once the armature is in motion, it has momentum that helps carry it into the sphere of influence of the next pair of magnets where it gets another push and pull, and additional momentum.

Complex Forces

Some very complex magnetic forces are obviously at play in this deceptively simple magnetic system, and at this time it is impossible to develop a mathematical model of what actually occurs. However, computer analysis of the system, conducted by Professor William Harrison and his associates at Virginia Polytechnic Institute (Blacksburg, VA), provide vital feedback information that greatly helps in the effort to optimize these complex forces to achieve the most efficient possible operating design.

As Professor Harrison points out, in addition to the obvious interaction between the two poles of the armature magnet and the stator magnets, many other interactions are in play. The stator magnets affect each other and the support plate. Magnet distances and their strengths vary despite best efforts of manufacturers to exercise quality controls. In the assembly of the working model, there are inevitable differences between horizontal and vertical air spaces. All these interrelated factors must be optimized, which is why computer analysis in this refinement stage is vital. It's a kind of information feedback system. As changes are made in the physical design, fast dynamic measurements are made to see whether the expected results have actually been achieved. The 'new computer data is then used to develop new changes in the design of the experimental model. And so on, and on.

That very different magnetic conditions exist at the two ends of the armature is shown by the actual experimental data displayed in the table and associated graph. To obtain this information, the researchers first passed the probe of an instrument used to measure magnetic field strengths over the stator magnets and the intervening spaces. We shall call this the "Zero" level although there is a very tiny gap between the probe and the tops of the stator magnets. These measurements in effect indicate what each pole of the armature magnet "sees" below as it passes over. the stator magnets.

Next the probe is moved to a position just beneath one of the armature poles, at the top of the 3/8-inch armature-to-stator air gap. Another set of magnetic flux measurements is made. The procedure is repeated with the probe positioned just beneath the other armature pole.

Now "Instinct" might suggest, and correctly so, that the flux measurements at the top and bottom of the air gap will differ. But if "instinct" also suggests that these differences are pretty much the same at the two armature pole positions, you would be very much in error!

1050	1550	1000	1350
1000	950	925	1100
850	1700	875	1250
800	1900	775	1275
550	1400	600	1300
11,325 Gauss	19,375 Gauss	11,600 Gauss	17,100 Gauss

30,700 Gauss (Total) | 28,700 Gauss (Total)

2,000 Gauss (Difference)

First study the two tables that show actual flux density measurements. Note that in this particular experiment the total magnetic flux amounted to 30,700 Gauss (the unit of magnetic strength) when the probe was held at the "Zero" level under the north pole of the magnet, and a total of 28,700 Gauss when the probe was moved to the top of the 3/8-inch air gap. The difference between these total 'measurements is 2,000 Gauss.

Similar readings made at the air gap between the south pole of the armature and the stator magnets indicates a total flux at "Zero" level of 33,725 Gauss, and 24,700 Gauss at the top of the air gap. This time the difference is a much larger 9,025 Gauss, or four and one half times greater than for the north pole! Clearly, the magnetic force conditions are far from identical at the two ends of the armature magnet.

The middle five pairs of figures from each table hive been plotted in graphic form to make these differences more obvious. In the top "South Pole" graph the dashed line connects, the "Zero" level readings made over the stator magnets and over the intervening air spaces. Points along the solid line indicate comparable readings made with the probe just beneath the armature south pole. It is easy to see that there is an average 43% reduction of the attraction between the armature and stator magnets created by the air gap. Equally true, but perhaps not so obvious, is the fact that there is an average 36% increase of repulsion when the south pole of the armature passes over the spaces between the stator magnets. The percentage increase only seems smaller because it applies to a much smaller "Zero" level value.

The second graph shows that the changes are much less dramatic at the north pole of the armature. In this case there's an average 11.7% decrease of attraction over the spaces, and a 2.4% increase, of repulsion when the armature north pole passes over the stator magnets.

As you study the data, be sure to note that the columns are labeled differently. In the case of the north pole data, the stator magnet areas repulse the armature north pole while the spaces between the stator magnets attract. The conditions are exactly the opposite for the south pole of the armature magnet. When the south pole passes over a magnet, there is strong attraction; when it passes over a space, there is repulsion.

The Ultimate Motor

A motor based on Johnson's findings would be of extremely simple design compared to conventional motors. As shown in the diagrams developed from Johnson&rsquo;s patent literature, the stator/base unit would contain a ring of spaced magnets backed by a high magnetic permeability sleeve. Three arcuate armature magnets would be mounted in the armature which has a belt groove for power transmission. The armature is supported on ball bearings on a shaft that either screws or slides into the stator unit. Speed control and start/stop action would be achieved by the simple means of moving the armature toward and away from the stator section.

There is a noticeable pulsing action in the simple prototype units that may be undesirable in a practical motor. The movement can be smoothed, the inventor believes, by simply using two or more staggered armature magnets as shown in another drawing.

What&rsquo;s Ahead?

For inventor Howard Johnson and his permanent magnet power source there's bound to be plenty of controversy, certainly, but also progress. A 5000 watt electric generator powered by a permanent magnet motor is already on the way, and Johnson has firm licensing agreements with at least four companies at this writing.

Will we see permanent magnet motors in automobiles in the near future? Johnson wants nothing to do with Detroit at this time because, as he puts it: "It&rsquo;s too emotional - we&rsquo;d get smashed into the earth!" The inventor is equally reluctant to make predictions about other applications as well, mainly because he just wants time to perfect his ideas and, hopefully, get the scientific establishment to at least consider his unorthodox ideas with a more open mind.

For example, Johnson argues that the magnetic forces in a permanent magnet represent superconductance that is akin to phenomena normally associated only with extremely cold superconducting systems. He argues that a magnet is a room temperature superconducting system because the electron flow does not cease, and because this electron flow can be made to do work. And for those who pooh- pooh the idea that permanent magnets do work, Johnson has an answer: "You come along with a magnet and pick up a piece of iron, then some physicist says you didn't do any work because you used that magnet. But you moved a mass through a distance.

Right? That's work that requires energy. Or you can hold one magnet in the air indefinitely by positioning it over another magnet with like poles facing. The physicist will argue that because it involves magnetic repulsion, no work is done. Yet if you support the same object with air, they will agree in a minute that work is done!"

There's no doubt in Johnson's mind that he has succeeded in extracting usable energy from the atoms of permanent magnets. But does that imply that the electron spins and associated phenomena that he thinks provide this power will eventually be used up? Johnson makes no pretense of knowing the answer: I didn't start the electron spins, and I don't know any way to stop them - do you? They may eventually stop, but that is not my problem."

Johnson still has many practical problems to solve to perfect his invention. But his greater challenge may be to win general acceptance of his ideas by an obviously nervous scientific community in which many physicists remain compulsive about defending the law of Conservation of Energy without ever wondering whether that "law" really needs defending.

The dilemma facing Johnson is not really his dilemma but rather that of other scientists who have observed his prototypes. The devices obviously do work. But the textbooks say it shouldn&rsquo;t work. And all that Johnson is really saying to the scientific community is this: here is a phenomenon which seems to contradict some of our traditional beliefs. For all our sakes let&rsquo;s not dismiss it outright but take the time to understand the complex forces at work here.

The Permanent Magnet Motor

by
Howard R. Johnson
&
William P. Harrison, Jr.

(Engineering Fundamentals Division, Virginia Polytechnic Institute and State University, Blacksburg, VA)

Presented at the UNITAR (UN Institute for Training & Research) Conference on Long-Term Energy Resource, Montreal, Canada, November 26-December 7, 1979.

I. Introductory remarks (by Mr. Johnson)

Today when energy is so expensive, it is not hard to drum up interst for most any avenue that offers a breath of hope or a way of escape, but this was not necessarily so in 1942. We were somewhat satisfied and convinced that we had the main sources of energy in view. So it took a pure act of faith to try to develop a new un-named source.

It took faith to spend time on it. It took faith to spend money on it. And it took faith to consider facing the opposition later when I made my work known and faced all the *status quo* people.

So, in 1942 using the Bohr model of the atom, and knowing that unpaired electron spins created a permanent magnet dipole, I kept wondering why we couldn't use these fields to drive something. I was sure that the magnetic effect of the spins was similar enough to the field of a current in a wire to do the same thing. I had no knowledge of electron spins stopping and knew no method that I could exert to stop them, so I decided to try to work out a method to use them.

At the same time there were no good hard magnetic materials that I knew of, materials that could be opposed with strong magnetic fields and not be demagnetized enough to damage them. Not only that, they would not give the thrust that I desired.

Having a chemical background, I thought it would be nice to use the best magnetic materials I could find in combination with an interstitial material that was highly diamagnetic to force the electron spin to stay in place.

The U.S. Navy later made such a compound using bismuth and good magnetic materials, but the internal coercive forces were so great that this strong magnet would fall apart if not encased in glass. It was also expensive.

So I kept checking magnetic materials while I worked on designs that I thought should be implemented. It was a quiet, sometimes lonely job over the years, for I didn't share my plans with my associates. My self-imposed security would not permit it, and I knew of few people who would be interested anyway.

In the fifties, as ceramic magnets became better and harder, and long-field metal magnets appeared on the scene, I began to freeze some designs and to have magnets custom made to fit them.

It was about this time that I mentioned the fact that just as I believed electron spins made permanent magnets, I also believed that they were responsible for the 60° angles in the structure of snowflakes giving the six-spoked wheel, the six-sided spokes, etc. The dean of the school where I was teaching said, "Maybe so" and ask me if I knew that snowflakes were mentioned in the Bible as being important. I told him, "No, I didn't know that," but I looked it up. It said: "Hast thou entered into the treasures of the snow? Or hast thou seen the treasures of the hail? Which I have reserved against the time of trouble, against the day of battle and war."

My comment was, "Well, maybe this is more important than I thought." So I went ahead and worked on it another ten years.

I went to the Library of Congress and looked up snowflakes. I found a wonderful book there by Dr. Bentley of New Hampshire. He has spend many years making these studies, and he had learned a lot, as well as turning out one of the world's most beautiful books. He had found that snowflakes have gas pockets oriented on 60° angles and that the gas has a higher percentage of oxygen than air. That's one reason why snow water rusts so well. This higher concentration of oxygen also interested me because oxygen is more attracted to a magnetic field than other gases.

Finally, using the best ceramic magnets I could find and the best metal magnets, I worked out a scheme for a linear motor. The stator would be laid out as if it were unwound from around a motor. The parts of the armature would ride just above the stator and have the same beveled angular orientations I have just mentioned.

Dies were made for the curved armature magnets, and an order was placed for these shapes, despite the objections of magnet manufacturers who said it was a bad design. They didn't know what it was for, but they were sure it was a bad design. They wanted to make horseshoe magnets. They even begged me to content myself with half an order. I did not agree --- and once again you have that little matter of faith; faith to try to implement a new theory; faith to spend your own limited funds when you have a a family and other financial responsibilities staring you in the face; faith to buck the recognized authorities and manufacturers in the field; faith to believe that your work is good and that some day, despite all the hazards, you will apply for and receive patent rights in your own country and perhaps throughout the rest of the world; and finally, faith that you can resist being smashed into dust by industrial giants and/or being robbed by others who know only how to steal.

Believe it or not, my first motor assembly showed about two pounds of thrust. The little toy car on which I fastened the armature magnets for support ran in both directions over the stator, showing that the focusing and timing of the interactions was not too bad.

This was the first light at the end of a rather dark tunnel I had been traveling for many years. I breathed a real sign of relief as my young son played with this "new toy," and was able to operate it as easily as I could.

After much testing of linear and circular designs, and looking for an attorney for years suited to securing a patent on the new theoretical work, I was led to Dunkan Beaman of Beaman & Beamon in Jackson, Michigan. It took some time to prepare the patent. The attorney built some models himself to check certain parameters. Finally, we entered the case in the patent office expecting a lot of opposition. We were correct. We got it. But again, faith saved the day as we battled for many years to gain a rather complete victory.

Now the work requires different kinds of faith: faith in those who have taken cut licenses and who will license; faith to continue the research to replace scarce materials in the magnets; and faith that this work will continue to progress and that it will eventually fulfill its goal.

For a number of reasons, the permanent magnet motor has not received much consideration. In fact, nothing too radical has been done since Faraday took some very crude materials and showed the world that it was possible to make a motor. This work of his largely influenced the thinking of Clerk Maxwell and others who followed.

Today, the two greatest obstacles to using a permanent magnet motor are, first, the belief that it violates the conservation of energy law; and, secondly, that the magnetic fields of attraction and repulsion decrease according to the inverse square law then the air gap is increased.

In fact, both contentions are quite wrong because they are based on wrong considerations.

The permanent magnet is a long time energy source. This has been shown for many years in the rating of magnets as high or low energy sources for many applications over long usage.

A loudspeaker composed entirely of electromagnets would be unreal in size and energy consumption. Yet, despite examples of this type, many hesitate to apply the same principles to motors and extend them even further by using permanent magnets for both the stator and armature.

The elements of all electric and permanent magnet motors are similar. A field imbalance must be created, the fields must be focused and timed, and magnetic leakage must be controlled.

In the wound motor, brushes and contact rings give the timing, the size and shape of the wound fields and poles gives the focusing, and the motor case and kind of iron used help to limit the leakage.

In our permanent magnet motors the timing is built into the motors by the size, shape, and spacing of the magnets in the stator and armature. The focusing is controlled by the shape of the magnets, pole length, and the width of the air gap. This air gap, through which magnets oppose and attract each other, is a rare phenomenon. Usually when a magnetic air gap is increased, the field decreases inversely as the square.

When the air gap of the permanent magnet motor is increased, a curious but definite change takes place. There is a large decrease in the reading at south pole of the armature and an increase in the reading at the north pole. Thus, a Hall-effect sensing probe will give a higher gauss reading at the north pole and a decreasing count at the south pole. This helps explain why the thrust is better with a larger air gap than a smaller one. The attracting field is minimized and will not produce a locking force, while the repulsion of the crescent magnet is great enough to generate a thrust vector component that will drive the armature.

As I tried to explain in the patent, I believe that the permanent magnet is the first room temperature super conductor. In fact, I believe that super conductors are simply large wound magnets. The current in a super conductor is not initiated by a strong emf, such as a battery, but is instead actually induced into existence by a magnetic field. Then, in order to determine how much current may be flowing in the super conductor coil, we measure its magnetic field. This appears to be something like going out the door and coming back in the window.

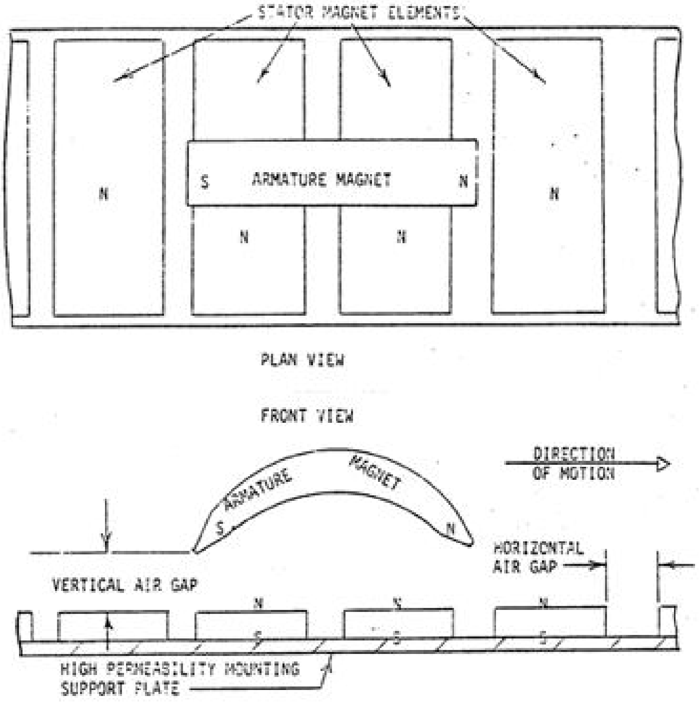
Another rather unique feature of super conductors is the fact that their magnetic lines of force experience a change in direction. No longer do these lines flow at right angles to the conductor, but they now exist parallel to the conductor. Theoretically, the heavy conductor currents exist in the fine filaments of niobium within each small wire of niobium tin from which such super conductors are made. Isn't it interesting that the finer the wire the less the resistance until eventually there is no resistance at all?

II. Theoretical Analysis (presented by William P. Harrison, Jr.)

1. Introduction

Despite the fact that the linear version of the permanent magnet motor (Johnson, 1979) may appear conceptually simple (see Fig. 1), the complex interactions of the fields alone place it in a class with other quite sophisticated motive systems.

Figure 1: Partial Front and Plan Views of a Linear Model of the Howard Johnson Permanent Magnet Motor



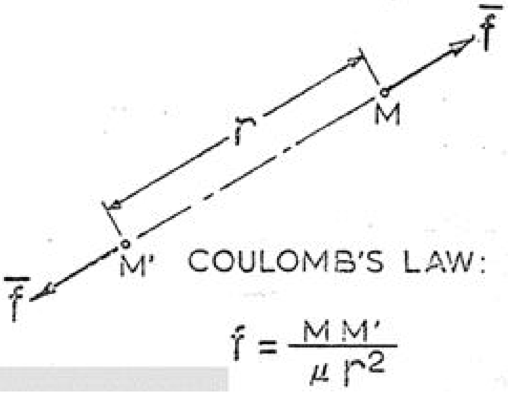
Many parameters play an important part in making possible the successful design of a permanent magnet motor. A number of these variables relate directly to the geometry of the system and its components. Mathematical models for both the linear and circular versions of Mr. Johnson's motors are presently under development, and include such controllable parameters as stator-to-armature air gap, stator element air gap spacing, armature pole length, stator magnet dimensions, magnet material variations, magnetic permeability and geometry of backing metals, and multiple armature couplings, to mention only a few. However, much of the early work involved quit simple mathematical investigations, and even at this level some remarkable revelations resulted. Also, as often is true with simple models, considerable insight into the mechanisms that might prove predominant was gained. Therefore, it is our intention to share with you some of those early analytical investigations and findings.

Even though Coulomb's Law, embodying the inverse square relationship as it does, may yet prove suspect, it nevertheless provides an exceedingly simple yet viable form upon which to base an elementary model of the linear version of the permanent magnet motor. Describing the interaction between two magnetic monopoles, Coulomb's Law in vector form is recalled as

(1) $$\bar{f} = \frac{\overline{MM'}}{ur^2}$$

where M and M' are the pole strengths (positive if north, negative if south), *u* [mu] is the permeability of the medium in which the poles are located, *r* is the straight-line separation distance between the two poles, and *f* [*f* with line over top] is the vector of force (see Fig. 2) acting at each pole (positive in magnitude for repulsion and negative for attraction).

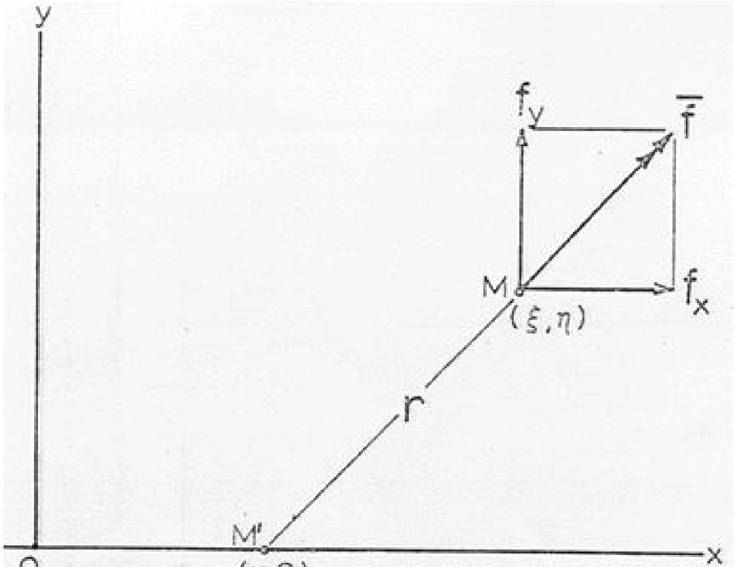
Figure 2: Coulomb's Law



The vector nature of Eq. (1), the fact that f's line of action is colinear with the straight-line distance *r* between poles, its superposition properties when applied to multiple poles, and its restriction to static systems fixes in space are all well known conditions on Eq. (1). We will use the superposition property of Eq. (1) to extend its application to a spatial domain containing many more poles than the two shown in Fig. 2. However, Eq. (1) will first be resolved into scalar components so that analytical expressions can be more easily developed.

Our analysis will be two-dimensional and coplanar, restricted to the vertical x-y plane. It should be noted that the horizontal stator "track" of H.R. Johnson's linear model comprises a plurality of flat magnets, rectangular in cross section, each having an aspect ratio (length-to-thickness ratio) of 16. This high value contributes to the two-dimensional nature of the model and helps to minimize and effects in the z direction. Thus there is some justification for a two-dimensional analysis, at least in the case of the linear model we are considering here.

Figure 3: Positional Locations of Two Opposing North monopoles in X-Y Space ~



As shown in Fig. 3, we consider first a north pole of strength M located at coordinates (*E* [epsilon], *n* [nu]) with a second north pole of strength M', located on the x-axis at (x,0). Force *f*, acting on the monopole at (*E*,*n*), when resolved into its horizontal and vertical components yields, respectively,

$$f_x = \frac{MM'(\xi - y)}{\mu[(\xi - x)^2 + \eta^2]^{3/2}}$$

(2)

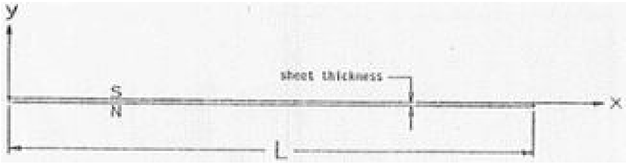
and

$$f_y = \frac{MM'\eta}{\mu[(\xi - x)^2 + \eta^2]^{3/2}}$$

(3)

2. The Attractive Sheet

Figure 4: Spatial Orientation of Thin, Magnetized Sheet having high aspect ratio and with S side face up



To illustrate some of the assumptions and extensions of Coulomb&rsquo;s Law that will be made, the simple example of a magnetic sheet lying along the x-axis will be considered first (see Fig. 4). The sheet, of finite length L, is a permanent magnet magnetized across its y-direction thickness and having a high aspect ratio (to eliminate z-direction edge effects). The south-pole face will be oriented up, with north facing downward on the underside of the sheet. Underside effects will be ignored as though the sheet represented a continuous distribution of only south monopoles along the x-axis. To incorporate such distributions into Eq. (1) we replace M&rsquo; with the differential dM&rsquo; and introduce the function B(x) so that

(4) dM&rsquo; = B(x) dx

Then the magnitude of the total force vector, F, acting on an isolated north monopole of strength M situated somewhere within the upper half of the x-y plane, becomes

$$F = \frac{ML}{\mu}\int_0 \frac{B(x)}{r^2}\,dx$$

(5)

where x is the ratio x/L. Assuming that the magnetic density along the sheet can be represented by the southern constant *-B*, and neglecting end effects at x = 0 and x = L, Eq (5) reduces to

$$F = -\mathcal{F}\int_0^1 \frac{1}{\rho^2}\, dx$$

(6)

where

$$\mathcal{F} \equiv \left|\frac{MM'}{\mu L^2}\right|$$

(7)

the strength parameter M&rsquo; having been determined by integrating Eq (4) over the sheet length L, and *p* is the ratio r/L.

Figure 5: North Monopole Positioned Symmetrically above the center of a magnetized, attracting sheet

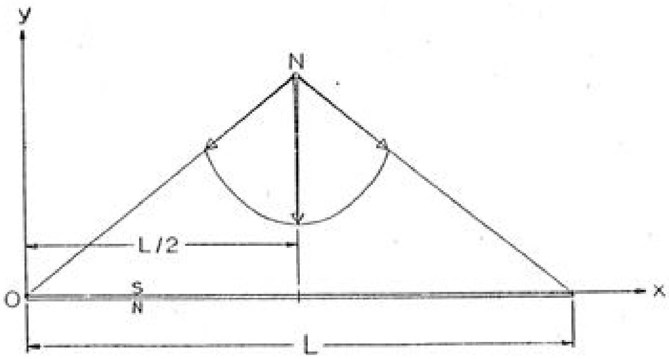


Figure 6: Force Imbalance Acting on a North Monopole above a mangetized sheet tending to restore the pole to sheet center

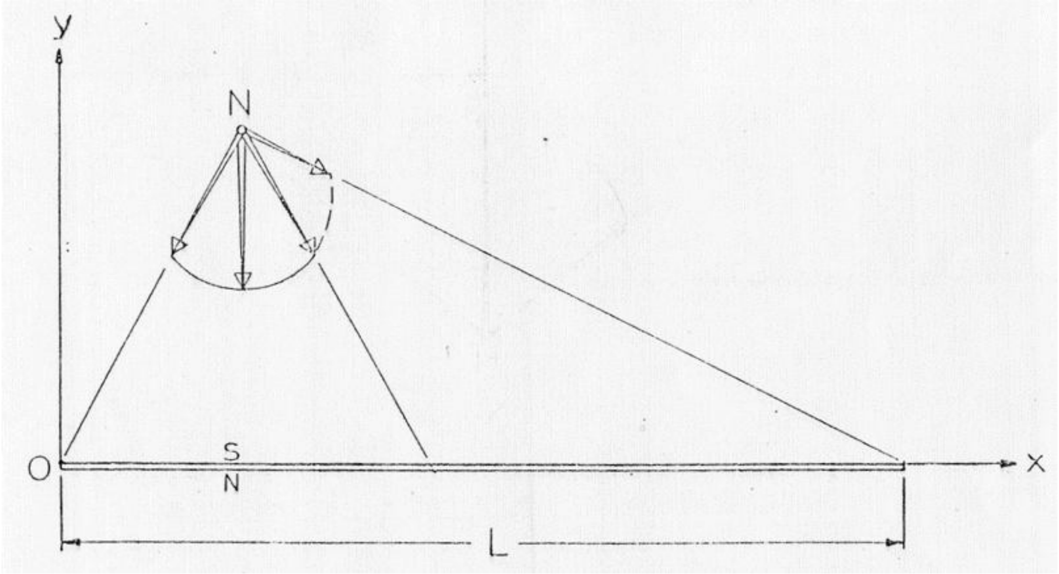


If the north monopole is placed directly above the center of the sheet, at coordinates (*E, n*), with *E* = L/2 and the vertical air-gap separation distance n taken as arbitrary, the symmetrical distribution of incremental force vectors acting at (*E,n*) will appear as shown in Fig. 5. Note that a shift of the north monopole to the left results in a force imbalance which tends to pull the pole back to the right, as shown in Fig. 6. So considering now only the x-component of F, similar to Eq (2) we write

(8) $$F_X = \mathcal{F}\int_0^1 \frac{X - x}{[(X - x)^2 + Y^2]^{3/2}}\, dx$$

where X and Y are the dimensionless ratios

(9) $$X \equiv \xi/L$$

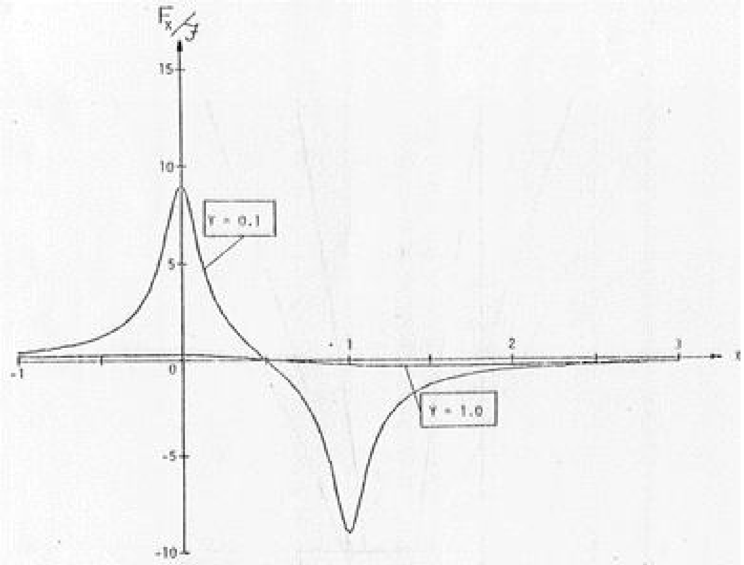
and

(10) $$Y \equiv \eta/L$$

For any fixed position (X,Y) of the north monopole in the upper half plane, Eq (8) can be integrated to give

(11) $$\frac{F_X}{\mathcal{F}} = \frac{1}{\sqrt{X^2 + Y^2}} - \frac{1}{\sqrt{(X - 1)^2 + Y^2}}$$

Figure 7: X-Direction Distribution of the X-Component of attractive force exerted on a north monopole by a thin, magnetized sheet



This ratio is shown in Fig (7) as a continuous function of X locations with Y treated parametrically. The Y = 1 curve represents the field influence on the north monopole situated at a constant air-gap separation (*n* = L) quite some vertical distance above the sheet; whereas at Y = 0.1 the monopole is located much closer to the x axis. Reversal of the force component through its zero value at mid-sheet (X = ½) is clearly shown.

In order to trace some trajectories through this field, we now observe that the y-component of force *F* will be

$$\frac{F_Y}{\mathcal{J}} = -\frac{1}{Y}\left[\frac{X}{\sqrt{X^2 + Y^2}} - \frac{X - 1}{\sqrt{(X - 1)^2 + Y^2}}\right] .$$

(12)

This function is shown in Fig (8) with a Y value of 0.20

Figure 8: [Missing]

In dimensionless form the equations of motion for trajectory paths of the monopole above the sheet in planar X-Y space become

(13) $$\frac{d^2X}{d\tau^2} = E(r_X)_{mag}$$

and

(14) $$\frac{d^2Y}{d\tau^2} = E(r_Y)_{mag} - G$$

where

(15) $$\tau \equiv \frac{t}{T}$$

(16) $$G \equiv \frac{gT^2}{L}$$

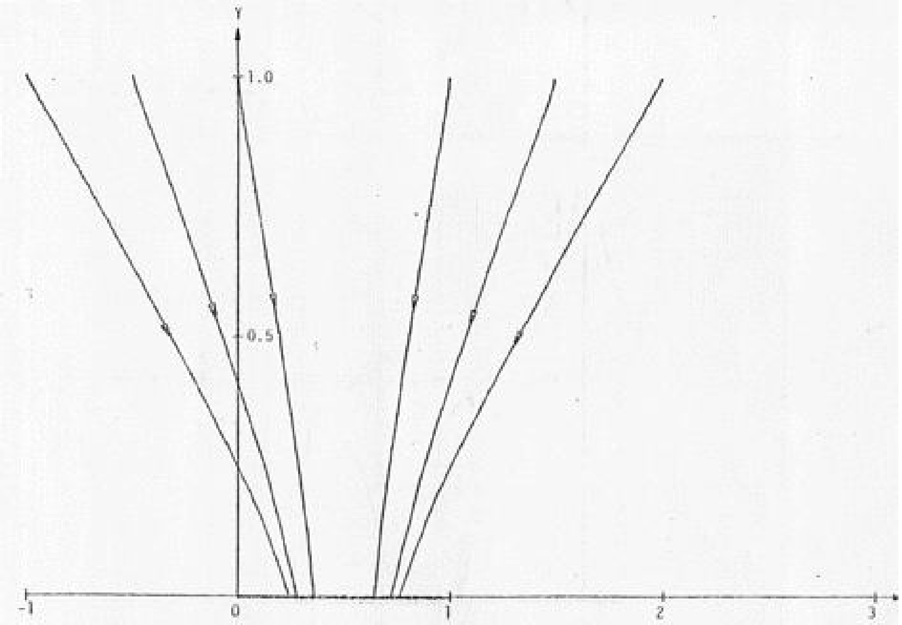
and

(17) $$E \equiv \frac{G}{(W/\mathcal{F})}$$

In these expression *t* is real time and *T* is simply a time constant chosen arbitrarily. As previously noted, *L* is the length of the sheet; whereas, *g* is the gravitational acceleration constant and *W* is the downward weight force of the moving monopole above the sheet. For magnetic force terms $(r_x)_{mag}$ and $(r_y)_{mag}$ we substitute directly Eq (11) and Eq (12), respectively.

Several of the trajectories resulting from the integration of Eq (13) and Eq (14) are shown in Fig.9. They all exhibit the expected behavior. As already implied in the discussion of Fig. 7, the function $(r_x)_{mag}$ given by Eq (11) has a stable point of equilibrium at X = ½ and therefore drives the free-falling monopole towards the sheet center, regardless of the initial drop-point location. The function $(r_y)_{mag}$ from Eq (12) is equally persuasive in pulling the monopole down towards the sheet itself, and manifests that attraction quite pervasively throughout the integration of Eq (14), even when the *G* term may be omitted (as it was in the trajectories of Fig. 9). Actually, the computer integration procedure will not carry the monopole all the way to surface contact with the sheet at Y = 0 because of the infinite condition which exists there as reflected by Eq (12). Thus, tailings of these trajectories (Fig 9) have been completed by manually overriding the plotter.

Figure 9: Trajectories of a North Monopole in an attractive field generated by the thin, magnetized sheet lying in the X-interval 0-1



As we would anticipate in working with this type of central field, where *B* in Eq (4) is a simple constant, the field is conservative with curl of F vanishing. Also, the reverse symmetry of $(r_x)_{mag}$ about X = ½, as seen in Fig. 7, confirms that the energy integral for this function will vanish without any appropriate limit pairs of X.

3. The Repulsive Sheet

By substituting +*B* instead of -*B* for *B* in Eq (4), the sheet of length L lying along the x-axis becomes repulsive, with its northern face directed upward, opposing the north monopole above it at location (*E,n*). Of course the sign in Eq (6) becomes positive and the functions $(r_x)_{mag}$ and $(r_y)_{mag}$ reverse their behavior accordingly, as illustrated in Fig. 10. Again $(r_x)_{mag}$ will have an equilibrium point at X = ½, but now it is destabilizing. As a consequence, resulting trajectories for the north monopole are much more interesting in this case than they were with the attractive sheet. Several paths are shown in Fig 11 with different values used for the W/Ɉ trajectory in Eq (17). Parameter G was included, and in each example the trajectories commenced at (0.9, 0.2) with zero initial velocity.

Figure 10: X-Direction Distributions of $(r_x)_{mag}$ and $(r_y)_{mag}$ for the repulsive field of a thin, magnetized sheet acting on a moving north monopole

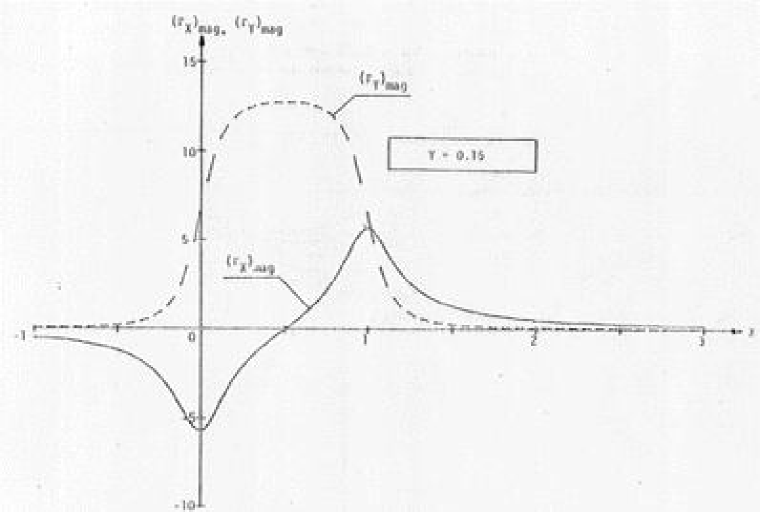


Figure 11: Trajectories of a North Monopole in a repulsive field generated by a thin, magnetized sheet lying in the X-interval 0-1

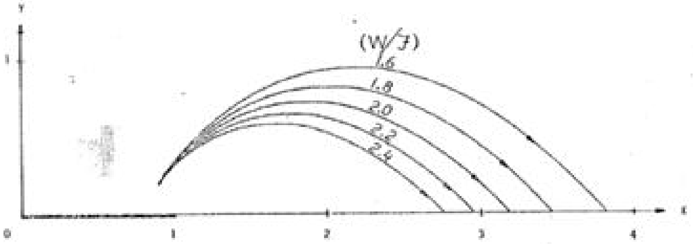

The attractive and repulsive sheet results are easily demonstrated since rubberized flexible sheet magnets are commercially available, such as those sold by the Permag Corp. of Jamaica, NY. It may also be interesting to note that with slight modifications this first simple analytical sheet model can be used to gain some insight into operation of the so-called "magnetic Wankel" reported on by Scott (1979).

Figure 12: Pole Strength Influence Factor, M', as a cosine function of linear displacement distance, x

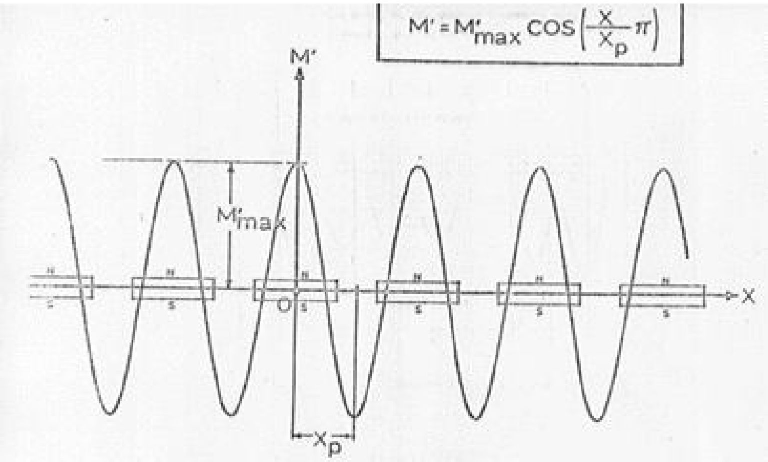

Figure 13: Experimentally Detemined Magnetic Flux Density, B, along a linear model of the Johnson permanent magnet motor

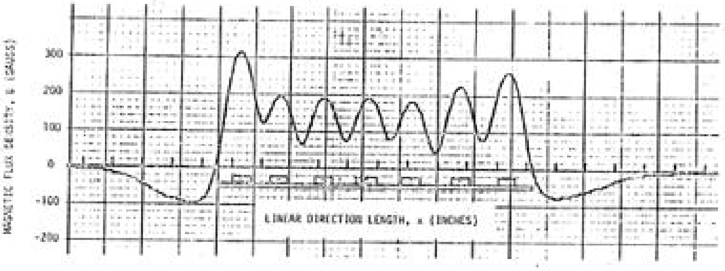


4. The Sinusoidal Model

The first paper (Harrison, 1979) relating, indirectly, to any mathematical analysis of the permanent magnet motor adopted a cosine function (Fig 12) to simulate the distribution of influence parameter M&rsquo; generated by the flat stator track of Mr Johnson&rsquo;s linear model. An experimentally determined distribution, shown in Fig 13, was obtained by moving a Hall-effect probe over the stator track of one of Mr Johnson&rsquo;s early linear models having seven flat ceramic magnet elements. The figure shown was produced by a plotter connected directly to the monitor computer controlling positioning of the Hall probe and processing its output signal. Ordinate values on the graph are magnetic flux density in gauss measured relative to a predetermined background value. These direct-reading experimental results suggest that the function

$$B(x) = \beta \cos(2\pi x/x_p) \tag{18}$$

substituted into Eq (4) should prove interesting to pursue as a more challenging test of what might be gleaned from this simple Coulomb model we have been discussing. It should be noted that one of the important differences between the function (18) and that shown in Fig 12 is that in Eq (18) the period length parameter xp is double that shown in Figure 12.

Using Eq (18), the total force magnitude expression Eq (5) becomes

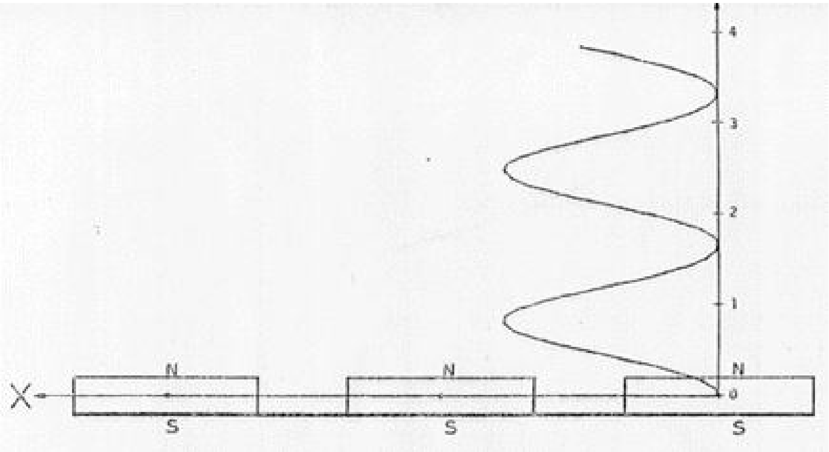
$$(\Gamma_X)_{mag} \equiv \frac{F_X}{\mathcal{J}} = \int_0^1 \frac{(X - x)\cos(2\pi x/x_p)}{[(X - x)^2 + Y^2]^{3/2}}\, dx \tag{19}$$

where a total track length distance of L has been used to form the dimensionless ratios p = r/L, x = x/L, and xp = xp/L. Also, if Eq (7) is used for $\mathcal{J}$ in Eq (19), then in that expression one must substitute the product BL for M&rsquo;.

Now we plan to hold Y constant while investigating linear motion of the monopole along this track in the X-direction only. So we need consider only the X-component of $\underline{F}$ from Eq (19) which yields

$$(\Gamma_X)_{mag} \equiv \frac{F_X}{\mathcal{J}} = \int_0^1 \frac{(X - x)\cos(2\pi x/x_p)}{[(X - x)^2 + Y^2]^{3/2}}\, dx \tag{20}$$

Figure 14: Oscillatory Path of a North Monopole restrained to x-direction motion over a three-element linear stator assembly



With this expression substituted into Eq (13), integration becomes straightforward and yields the typical oscillatory type of trajectory path shown in Fig 14. As Mr Johnson has brought out, the focusing armature magnet of his linear model will start at either end of the stator track simply by insuring that the north end of this bipoled crescent is leading the south (see Fig. 1). So, in Fig. 14, we are showing the X-direction motion from right to left instead of from left to right as in our previous examples. Also, by simply rotating the figure clockwise through 90 degrees, it becomes easy to follow the behavior of dimensionless velocity, V_X, in Fig 11, since Vx is defined as

$$V_X = \frac{dX}{d\tau} \tag{21}$$

It will be noted in Fig 14 that the north monopole has been allowed to self-start its motion at the origin with V_X initially zero.

We now discuss out final adjustment which proved to be an exciting revelation at the time it was first investigated several months ago. Johnson (1979, col. 5, line 39) states that the horizontal air-gap spacing between the magnet elements which the stator track comprises should vary slightly from normal in order to smooth out movement of the armature. Introducing this type of variation into a two-dimensional model, provided the charge is nonuniform, would certainly transform the field from conservative to nonconservative. It should by now be apparent that only a nonconservative model has any chance at all of even partially explaining the phenomena of the permanent magnet motor.

With these thoughts in mind, an attempt was made to drive the armature monopole of Fig 14 on to the second stator magnet and beyond by varying the horizontal gap parameter xp during the integration process (i.e., during the motion). The results are shown in Fig 15. It was found that through small variations in *xp* in Eq (20), as the monopole advanced along its trajectory path from one X position to another, sufficient control over the moving pole could be exercised to carry it over the full length of the stator and beyond.

Permanent Magnet Motor

(April 24, 1979)

Howard R. Johnson

Abstract --- The invention is directed to the method of utilizing the unpaired electron spins in ferro magnetic and other materials as a source of magnetic fields for producing power without any electron flow as occurs in normal conductors, and to permanent magnet motors for utilizing this method to produce a power source. In the practice of the invention the unpaired electron spins occurring within permanent magnets are utilized to produce a motive power source solely through the superconducting characteristics of a permanent magnet and the magnetic flux created by the magnets are controlled and concentrated to orient the magnetic forces generated in such a manner to do useful continuous work, such as the displacement of a rotor with respect to a stator. The timing and orientation of magnetic forces at the rotor and stator components produced by permanent magnets to produce a motor is accomplished with the proper geometrical relationship of these components.

Description

FIELD OF THE INVENTION

The invention pertains to the field of permanent magnet motor devices solely using the magnetic fields created thereby to product motive power.

BACKGROUND OF THE INVENTION

Conventional electric motors employ magnetic forces to produce either rotative or linear motion. Electric motors operate on the principle that when a conductor is located in a magnetic field which carries current a magnetic force is exerted upon it.

Normally, in a conventional electric motor, the rotor, or stator, or both, are so wired that magnetic fields created by electromagnetics may employ attraction, repulsion, or both types of magnetic forces, to impose a force upon the armature to cause rotation, or to cause the armature to be displaced in a linear path. Conventional electric motors may employ permanent magnets either in the armature or stator components, but in the art heretofore known the use of permanent magnets in either the stator or armature require the creation of an electromagnetic field to act upon the field produced by the permanent magnets, and switching means are employed to control the energization of the electromagnets and the orientation of the magnetic fields, to produce the motive power.

It is my belief that the full potential of magnetic forces existing in permanent magnets has not been recognized or utilized because of incomplete information and theory with respect to the atomic motion occurring within a permanent magnet. It is my belief that a presently unnamed atomic particle is associated with the electron movement of a superconducting electromagnet and the lossless current flow of Amperian currents in permanent magnets. The unpaired electron flow is similar in both situations. This small particle is believed to be opposite in charge and to be located at right angles to the moving electron, and the particle would be very small as to penetrate all known elements, in their various states as well as their known compounds, unless they have unpaired electrons which capture these particles as they endeavor to pass therethrough.

Ferro electrons differ from those of most elements in that they are unpaired, and being unpaired they spin around the nucleus in such a way that they respond to magnetic fields as well as creating one themselves. If they were paired, their magnetic fields would cancel out. However, being unpaired they create a measurable magnetic field if their spins have been oriented in one direction. The spins are at right angles to their magnetic fields.

In niobium superconductors at a critical state, the magnetic lines of force cease to be at right angles. This change must be due to establishing the required conditions for unpaired electronic spins instead of electron flow in the conductor, and the fact that very powerful electromagnets that can be formed with superconductors illustrates the tremendous advantage of producing the magnetic field by unpaired electron spins rather than conventional electron flow.

In a superconducting metal, wherein the electrical resistance becomes greater in the metal than the proton resistance, the flow turns to electron spins and the positive particles flow parallel in the metal in the manner occurring in a permanent magnet where a powerful flow of magnetic positive particles or magnetic flux causes the unpaired electrons to spin at right angles. Under cryogenic superconduction conditions the freezing of the crystals in place makes it possible for the spins to continue, and in a permanent magnet the grain orientation of the magnetized material results in the spins permitting them to continue and for the flux to flow parallel to the metal.

In a superconductor, at first the electron is flowing and the positive particle is spinning; later, when critical, the reverse occurs, i.e., the electron is spinning and the positive particle is flowing at right angles. These positive particles will thread or work their way through the electron spins present in the metal.

In a sense, a permanent magnet may be considered the only room temperature superconductor. It is a superconductor because the electron flow does not cease, and this electron flow can be made to do work because of the magnetic field it supplies.

Previously, this source of power has not been used because it was not possible to modify the electron flow to accomplish the switching functions of the magnetic field. Such switching functions are common in a conventional electric motor where electrical current is employed to align the much greater electron current in the iron pole pieces and concentrate the magnetic field at the proper places to give the thrust necessary to move the motor armature. In a conventional electric motor, switching is accomplished by the use of brushes, commutators, alternating current, or other known means.

In order to accomplish the switching function in a permanent magnet motor, it is necessary to shield the magnetic leakage so that it will not appear as too great a loss factor at the wrong places. The best method to accomplish this is to use the superconductor of magnetic flux and concentrate it to the place where it will be the most effective. Timing and switching can be achieved in a permanent magnet motor by concentrating the flux and using the proper geometry of the motor rotor and stator to make most effective use of the magnetic fields generated by the electron spins. By the proper combination of materials, geometry and magnetic concentration, it is possible to achieve a mechanical advantage of high ratio, greater than 100 to 1, capable of producing a continuous motive force.

To my knowledge, previous work done with permanent magnets, and motive devices utilizing permanent magnets, have not achieved the result desired in the practice of the inventive concept, and it is with the proper combination of materials, geometry and magnetic concentration that the presence of the magnetic spins within a permanent magnet may be utilized as a motive force.

SUMMARY OF THE INVENTION

It is an object of the invention to utilize the magnetic spinning phenomenon of unpaired electrons occurring in ferro magnetic material to produce the movement of a mass in a unidirectional manner as to permit a motor to be driven solely by magnetic forces as occurring within permanent magnets. In the practice of the inventive concepts, motors of either linear or rotative types may be produced.

It is an object of the invention to provide the proper combination of materials, geometry and magnetic concentration to utilize the force generated by unpaired electron spins existing in permanent magnets to power a motor. Whether the motor constitutes a linear embodiment, or a rotary embodiment, in each instance the "stator" may consist of a plurality of permanent magnets fixed relative to each other in space relationship to define a track, linear in form in the linear embodiment, and circular in form in the rotary embodiment. An armature magnet is located in spaced relationship to such track defined by the stator magnets wherein an air gap exists therebetween. The length of the armature magnet is defined by poles of opposite polarity, and the length of the armature magnet is disposed relative to the track defined by the stator magnets in the direction of the path of movement of the armature magnet as displaced by the magnetic forces.

The stator magnets are so mounted that poles of like polarity are disposed toward the armature magnet and as the armature magnet has poles which are both attracted to and repelled by the adjacent pole of the stator magnets, both attraction and repulsion forces act upon the armature magnet to produce the relative displacement between the armature and stator magnets.

The continuing motive force producing displacement between the armature and stator magnets results from the relationship of the length of the armature magnet in the direction of its path of movement as related to the dimension of the stator magnets, and the spacing therebetween, in the direction of the path of armature magnet movement. This ratio of magnet and magnet spacings, and with an acceptable air gap spacing between the stator and armature magnets, will produce a resultant force upon the armature magnet which displaces the armature magnet across the stator magnet along its path of movement.

In the practice of the invention movement of the armature magnet relative to the stator magnets results from a combination of attraction and repulsion forces existing between the stator and armature magnets. By concentrating the magnetic fields of the stator and armature magnets the motive force imposed upon the armature magnet is intensified, and in the disclosed embodiments such magnetic field concentration means are disclosed.

The disclosed magnetic field concentrating means comprise a plate of high magnetic field permeability disposed adjacent one side of the stator magnets in substantial engagement therewith. This high permeability material is thus disposed adjacent poles of like polarity of the stator magnets. The magnetic field of the armature magnet may be concentrated and directionally oriented by bowing the armature magnet, and the magnetic field may further be concentrated by shaping the pole ends of the armature magnet to concentrate the magnet field at a relatively limited surface at the armature magnet pole ends.

Preferably, a plurality of armature magnets are used which are staggered with respect to each other in the direction of armature magnet movement. Such an offsetting or staggering of the armature magnets distributes the impulses of force imposed upon the armature magnets and results in a smoother application of forces to the armature magnet producing a smoother and more uniform movement of the armature component.

In the rotary embodiment of the permanent magnet motor of the invention the stator magnets are arranged in a circle, and the armature magnets rotate about the stator magnets. Means are disclosed for producing relative axial displacement between the stator and armature magnets to adjust the axial alignment thereof, and thereby regulate the magnitude of the magnetic forces being imposed upon the armature magnets. In this manner the speed of rotation of the rotary embodiment may be regulated.

BRIEF DESCRIPTION OF THE DRAWINGS

The aforementioned objects and advantages of the invention will be appreciated from the following description and accompanying drawings wherein:

FIG. 1 is a schematic view of electron flow in a superconductor indicating the unpaired electron spins,

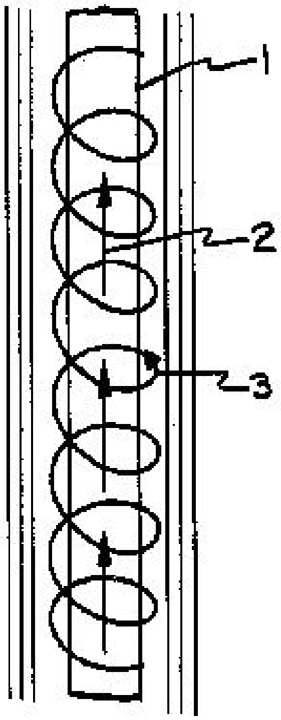

FIG. 1

FIG. 2 is a cross-sectional view of a superconductor under a critical state illustrating the electron spins,

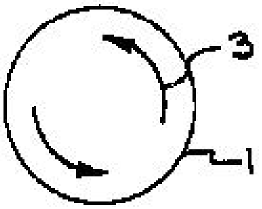

FIG. 2

FIG. 3 is a view of a permanent magnet illustrating the flux movement therethrough,

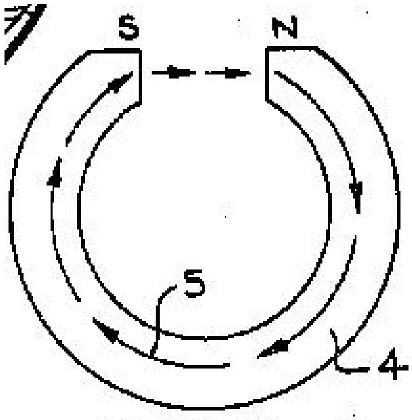

FIG. 3

FIG. 4 is a cross-sectional view illustrating the diameter of the magnet of FIG. 3,

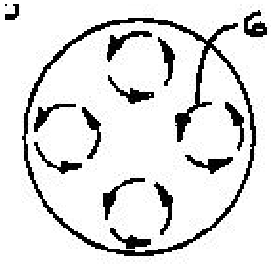

FIG. 4

FIG. 5 is an elevational representation of a linear motor embodiment of the permanent magnet motor of the invention illustrating one position of the armature magnet relative to the stator magnets, and indicating the magnetic forces imposed upon the armature magnet,

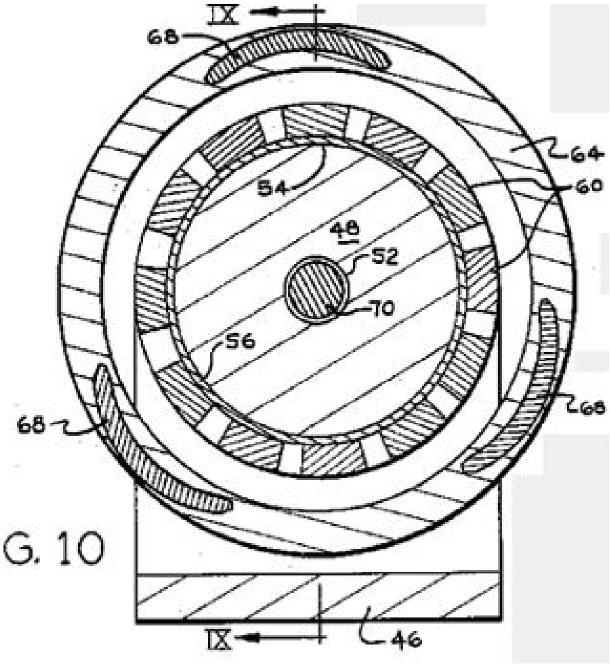

FIG. 10

DESCRIPTION OF THE PREFERRED EMBODIMENTS

In order to better understand the theory of the inventive concept, reference is made to FIGS. 1 through 4. In FIG. 1 a superconductor 1 is illustrated having a positive particle flow as represented by arrow 2, the unpaired electrons of the ferrous conducting material 1 spin at right angles to the proton flow in the conductor as represented by the spiral line and arrow 3. In accord with the theory of the invention the spinning of the ferrous unpaired electrons results from the atomic structure of ferrous materials and this spinning atomic particle is believed to be opposite in charge and located at right angles to the moving electrons. It is assumed to be very small in size capable of penetrating other elements and their compounds unless they have unpaired electrons which capture these particles as they endeavor to pass therethrough.

The lack of electrical resistance of conductors at a critical superconductor state has long been recognized, and superconductors have been utilized to produce very high magnetic flux density electromagnets. FIG. 2 represents a cross section of a critical superconductor and the electron spins are indicated by the arrows 3.

A permanent magnet may be considered a superconductor as the electron flow therein does not cease, and is without resistance, and unpaired electric spinning particles exist which, in the practice of the invention, are utilized to produce motor force. FIG. 3 illustrates a horseshoe shaped permanent magnet at 4 and the magnetic flux therethrough is indicated by arrows 5, the magnetic flow being from the south pole to the north pole and through the magnetic material. The accumulated electron spins occurring about the diameter of the magnet 5 are represented at 6 in FIG. 4, and the spinning electron particles spin at right angles in the iron as the flux travels through the magnet material.

By utilizing the electron spinning theory of ferrous material electrons, it is possible with the proper ferromagnetic materials, geometry and magnetic concentration to utilize the spinning electrons to produce a motive force in a continuous direction, thereby resulting in a motor capable of doing work.

It is appreciated that the embodiments of motors utilizing the concepts of the invention may take many forms, and in the illustrated forms the basic relationships of components are illustrated in order to disclose the inventive concepts and principles.

The relationships of the plurality of magnets defining the stator 10 are best appreciated from FIGS. 5 through 8. The stator magnets 12 are preferably of a rectangular configuration, FIG. 8, and so magnetized that the poles exist at the large surfaces of the magnets, as will be appreciated from the N (North) and S (South) designations. The stator magnets include side edges 14 and 16 and end edges 18. The stator magnets are mounted upon a supporting plate 20, which is preferably of a metal material having a high permeability to magnetic fields and magnetic flux such as that available under the trademark Netic CoNetic sold by the Perfection Mica Company of Chicago, Illinois. Thus, the plate 20 will be disposed toward the south pole of the stator magnets 12, and preferably in direct engagement therewith, although a bonding material may be interposed between the magnets and the plate in order to accurately locate and fix the magnets on the plate, and position the stator magnets with respect to each other.

Preferably, the spacing between the stator magnets 12 slightly differs between adjacent stator magnets as such a variation in spacing varies the forces being imposed upon the armature magnet at its ends, at any given time, and thus results in a smoother movement of the armature magnet relative to the stator magnets. Thus, the stator magnets so positioned relative to each other define a track 22 having a longitudinal direction left to right as viewed in FIGS. 5 through 8.

In FIGS. 5 through 7 only a single armature magnet 24 is disclosed, while in FIG. 8 a pair of armature magnets are shown. For purposes of understanding the concepts of the invention the description herein will be limited to the use of single armature magnet as shown in FIGS. 5 through 7.

The armature magnet is of an elongated configuration wherein the length extends from left to right, FIG. 5, and may be of a rectangular transverse cross-sectional shape. For magnetic field concentrating and orientation purposes the magnet 24 is formed in an arcuate bowed configuration as defined by concave surfaces 26 and convex surfaces 28, and the poles are defined at the ends of the magnet as will be appreciated from FIG. 5. For further magnetic field concentrating purposes the ends of the armature magnet are shaped by beveled surfaces 30 to minimize the cross-sectional area at the magnet ends at 32, and the magnetic flux existing between the poles of the armature magnet are as indicated by the light dotted lines. In like manner the magnetic fields of the stator magnets 12 are indicated by the light dotted lines.

The armature magnet 24 is maintained in a spaced relationship above the stator track 22. This spacing may be accomplished by mounting the armature magnet upon a slide, guide or track located above the stator magnets, or the armature magnet could be mounted upon a wheeled vehicle carriage or slide supported upon a nonmagnetic surface or guideway disposed between the stator magnets and the armature magnet. To clarify the illustration, the means for supporting the armature magnet 24 is not illustrated and such means form no part of invention, and it is to be understood that the means supporting the armature magnet prevents the armature magnet from moving away from the stator magnets, or moving closer thereto, but permits free movement of the armature magnet to the left or right in a direction parallel to the track 22 defined by the stator magnets.

It will be noted that the length of the armature magnet 24 is slightly greater than the width of two of the stator magnets 12 and the spacing therebetween. The magnetic forces acting upon the armature magnet when in the position of FIG. 5 will be repulsion forces 34 due to the proximity of like polarity forces and attraction forces at 36 because of the opposite polarity of the south pole of the armature magnet, and the north pole field of the sector magnets. The relative strength of this force is represented by the thickness of the force line.

The resultant of the force vectors imposed upon the armature magnet as shown in FIG. 5 produce a primary force vector 38 toward the left, FIG. 5, displacing the armature magnet 24 toward the left. In FIG. 6 the magnetic forces acting upon the armature magnet are represented by the same reference numerals as in FIG. 5. While the forces 34 constitute repulsion forces tending to move the north pole of the armature magnet away from the stator magnets, the attraction forces imposed upon the south pole of the armature magnet and some of the repulsion forces, tend to move the armature magnet further to the left, and as the resultant force 38 continues to be toward the left the armature magnet continues to be forced to the left.

FIG. 7 represents further displacement of the armature magnet 24 to the left with respect to the position of FIG. 6, and the magnetic forces acting thereon are represented by the same reference numerals as in FIGS. 5 and 6, and the stator magnet will continue to move to the left, and such movement continues the length of the track 22 defined by the stator magnets 12.

Upon the armature magnet being reversed such that the north pole is positioned at the right as viewed in FIG. 5, and the south pole is positioned at the left, the direction of movement of the armature magnet relative to the stator magnets is toward the right, and the theory of movement is identical to that described above.

In FIG. 8 a plurality of armature magnets 40 and 42 are illustrated which are connected by links 44. The armature magnets are of a shape and configuration identical to that of the embodiment of FIG. 5, but the magnets are staggered with respect to each other in the direction of magnet movement, i.e., the direction of the track 22 defined by the stator magnets 12. By so staggering a plurality of armature magnets a smoother movement of the interconnected armature magnets is produced as compared when using a single armature magnet as there is variation in the forces acting upon each armature magnet as it moves above the track 22 due to the change in magnetic forces imposed thereon. The use of several armature magnets tends to "smooth out" the application of forces imposed upon linked armature magnets, resulting in a smoother movement of the armature magnet assembly. Of course, any number of armature magnets may be interconnected, limited only by the width of the stator magnet track 22.

In FIGS. 9 and 10 a rotary embodiment embracing the inventive concepts is illustrated. In this embodiment the principle of operation is identical to that described above, but the orientation of the stator and armature magnets is such that rotation of the armature magnets is produced about an axis, rather than a linear movement being achieved.

In FIGS. 9 and 10 a base is represented at 46 serving as a support for a stator member 48. The stator member 48 is made of a nonmagnetic material, such as synthetic plastic, aluminum, or the like. The stator includes a cylindrical surface 50 having an axis, and a threaded bore 52 is concentrically defined in the stator. The stator includes an annular groove 54 receiving an annular sleeve 56 of high magnetic field permeability material such as Netic Co-Netic and a plurality of stator magnets 58 are affixed upon the sleeve 56 in spaced circumferential relationship as will be apparent in FIG. 10. Preferably, the stator magnets 58 are formed with converging radial sides as to be of a wedge configuration having a curved inner surface engaging sleeve 56, and a convex outer pole surface 60.

The armature 62, in the illustrated embodiment, is of a dished configuration having a radial web portion, and an axially extending portion 64. The armature 62 is formed of a nonmagnetic material, and an annular belt receiving groove 66 is defined therein for receiving a belt for transmitting power from the armature to a generator, or other power consuming device. Three armature magnets 68 are mounted on the armature portion 64, and such magnets are of a configuration similar to the armature magnet configuration of FIGS. 5 through 7. The magnets 68 are staggered with respect to each other in a circumferential direction wherein the magnets are not disposed as 120.degree. circumferential relationships to each other. Rather, a slight angular staggering of the armature magnets is desirable to "smooth out" the magnetic forces being imposed upon the armature as a result of the magnetic forces being simultaneously imposed upon each of the armature magnets. The staggering of the armature magnets 68 in a circumferential direction produces the same effect as the staggering of the armature magnets 40 and 42 as shown in FIG. 8.

The armature 62 is mounted upon a threaded shaft 70 by antifriction bearings 72, and the shaft 70 is threaded into the stator threaded bore 52, and may be rotated by the knob 74. In this manner rotation of the knob 74, and shaft 70, axially displaces the armature 62 with respect to the stator magnets 58, and such axial displacement will very the magnitude of the magnetic forces imposed upon the armature magnets 68 by the stator magnets thereby controlling the speed of rotation of the armature.

As will be noted from FIGS. 4-7 and 9 and 10, an air gap exists between the armature magnet or magnets and the stator magnets and the dimension of this spacing, effects the magnitude of the forces imposed upon the armature magnet or magnets. If the distance between the armature magents, and the stator magnets is reduced the forces imposed upon the armature magnets by the stator magnets are increased, and the resultant force vector tending to displace the armature magnets in their path of movement increases. However, the decreasing of the spacing between the armature and stator magnets creates a "pulsation" in the movement of the armature magnets which is objectionable, but can be, to some extent, minimized by using a plurality of armature magnets. The increasing of the distance between the armature and stator magnets reduces the pulsation tendency of the armature magnet, but also reduces the magnitude of the magnetic forces imposed upon the armature magnets. Thus, the most effective spacing between the armature magnets. Thus, the most effective spacing between the armature and stator magnets is that spacing which produces the maximum force vector in the direction of armature magnet movement, with a minimum creation of objectionable pulsation.

In the disclosed embodiments the high permeability plate 20 and sleeve 56 are disclosed for concentrating the magnetic field of the stator magnets, and the armature magnets are bowed and have shaped ends for magnetic field concentration purposes. While such magnetic field concentration means result in higher forces imposed upon the armature magnets for given magnet intensities, it is not intended that the inventive concepts be limited to the use of such magnetic field concentrating means.

As will be appreciated from the above description of the invention, the movement of the armature magnet or magnets resultsfrom the described relationship of components. The length of the armature magnets as related to the width of the stator magnets and spacing therebetween, the dimension of the air gap and the configuration of the magnetic field, combined, produce the desired result and motion. The inventive concepts may be practiced even though these relationships may be varied within limits not yet defined and the invention is intended to encompass all dimensional relationships which achieve the desired goal of armature movement. By way of example, with respect to FIGS. 4-7, the following dimensions were used in an operating prototype:

The length of armature magnet 24 is 31/8", the stator magnets 12 are 1" wide, 1/4" thick and 4" long and grain oriented. The air gap between the poles of the armature magnet and the stator magnets is approximately 11/2" and the spacing between the stator magnets is approximately 1/2" inch.

In effect, the stator magnets define a magnetic field track of a single polarity transversely interrupted at spaced locations by the magnetic fields produced by the lines of force existing between the poles of the stator magnets and the unidirectional force exerted on the armature magnet is a result of the repulsion and attraction forces existing as the armature magnet traverses this magnetic field track.

It is to be understood that the inventive concept embraces an arrangement wherein the armature magnet component is stationary and the stator assembly is supported for movement and constitutes the moving component, and other variations of the inventive concept will be apparent to those skilled in the art without departing from the scope thereof. As used herein the term "track" is intended to include both linear and circular arrangements of the static magnets, and the "direction" or "length" of the track is that direction parallel or concentric to the intended direction of armature magnet movement.

Claims

What is claimed as new is as follows:

1. In combination with a movable armature, means for guiding movement of the armature along a predetermined path and a permanent armature magnet having magnetic poles of opposite polarity spaced from each other along said path to establish a magnetic field of limited extent movable with the armature and magnetic stator means for establishing a stationary magnetic flux zone along said path, the improvement comprising flux emitting surfaces of one polarity mounted on the stator means on opposite sides of said path for limiting said flux zone through which said path extends and means mounting the permanent armature magnet on the armature with the poles thereof orientated relative to said flux emitting surfaces on the stator means for unidirectionally propelling the armature along said path through the limited zone in response to magnetic interaction between the movable magnetic field and the limited flux zone, said magnetic stator means including a plurality of magnetic gate assemblies fixedly spaced from each other along said path and respectively establishing stationary magnetic fields, each of said gate assemblies including a plurality of interconnected bar magnets substantially bordering said limited flux zone exposing pole faces of opposite polarity in parallel spaced planes intersected by said path, and magnetic means connected to said interconnected bar magnets exposing one of the flux emitting surfaces of said one polarity perpendicular to said parallel planes for magnetic interaction of the stationary magnetic fields.

2. The combination of claim 1 wherein said armature magnet is curved between end faces at which said poles of opposite polarity are located, the end faces being orientated by the mounting means in converging relation to each other toward the guiding means.

3. In combination with a movable armature, means for guiding movement of the armature along a predetermined path and a permanent armature magnet having magnetic poles of opposite polarity spaced from each other along said path to establish a magnetic field of limited extent movable with the armature and magnetic stator means for establishing a stationary magnetic flux zone along said path, the improvement comprising flux emitting surfaces of one polarity mounted on the stator means on opposite sides of said path for limiting said flux zone through which said path extends and means mounting the permanent armature magnet on the armature with the poles faces thereof orientated relative to said flux emitting surfaces on the stator means for unidirectionally propelling the armature along said path through the limited zone in response to magnetic interaction between the movable magnetic field and the limited flux zone, said armature magnet being curved between end faces at which said poles of opposite polarity are located, the end faces being orientated by the mounting means in converging relation to each other toward the guiding means.

4. In combination with a movable armature, means for guiding movement of the armature along a predetermined path and a permanent armature magnet having

magnetic poles of opposite polarity spaced from each other along said path to establish a magnetic field of limited extent movable with the armature and magnetic stator means for establishing a stationary magnetic flux zone along said path, the improvement comprising flux emitting surfaces of one polarity mounted on the stator means on opposite sides of said path for limiting said flux zone through which said path extends and means mounting the permanent armature magnet on the armature with the poles thereof orientated relative to said flux emitting surfaces on the stator means for unidirectionally propelling the armature along said path through the limited zone in response to magnetic interaction between the movable magnetic field and the limited flux zone, said magnetic stator means including a pair of permanent magnet assemblies having continuous, confronting pole faces of said one polarity bordering said limited zone, each of said assemblies having means for varying magnetic field intensity in the flux zone along said path, and a second armature magnet connected to the first mentioned armature magnet in mirror image relation thereto.

5. The combination of claim 4 wherein said armature magnet is curved between end faces at which said poles of opposite polarity are located, the end faces being orientated by the mounting means in a plane parallel to said path.

6. In combination with a movable armature, means for guiding movement of the armature along a predetermined path and a permanent armature magnet mounted on the armature having magnetic poles of opposite polarity spaced from each other along said path, the improvement comprising a plurality of permanent magnet gate assemblies mounted in spaced relation to each other along said path establishing interacting stationary magnetic fields along said path, each of said assemblies including stator magnets interconnected in surrounding relation to said path and having pole faces of opposite polarity aligned with parallel planes intersected by said path and magnetic means fixed to the pole faces aligned with one of the parallel planes for interaction of the armature magnet with said stationary magnetic fields for unidirectional propulsion of the armature along said path, said magnetic means being an annular magnet having a radially inner pole surface of one polarity enclosing a magnetic flux zone through which said path extends.

Description

BACKGROUND OF THE INVENTION

This invention relates in general to the use of permanent magnets to generate unidirectional propelling forces.

The generation of unidirectional propelling forces by permanent magnets is already known and recognized in U.S. Pat. Nos. 4,151,431 and 4,215,330 to Johnson and Hartmen, respectively, by way of example. According to applicant's own prior Pat. No. 4,151,431, such forces are generated by magnetic interaction between a curved magnet bar of an armature guided for movement along a circular path and an arrangement of spaced stator magnets having pole faces of one polarity facing the armature on one side thereof parallel to the path of movement.

It is therefore an important object of the present invention to provide certain improved stator arrangements of permanent magnets interacting with a permanent magnet armature for unidirectional propulsion thereof in a novel manner believed to be more efficient.

SUMMARY OF THE INVENTION

In accordance with the present invention, the armature magnet is guided along a path through a magnetic flux zone limited on opposite sides of the path by an arrangement of magnetic pole surfaces of one polarity on stator magnets. According to one embodiment, the flux zone is formed by spaced gate assemblies of magnets having exposed pole faces of one polarity in a plane perpendicular to the armature path from which a magnetic field extends to the opposite pole faces and a ring magnet fixed to such opposite pole faces of the other polarity, with a radially inner pole surface of the same polarity producing a magnetic field perpendicular to the first mentioned field to their opposite radially outer pole surfaces.

According to another embodiment, the flux zone is formed between continuous confronting pole surfaces of one polarity on stator magnets arranged to produce a magnetic field of varying intensity along the armature path.

In yet another embodiment, at least two curved bar magnets are interconnected to form the armature with two pairs of pole faces spaced along the armature path.

These together with other objects and advantages which will become subsequently apparent reside in the details of construction and operation as more fully hereinafter described and claimed, reference being had to the accompanying drawings forming a part hereof, wherein like numerals refer to like parts throughout.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Referring now to the drawings in detail, FIG. 1 illustrates one embodiment of the invention in which a magnetic armature generally referred to by reference numeral 10 is unidirectionally propelled along a predetermined path established by a motion guiding track 12 fixed to a frame or support 14. The path is represented by a line 16 extending through pole faces 18 and 20 of opposite polarity at the longitudinal ends of a curved armature bar magnet 22. The armature 10 in the illustrated example includes a wheeled vehicle mount 24 to which the armature magnet 22 is fixedly secured with the pole faces 18 and 20 converging toward the guiding track 12. The pole faces 18 and 20 are furthermore orientated so that the magnetic field extending between pole faces 18 and 20 is movable therewith within a flux zone 26 limited in surrounding relation to the guided path at spaced locations by stator gate assemblies 28 formed by permanent magnets fixed to the frame support 14.

Each of the stator gate assemblies 28 as shown in FIGS. 1-3, includes four bar magnets 30 interconnected at corners by non-magnetic elements 32, such as triangular wooden blocks as more clearly seen in FIG. 3, to form a rectangular enclosure in surrounding relation to the track 12. Pole faces 34 and 36 between which a stationary magentic field extends are formed on the bar magnets substantially aligned with parallel spaced planes in perpendicular intersecting relation to the path line 16. The pole face

34 of one polarity (north) is effective through its magnetic field to magnetically interact with the magnetic field of the armature magnet 22 causing unidirectional propulsion of the armature 10 as actually observed during tests. Such magnetic interaction is obviously influenced by the pole face 36 of opposite polarity (south) abutting and fixed to an annular or circular ring magnet 38 magnets 30. The interconnected and 38 may be held in assembled relation by an outer skin or sheathing 40 as shown in FIG. 3.

The ring magnet 38 has a radially inner pole surface 42 of the same polarity (north) as that of the pole faces 34 to interact with the other pole faces 36 as aforementioned, to the exclusion of the radially outer pole surface 44. The obvious effect of said arrangement is to exert a net magnetic force on the armature magnet 22 causing the observed continuous, unidirectional propulsion thereof through the gate assemblies 28. Such assemblies 28 are spaced apart distance dependent on the magnetic field intensity or strength of the permanent magnets 30 and 38 which dictate the effective axial extent of the aforementioned magnetic fields associated with the assemblies 28 and the armature magnet 22.

FIGS. 4-7 illustrate another embodiment of the invention utilizing the same type of movable armature 10 guided along a predetermined path by a frame mounted track 12 extending through a flux zone 46 established by another type of permanent magnet stator arrangement, generally referred to by reference numeral 48. The stator 48 includes a pair of permanent magnet assemblies 50 extending in parallel spaced relation to each other on opposite sides of the armature path established by the track 12. Each assembly 50 is a mirror image of the other so as to expose continuous confronting pole surfaces formed by a magnetic layer material 52 such as Neodynium, mounted on interconnected ceramic bodies 54. The confronting pole surfaces of the magnetic layers 52 are of like polarity (north), opposite to the polarity of the pole surface of magnetic layer sections 56 and 58 made of Samarium Cobalt, for example, and carried on the ceramic bodies 54. The bodies 54 have transversely extending flange portions 60 at the abutting ends so as to mount the layer sections sections 58 laterally outwardly of layer sections 56 as more clearly seen in FIGS. 4 and 6 to thereby vary the magnetic field intensity along the guided armature path within the limited flux zone 46 in which the magnetic fields of the stator assembly 48 interact with the magnetic field of bar magnet 22.

The curved armature magnet 22 is orientated within the flux zone 46 between the confronting pole surfaces on 52 as depicted in FIG. 7, with the pole faces 18 and 20 converging toward the track 12 as previously described in connection with FIGS. 1-3. However, it was found that maximum propelling thrust is produced by optimum location of the path line 16 through the pole faces 18 and 20 a distance 62 closer to the upper edge of surface layer 52 than the lower edge on the frame support 14.

FIGS. 8 and 9 illustrate yet another embodiment of the invention involving the same type of permanent magnet stator arrangement 50 as described with respect to FIGS. 4-7. a modified form of armature 10' is featured in FIGS. 8 and 9, including two curved armature magnets 64 that are mirror images of each other with respect to an intermediate abutting portion 66. The magnets 64 are interconnected at the abutting portion 66 in alignment with a plane containing the path line 16 centrally between the confronting pole surfaces on 52. The end pole faces 68 and 70 for each magnet 64, are aligned with a plane in parallel spaced relation between the path line 16 and the pole surface on 52. With the number of pole faces thereby doubled for the armature, a higher and more efficient propelling thrust may be achieved.

The foregoing is considered as illustrative only of the principles of the invention. Further, since numerous modifications and changes will readily occur to those skilled in the art, it is not desired to limit the invention to the exact construction and operation shown and described, and accordingly, all suitable modifications and equivalents may be restorted to, falling within the scope of the invention.

US Patent # 5,402,021

Magnetic Propulsion System

Howard R. Johnson

(March 28, 1995)

Abstract --- A magnetic propulsion system including a plurality of specifically arranged permanent magnets and a magnetic vehicle propelled thereby along a path defined by the permanent magnets. The magnetic vehicle which is to be propelled includes a rigidly attached armature comprising several curved magnets. The propulsion system further includes two parallel walls of permanent magnets arranged so as to define the lateral sides of a vehicle path. Preferably, the walls are identical to one another except that the polarities of the magnets which define one wall are opposite from the polarities of the corresponding magnets in the opposite wall. A first wall, for example, includes a series of generally rectangular magnets, each magnet arranged with a North-to-South axis pointing longitudinally down the wall in the intended direction of vehicle travel. Each of the rectangular magnets is separated from the next successive rectangular magnet by a thinner magnet, which thinner magnet is arranged with its North-to-South axis pointing laterally toward the opposite wall and therefore perpendicular with respect to the North-to-South axis of the rectangular magnets. The opposite (or second) wall includes the same general arrangement of magnets, except that the North-to-South axis for each of the generally rectangular magnets is in a direction opposite from the direction of vehicle travel and the North-to-South axis of the thinner magnets points away from the first wall. In addition, the propulsion system includes several spin accelerators.

Description

FIELD OF THE INVENTION

The present invention relates to a magnetic propulsion system including a plurality of specifically arranged permanent magnets and a magnetic vehicle propelled thereby along a path defined by the permanent magnets.

BACKGROUND OF THE INVENTION

The generation of unidirectional propelling forces by permanent magnets is already known and recognized in U.S. Pat. Nos. 4,151,431 and 4,877,983 to Johnson, and U.S. Pat. No. 4,215,330 to Hartmen, by way of example. According to applicant's first patent (U.S. Pat. No. 4,151,431), such forces are generated by magnetic interaction between a curved magnet bar of an armature guided for movement along a circular path and an arrangement of spaced stator magnets having pole faces of one polarity facing the armature on one side thereof parallel to the path of movement.

According to applicant's second patent (U.S. Pat. No. 4,877,983), the armature magnet is mounted on a vehicle and guided along a path through a magnetic flux zone limited on opposite sides of the path by an arrangement of magnetic pole surfaces of one polarity on stator magnets. According to one embodiment of the second patent, the flux zone is formed by spaced gate assemblies of magnets having exposed pole faces of one polarity in a plane perpendicular to the armature path from which a magnetic field extends to the opposite pole faces and a ring magnet fixed to such opposite pole faces of the other polarity, with a radially inner pole surface of the same polarity producing a magnetic field perpendicular to the first mentioned field to their opposite radially outer pole surfaces. Several other embodiments are illustrated including variations in the armature structure and in the stator structure; however, all of the embodiments teach use of an annular stator assembly.

SUMMARY OF THE INVENTION

It is therefore an object of the present invention to provide an improved magnetic propulsion system having a plurality of permanent magnets and a magnetic vehicle propelled thereby along a path defined by the permanent magnets, wherein the permanent magnets need not encircle the path of the magnetic vehicle.

In order to achieve this and other objects, the present invention comprises two parallel walls of permanent magnets arranged so as to define the lateral sides of a vehicle path. The walls are identical to one another except that the polarities of the magnets which define one wall are opposite from the polarities of the corresponding magnets in the opposite wall.

A first wall, for example, includes a series of generally rectangular magnets, each magnet arranged with a North-to-South axis pointing longitudinally down the wall in the intended direction of vehicle travel. Each of the rectangular magnets is separated from the next successive rectangular magnet by a thinner magnet, which thinner magnet is arranged with its North-to-South axis pointing laterally toward the opposite wall and therefore perpendicular with respect to the North-to-South axis of the rectangular magnets.

The pole-to-pole length of each thinner magnet is preferably no more than half the width of the generally rectangular magnets. Accordingly, a gap on the inside surface of the wall is defined by the presence of each thinner magnet.

The opposite (or second) wall includes the same general arrangement of magnets, except that the North-to-South axis for each of the generally rectangular magnets is in a direction opposite from the direction of vehicle travel and the North-to-South axis of the thinner magnets points away from the first wall.

In addition, the propulsion system of the present invention includes several spin accelerators for crowding the magnetic fields at predetermined positions along the length of the walls. This crowding of the magnetic fields serves to intensify the fields and causes the vehicle's armature to be accelerated faster than would otherwise be the case without the spin accelerators.

The spin accelerators project laterally outward from each of the walls at predetermined positions along the longitudinal length of each wall. Each spin accelerator comprises a generally rectangular permanent magnet which is preferably identical to that of the first and second walls. Each spin accelerator further includes a shorter magnet having a smaller pole-to-pole length than that of the generally rectangular magnet and a wedge separating the generally rectangular magnet of the spin accelerator from the shorter magnet.

The orientation of the generally rectangular magnet in the spin accelerator is determined by which pole of the wall's thinner magnet is facing outwardly. The rectangular magnet's orientation is such that face-to-face contact is established between opposite poles of the generally rectangular magnet in the spin accelerator and the thinner magnet in the wall. Accordingly, the North-to-South axis of the generally rectangular magnet in the spin accelerator points in the same direction as the North-to-South axis of the thinner magnet in the wall. The shorter magnet in the spin accelerator is likewise arranged with its North-to-South axis pointing in the same general direction as that of the thinner magnet in the wall; but here, an acute angular tilt away from the North-to-South axis of the thinner magnet is established by the wedge. In particular, the angle of the wedge determines the acute angle which exists between the North-to-South axis of the shorter magnet in the spin accelerator and the North-to-South axis of the thinner magnet in the wall.

The magnetic vehicle which is to be propelled by the instant propulsion system includes a rigidly attached armature comprising several curved magnets. Each curved magnet is arranged on the vehicle such that its North-to-South axis is parallel with respect to that of the other curved magnets. In particular, the North-to-South axes of all the curved magnets point in the same direction as the North-to-South axes of the thinner magnets in each wall. The vehicle itself is preferably a wheeled vehicle mounted on a track; however, it is understood that other vehicle structures will suffice so long as the vehicle is maintained between the walls of the propulsion system.

In operation, the magnetic fields created by the two walls exert a propelling force on the armature of the vehicle in the desired direction of travel. Since the armature of the vehicle is rigidly attached to the vehicle, the vehicle itself begins to accelerate and is hence set in motion by the propulsion system.

Preferably, the curved magnets of the vehicle armature are "Alnico 8" magnets tipped with neodymium magnets. The magnets which constitute the walls and spin accelerators are preferably made of neodymium and ceramic material, except for the thinner magnets. The thinner magnets are preferably made of rubber or plastic, and each can comprise a plurality of magnetic rubber or plastic layers.

Although the present invention has been described with regard to generally rectangular magnets, it is understood that other permanent magnet shapes will suffice, including but not limited to generally cylindrical shapes.

BRIEF DESCRIPTION OF THE DRAWING

FIG. 1 is a schematic plan view of a magnetic propulsion system in accordance with a preferred embodiment of the present invention.

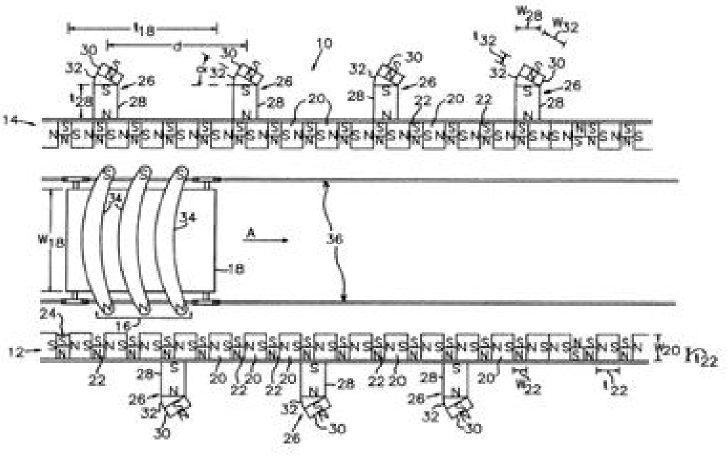

FIG. 1

DETAILED DESCRIPTION OF A PREFERRED EMBODIMENT

With reference to FIG. 1, a preferred embodiment of the inventive magnetic propulsion system and vehicle propelled thereby will now be described.

FIG. 1 schematically illustrates a propulsion system 10 comprising two parallel magnetic walls 12,14 which are stationary, and an armature 16 rigidly attached to a vehicle 18. The two parallel walls 12,14 are formed from several permanent magnets arranged so as to define the lateral sides of a vehicle path. The desired direction of vehicle travel is indicated by an arrow A in FIG. 1. The two walls 12,14 are identical to one another except that the polarities of the magnets which define one wall 12 are opposite from the polarities of the corresponding magnets in the opposite wall 14. A first wall 12, for example, includes a series of generally rectangular magnets 20, each magnet arranged with a North-to-South axis pointing longitudinally down the wall in the intended direction of vehicle travel (indicated by arrow A). Each of the magnets 20 preferably comprises a ceramic magnet with a neodymium north pole. In addition, each of the generally rectangular magnets 20 is separated from the next successive rectangular magnet 20 by a thinner magnet 22. The thinner magnets 22 are arranged with their North-to-South axes pointing laterally toward the opposite wall 14 and therefore perpendicular with respect to the North-to-South axis of the rectangular magnets 20. Each thinner magnet 22 is preferably made from rubber or plastic permanently magnetic material. Also, the pole-to-pole length of each thinner magnet 22 is preferably no more than half the width of the generally rectangular magnets 20.

Consequently, a gap 24 on the inside surface of the wall 12 is defined by the presence of each thinner magnet 22.

The opposite (or second) wall 14 includes the same general arrangement of magnets 20,22, except that the North-to-South axis for each of the generally rectangular magnets 20 points in a direction opposite from the direction of vehicle travel, while the North-to-South axes of the thinner magnets 22 point away from the first wall 12.

By arranging the thinner magnets 22 between the generally rectangular magnets 20 in the foregoing manner, there is a pole shading effect on the magnets 20 of the walls 12,14.

In addition, the propulsion system 10 of the preferred embodiment includes several spin accelerators 26 for crowding the magnetic fields at predetermined positions along the length of the walls 12,14. This crowding of the magnetic fields serves to intensify the fields and causes the vehicle's armature to be accelerated faster than would otherwise be the case without the spin accelerators.

The spin accelerators 26 project laterally outward from each of the walls 12,14 at predetermined positions along the longitudinal length of each wall 12,14. According to the preferred embodiment, the spin accelerators 26 are positioned along the walls 12,14 at every other thinner magnet 22 (as is shown in the middle of FIG. 1). Each spin accelerator 26 comprises a generally rectangular permanent magnet 28 which is preferably identical or very similar to that of the first and second walls 12,14. Each spin accelerator 26 further includes a shorter magnet 30 having a smaller pole-to-pole length than that of the generally rectangular magnet 28 and a wedge 32 separating the generally rectangular magnet 28 of the spin accelerator 26 from the shorter magnet 30. The orientation of the generally rectangular magnet 28 in the spin accelerator 26 is determined by which pole of the wall's thinner magnet 22 is facing outwardly. The rectangular magnet's orientation is such that face-to-face contact is established between opposite poles of the generally rectangular magnet 28 in the spin accelerator 26 and the thinner magnet 22 in the wall 12,14. Accordingly, the North-to-South axis of the generally rectangular magnet 28 in the spin accelerator 26 points in the same direction as the North-to-South axis of the thinner magnet 22 in the wall 12,14. The shorter magnet 30 in the spin accelerator 26 is likewise arranged with its North-to-South axis pointing in the same general direction as that of the thinner magnet 22 in the wall 12,14; but here, an acute angular tilt away from the North-to-South axis of the thinner magnet 22 is established by the wedge 32. In particular, the angle .alpha. of the wedge determines the acute angle which exists between the North-to-South axis of the shorter magnet 30 and the North-to-South axis of the thinner magnet 22 in the wall 12,14. The shorter magnet 30 preferably consists of neodymium.

The magnetic vehicle 18 which is to be propelled by the instant propulsion system 10 includes a rigidly attached armature 16 comprising several curved magnets 34. Each curved magnet 34 is arranged on the vehicle 18 such that its North-to-South axis is parallel with respect to that of the other curved magnets 34. In particular, the North-to-South axes of all the curved magnets 34 point in the same direction as the North-to-South axes of the thinner magnets 22 in each wall 12,14. The vehicle 18 itself, according to the preferred embodiment, is a wheeled vehicle mounted on a track 36. It is understood, however, that other vehicle structures will suffice so long as the vehicle is maintained between the walls 12,14 of the propulsion system 10.

In operation, when the vehicle 18 is positioned as is shown in FIG. 1, the magnetic fields created by the two walls 12,14 exert a propelling force on the armature 16 of the vehicle 18 in the desired direction of travel (arrow A). Since the armature 16 is rigidly attached to the vehicle 18, the vehicle 18 itself begins to accelerate and hence is set in motion by the propulsion system 10.

Furthermore, since the spin accelerators 26 serve to crowd and thereby intensify the magnetic fields at predetermined positions along the walls 12,14, the acceleration of the vehicle is enhanced as the vehicle passes these predetermined positions.

The spin accelerators 26 can be reversed in order to lessen their effectiveness at crowding the magnetic fields. Reversing of the spin accelerators 26 can be accomplished by rotating the spin accelerators 26 so that the shorter magnets 30 tilt away from the intended direction of vehicle travel, rather than in the direction of travel as is the case for the illustrated embodiment.

Preferably, the curved magnets 34 of the vehicle armature 16 are "Alnico 8" magnets tipped with neodymium magnets, while the wedges 32 comprise wood or similar material and an angle .alpha. of 45 to 90 degrees.

The width w.sub.20, height, and pole-to-pole length 1.sub.20 of the generally rectangular magnets 20 in each wall 12,13 are 0.75 inches to 1.25 inches, 3.75 to 4.25 inches, and 1.25 inches to 1.75 inches, respectively. The width w.sub.22, height, and pole-to-pole length 1.sub.22 of the thinner magnets 22 in the walls 12,14 are 1 inch to 1.5 inches, 3.75 inches to 4.25 inches, and no more than one half the width w.sub.20 of the generally rectangular magnets, respectively. In the spin accelerators 26, the width w.sub.28, height, and pole-to-pole length 1.sub.28 of the generally rectangular magnets 28 are 1.125 to 1.625 inches, 3.75 to 4.25 inches, and 0.875 inches to 1.375 inches, respectively, while the width w.sub.32, height, and pole-to-pole length 1.sub.32 of the shorter magnets 30 are 0.75 inch to 1.25 inches, 3.75 inches to 4.25 inches, and 0.125 inch to 0.375 inch, respectively.

Preferably, the distance separating the walls 12,14, is such that each wall 12,14 is 0.5 inch to 1.25 inches away from the tips of the armature magnets 34, both walls 12,14 being equidistant from the tips of the armature 16. Also, the curved magnets 34 of the armature 16 are preferably 0.375 inch to 0.625 inch apart from one another.

Testing of the foregoing prototype propulsion system resulted in the vehicle moving 2 feet in one second.

Although the present invention has been described with reference to a preferred embodiment, it is understood that various modifications to this embodiment will become subsequently apparent to those having ordinary skill in the art. In this regard, the scope of the invention is limited only by the claims appended hereto, and not by the illustrated embodiment.

Subject: Truth about Howard Johnson and his motor

Sterling,

Just a quick note to let you know I spoke to Tom Bearden today and, regarding the statement on your webpage by your "anonymous source" who said "Howard Johnson never was able to get the rotary version to work. He was only able to get the linear version working, and there were some questions about its viability.", Tom said such a person doesn't know what they are talking about. I'd say Tom is in the best position to know, since he and Howard have been friends for decades and Howard has personally brought a functional, rotary PMM to Tom's house, and they've played with it for hours. Next to Howard himself, I'd consider Tom to be the best resource on the subject of HJ's PMM.

He also said that Howard is still working on getting another functioning unit constructed (he's had numerous setbacks over the years after his working unit was vandalized by thieves that broke into Howard's shop and stole only the magnets off that model, leaving many $K worth of other material nearby untouched). Howard is still plugging away every day, at over 70 years old, but his wife's health problems are keeping him busy. However, he has gotten hooked up with a respectable, honest businessman who is financing him and Howard also now has some younger help to do the grunt work that is becoming tougher for him. All in all, Tom hopes to see some real progress being made for Howard in the next year or so.

Tom mentioned that there are a few critical things that anyone who wants to successfully build a working HJ PMM needs to know, some of which are probably obvious to the more experienced builders:

1) The most critical element is the precise machining of the magnets. Joe Q. Public, with his diamond saw, cutting his own magnets by hand has little chance of succeeding in shaping the magnets to the aerospace-critical specs that are the minimum necessary, much less duplicating that feat several times for each necessary part.

2) Alignment of the parts is highly important too. One slight misalignment and the motor will not run continuously.

3) All magnets aren't the same. This application requires expensive, extremely high quality magnets. Howard, in order to get them cheaper, was buying them in $50K lots from China, where high quality and a lower price can be had.

I also spoke with a gentleman named Gary Hanson who had been in touch with Howard years ago when Gary was trying to build Howard's motor. Howard told him, as I think most researchers on this know now, that the motor *can* be build directly from the patent but that there needs to be 5 or 6 armtures and not just the one that is shown as an illustration in the patent. Just want to make sure any newbies understand this.

I hope some of this has helped clear up any misunderstandings for those of us interested in building a functional HJ PMM. My opinion is that, if you want to do it right, go to the horse's mouth (Howard) or else as close as you can possibly get (Tom). Hopefully, doing so will enable us to make this motor a reality.

Regards, Karl

Tom Bearden: ***Chasing the Wild Dragon*** **[**Excerpts from www.cheniere.org]

Howard Johnson is also a respected colleague, whom I very much admire. (See Figure 23). Howard has continued to work quietly and patiently upon his patented permanent magnet motor, [note 31] including patenting various magnetic gates, etc. that are necessary to make such a motor work in a rotary configuration. [note 32] Howard employs a two-particle theory of magnetism; i.e., each magnetic flux line is envisioned as having a particle traveling from the north pole to the south pole, and also a particle traveling from the south pole to the north pole. The particles are spinning; the forward-time particle spins in one direction, and the antiparticle spins in the other direction. Howard then slightly separates the two particle flows. [note 33] In other words, Johnson splits the flux lines themselves, into two different pieces. When so separated, the component lines are now curls, so their paths curve. The paths of the two "curl particles" are different; one curls in one direction and the other curls in the opposite direction. Further, a predominance of one form of curl particle gives a "time-forward" aspect, while a predominance of the other form of curl particle gives a "time-reversed" aspect. Johnson is thus able to employ a deeper kind of magnetism than the textbooks presently contain. He demonstrates that a "spin-altered" magnetic assembly exhibiting (to a compass or other such detector) a north polarity can attract another unaltered magnetic assembly exhibiting a north polarity. In short, he can make a north pole attract a north pole. We will give you further insight into Johnson's two-particle theory in a future article. [note 34] We will also explain how and why the physicists missed that antiparticle in the magnetic field's flux lines, and thereby failed to advance the theory of magnetism to a deeper level. Make no mistake, one day when the new theory is done, Johnson may well be awarded a Nobel Prize for his epochal discovery of a deeper structure of magnetism.

Footnotes:

[32] I personally saw and closely examined one demonstration rotary Johnson permanent magnet motor some years ago, and toyed with it for about one hour. It would definitely self- rotate as long as you wished to permit it to turn. It was not a powerful device at all, but just a small laboratory "proof of principle" prototype. It had cost Johnson an enormous amount of time, labor, and optimization to get the critical adjustment required of his two magnet assemblies. But the device had no power source other than the permanent magnet assemblies themselves. Johnson's nonlinear rotor and stator magnets interacted with each other in a manner to break local symmetry. So his machine was an open system and therefore a permissible overunity device; it was not a perpetuum mobile.

[33] As I have pointed out repeatedly in the past, photons also carry time, not just energy. We have previously shown the process and the photon interaction mechanism that creates the flow of time itself; we will discuss this mechanism in the future. So when Johnson separates the particles and antiparticles, not only does he partially separate them according to spin, but he also alters the local character of time flow during which the resulting magnetic field forces must appear. In other words, he accomplishes a partial separation of time-forward and time- reversed polar interactions. A south pole is just a time- reversed magnetic north pole, in the first place! So a north pole of a bar magnet that is slightly time reversed on one side will

partially act on that side just like a south pole. On the other side it will continue to act like a normal north pole. By partially time-reversing (phase conjugating) one side of the north magnetic pole piece, Johnson makes that side look and act like a south pole. that way Howard is able to create two north poles, one on a stator and the other on a rotor, and time-reverse part of one face of the stator's north magnetic pole-piece. Therefore when the proper sides of the stator and rotor north poles are facing, they attract each other, contrary to the conventional textbook. The two poles then repel each other normally as soon as the north rotor poles passes the north stator pole. Hence Johnson can make a surrounding north pole stator assembly "draw in" an approaching north pole rotor assembly, and then kick it on out the other side, because he has broken the local magnetic symmetry. In short, Johnson's magnetic gate can provide a legitimate component of unidirectional magnetic thrust, which means that he can indeed make a rotary permanent motor. Simply put, this "partially separating the spin particles," and thereby partially phase conjugating one face of a magnet, is what Johnson calls a "gate," and this is the patented secret by which his magnet assemblies can be made self-powering. The entire process is still very meticulous, and assembly and adjustments are extremely critical. With Johnson's blessings we hope to shed more light on this subject in coming articles.

[34] For a basic article on rotary permanent magnet motors, see T.E. Bearden, "On Rotary Permanent Magnet Motors and 'Free' Energy," *Raum & Zeit*, 1(3): 43-53 (Aug.-Sep. 1989).

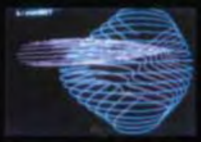
The secret world of Magnets

By the father of spintronics,
Howard Johnson



DEDICATION

This book is lovingly dedicated in memory of Dr. Gerhard H. Beyer, Distinguished University Professor at Virginia Polytechnic Institute and State University, Blacksburg, Virginia. He was former Head of Department of Chemical Engineering; Fellow in the Chemical Engineering Society and Active in the Nuclear Engineering Society and the Society of Professional Engineers. He enjoyed teaching and advanced research, including the discoveries and development of this book.

Howard Johnson first became interested in magnetics while doing some graduate work at Vanderbilt University. Several patents later he was joined by Jerry Beyer, a senior scientist in Chemical Engineering at V.P.I., and Steve Davis, an electrical engineer and leading computer man. Together they broke some of the magnetic code which they present here just as they found it.

"There is a God in heaven that revealeth secrets, and maketh known to the king Nebuchadnezzar what shall be in the latter days."

Daniel 2:1-28

"Hast thou entered into the treasures of the snow?". . .

"Which I have reserved against the time of trouble, against the day of battle and war? "

Job 38:22,23

WHO DISCOVERED MAGNETS?

BY DR. GERHARD H. BEYER

We'll never really know — it happened such a long time ago . ..

Maybe someone picked up a piece of "magnesian" rock on an Aegean coast and noticed the piece of lodestone was peculiar. It attracted a piece of iron, and could change the properties of the iron when the iron was rubbed with the rock.

Thales — who lived in Greece about 600 B.C. — studied attractive forces associated with magnets, and a resin called "amber." That started the long history of magnetism and electricity that is still being added to today.

It may have been that some Chinese used magnetic stones which pointed northward to find their way through the Gobi Desert many centuries ago.

The use of a magnetized needle floated on a cork, that has developed into the compass we know today, was a great boon to explorers and markedly changed our world.

More recently, the discoveries of new materials — such as ferrites and rare earth magnets — are likely to change our world again.

Have you ever wondered about:

How magnets work?
Why some elements are magnetic and others aren't?
How a magnet manages to change things without touching them?

This book may suggest at least partial answers to some of these questions. But most likely there will still be more questions than answers, for there are many things still to be discovered about magnets.

More work needs to be done. Maybe YOU will do it if you get inerested in magnets. That's one of the reasons for this book.

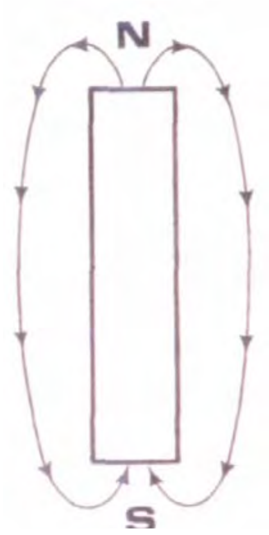
Way back in 1734, a Swedish scientist named Swedenborg showed the difference between magnetized iron and unmagnetized iron. And since then, we've discovered a lot of new materials and new techniques. Today there are better sensors for making measurements, and there are computers to help in recording, analyzing, and displaying them.

Another reason for this book is to tell you about these new materials and techniques and to show you some magnetic patterns no one else has ever seen.

The Direction of Magnetic Fields

For generations, physics students and others have been taught about magnets with iron filings.

It has been the popular belief of almost anyone with a common knowledge of magnetics that the pattern made by the filings represents the form and the movement of the magnetic fields. The following is an illustration of the popular view, using a simple bar magnet:



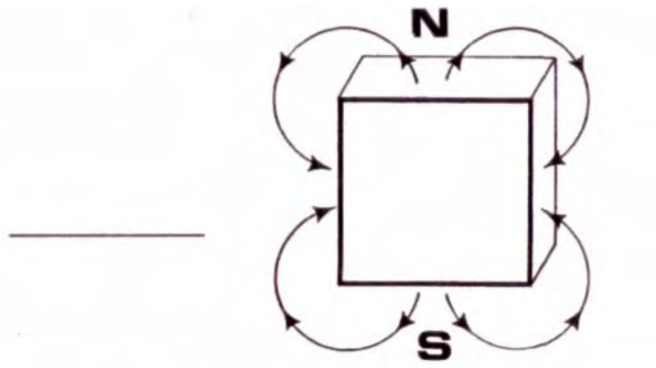
The over simplification of magnetic field, showing its movement from the north pole of the magnet to the south pole.

Today, however, it is quite evident that filings do not show magnetic fields as they are, but that they show what little pieces of magnets do in magnetic fields. The two are about as much alike as a Venetian blind and a blind Venetian.

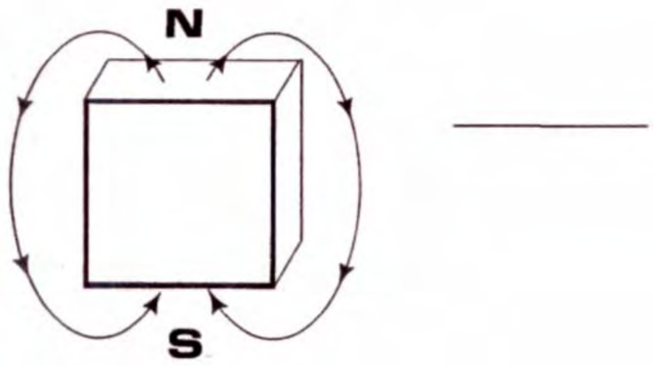
The pieces of iron become little magnets that attract to each other, and are not free moving particles in the magnetic field, and cannot act as a dye to show where the fields are and what they look like.

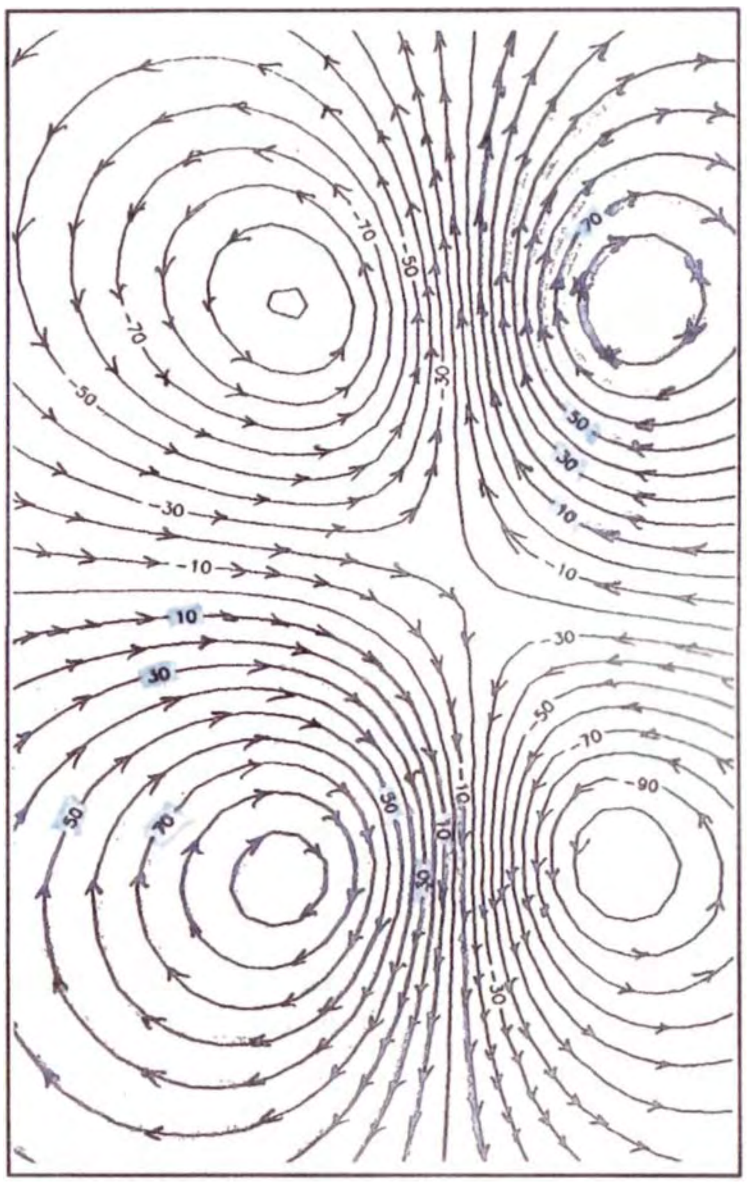
These lines of force, that is, the magnetic fields, are much more complex than most minds would ever conceive. The concept that is about to be introduced here has been verified through much research, and will be demonstrated by experiments throughout the book.

This is what the direction of the lines of force really looks like, demonstrated with a cubical magnet having the top face for the north pole and the bottom face for the south pole:



As opposed to this:





This actual graphic mapping of a magnet shows its lines of force by measuring the intensity of the magnetic field every 1/16" at each point on a grid, covering the entire magnet, as well as some of the field in the area around the magnet. (Sec page # 29 for description of method.) This measurement of the strength of the magnetic field is rated in gauss.

Upon careful examination of the illustration on page 3, you will notice that the lines of force leaving either pole are going in opposite directions.

For this to be possible, you must have two completely different lines of force which distinguish the north pole from the south pole, the difference being the direction of the lines of force. This brings us to the theory in which this work is based:

The lines of force of which a magnetic field consists are the track of a particle.

But, reason tells us, that if the illustration be true, and the lines of force are the track of a particle, then since there arc two lines of force, then there must be two different particles.

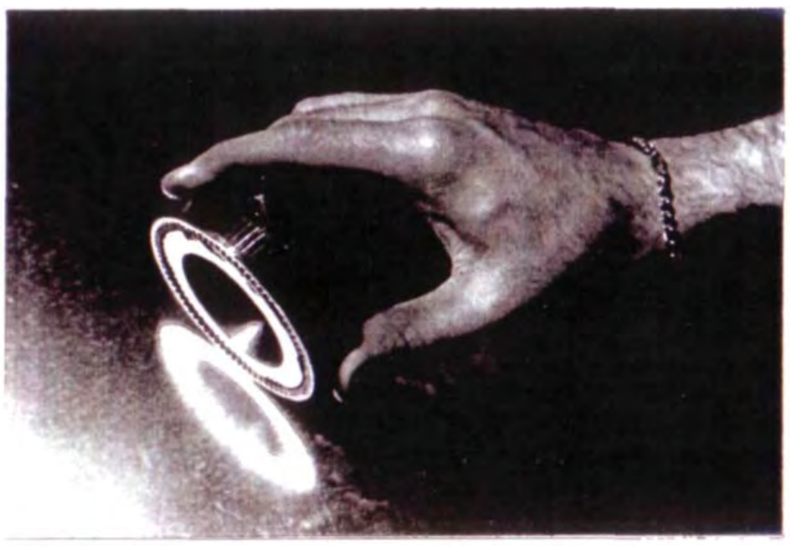
The knowledge of the existence of two particles came about by the design of a generator. As a result of DC. current being sent in one direction through a magnetizer around the rotor to be magnetized, alternating north/south poles are laid down. In illustrations:

The magnetizer, designed by George Eyerly, is assembled.

MAGNETIZING
A 92 POLE PERMANENT
MAGNET GENERATOR ROTOR

92 alternating north/south poles appear on the rotor. It is now ready to generate.

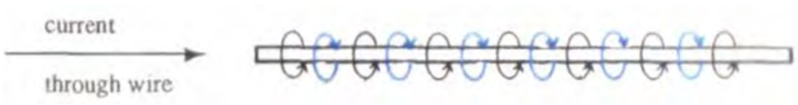
The preceding process uses the two particle principle, laying down lines going in opposite directions around a current carrying wire.



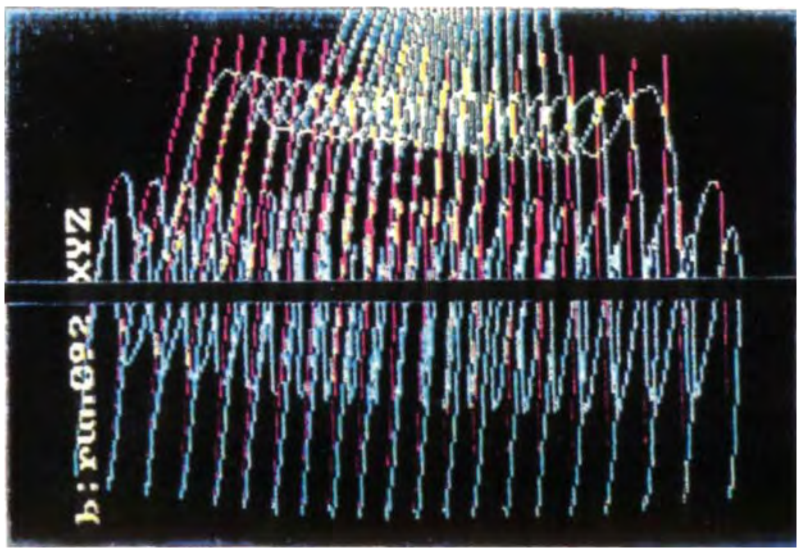
The rotor is put inside and a single wrap of conductor is placed around it.

A magnetizing current is released through the copper and . . .

This is made possible in keeping with the principle that, around the wire conducting current, these two opposing particles orbit in opposite directions. Illustration:



current
through wire

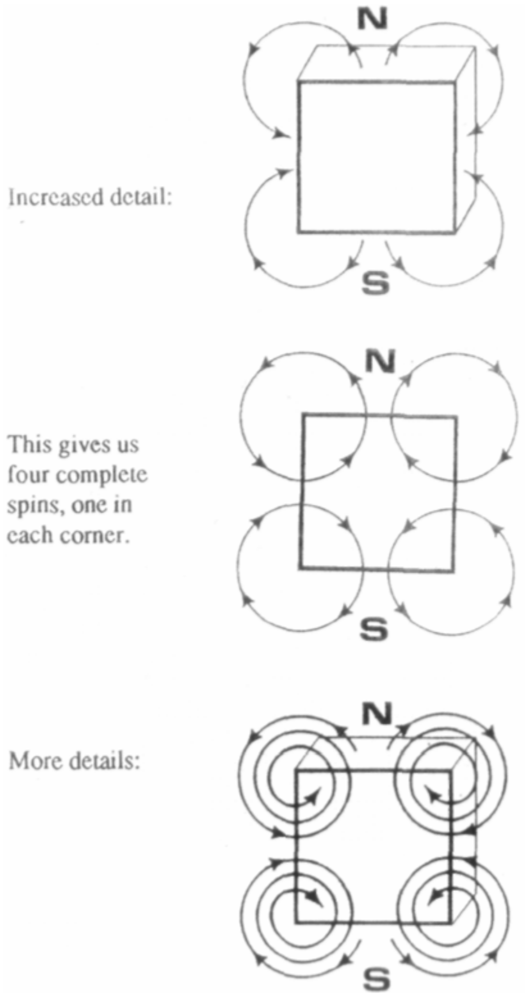


Computer color illustration.

In the permanent magnet, we have the same two spins in opposite directions. We do not know what makes them behave that way, but we do believe the record of our excellent monitoring and recording equipment.

Lines of Force are Spins forming Vortices

One of the most most amazingly illustrative and thoroughly innovative concepts in the area of magnetic field structure has been the discovery of vortices caused by the path of the particles which make up the lines of force. Notice the previously used illustration:



N
Increased detail:
S

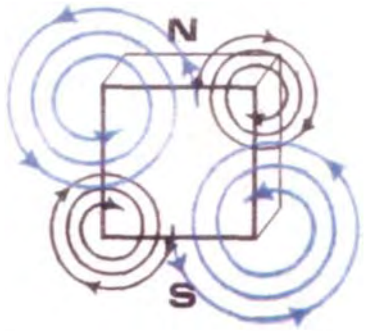
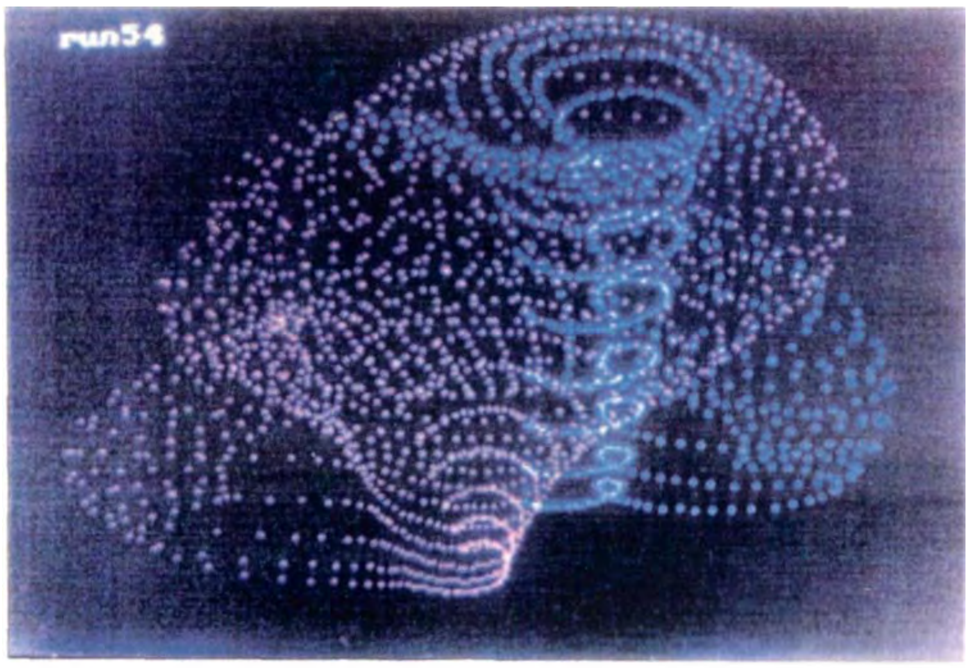
More details:
S

THE DOUBLE VORTEX WITH THE SPINS ALONGSIDE





Here is the picture which recorded the discovery of the Double-Vortex

Noticing the last illustration, it is evident that the "whirlwind" or "tornado" effect is present and that there are two vortices present at each "pole".

An interesting and important piece of information, though, is that these vortices are not all the same, as is shown in previous illustration for clarity. Notice the distribution of the spins:

The Double-Vortex is highly significant in many ways, but the point to be reckoned with here is that both particles exist at both poles. Therefore, there is an element of both the "north" and the "south" in each pole. The north element (vortex) is dominant, and has proven to be the stronger vortex with higher gauss ratings.

Since the stronger north element (vortex) exists in both poles, you are sure to ask what the deciding factor is that distinguishes the north pole from the south pole. The same illustration just used shows that the north pole is the one with the weakest south element (vortex). This means the other pole must be south.

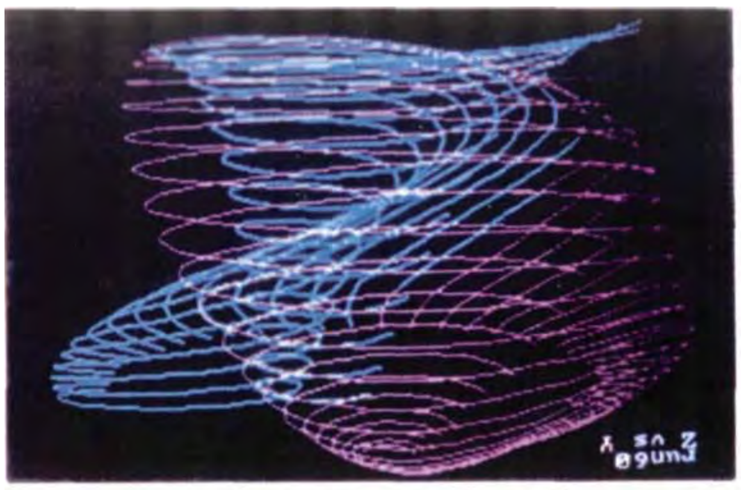
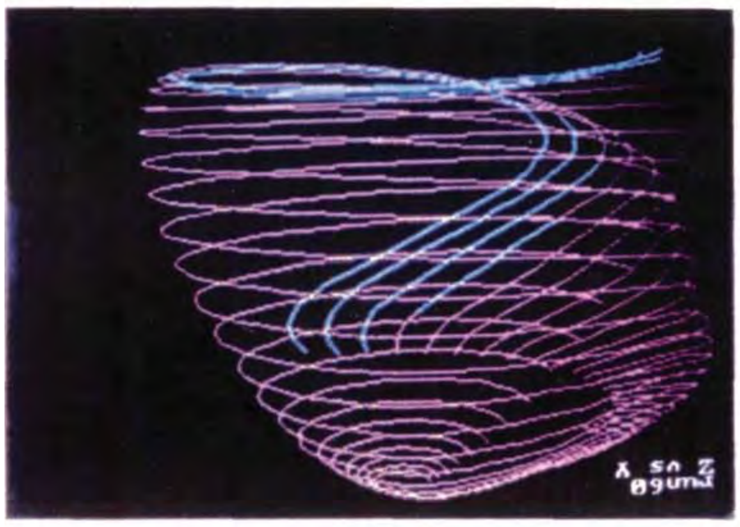
Shown here are the double vortex sets at each pole of a magnet.

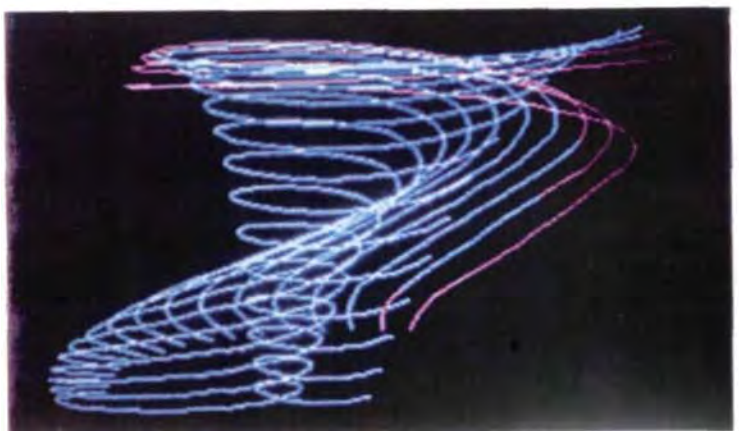
This is a topographical map of the fields at the end of a square ceramic bar magnet magnitized through its thickness.



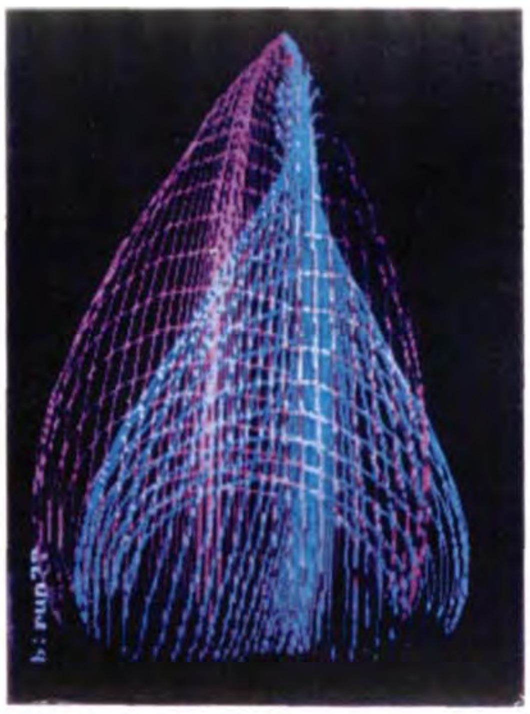
The
Double
Vortex:



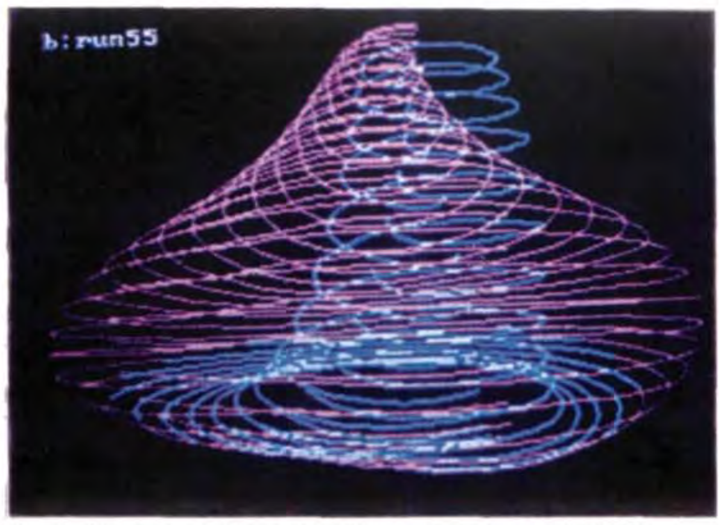
This vortex
is the
north element.



This vortex
is the
south element.



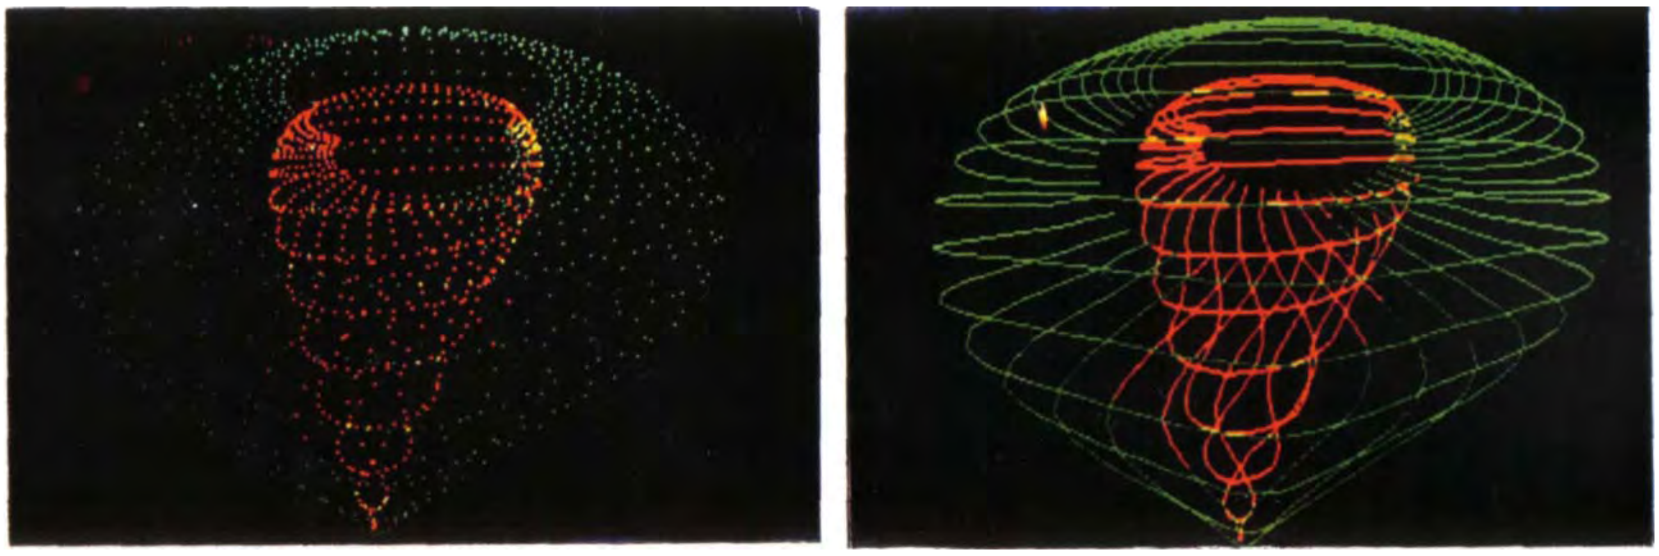
The Double Vortex of a different magnet
mapped at a slightly different angle.



Slightly different materials result in different formations of the fields.

When dealing with Double Vortices, different arrangements of magnets can be used to manipulate the form in which a Double Vortex shows up.

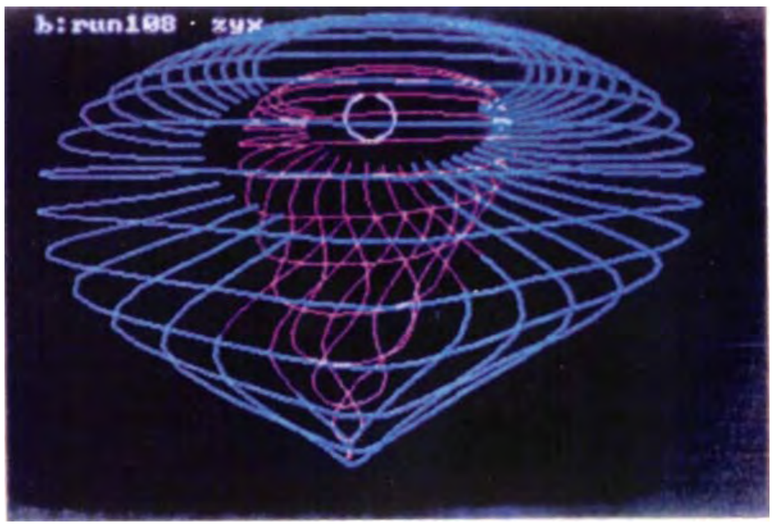
In a different experiment, in which layers of different kinds of magnets are used, the manipulation of the strengths of the different layers produced the formation of a vortex within a vortex. Notice illustrations and descriptions:



The 3-D mapping showing the tracks of the
particles in a particular "vortex in a vortex"

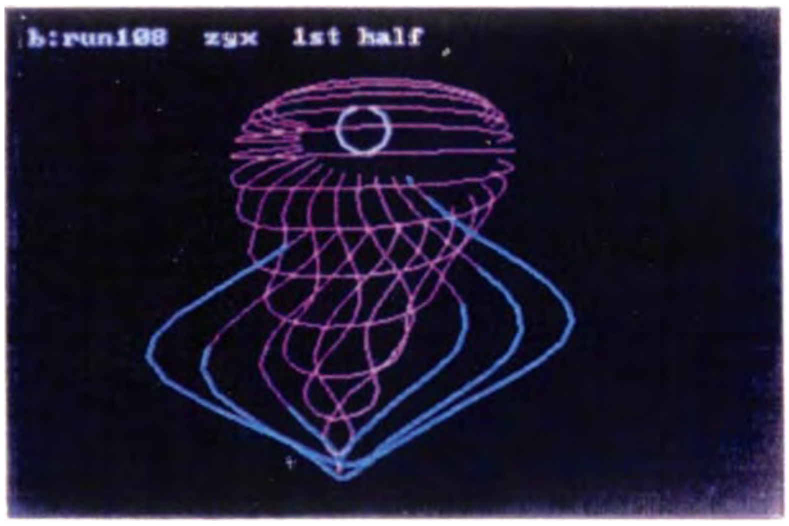
The following three pictures show the vortex in a vortex (a), the "south" vortex (b), and the "north" vortex (c).

(a)



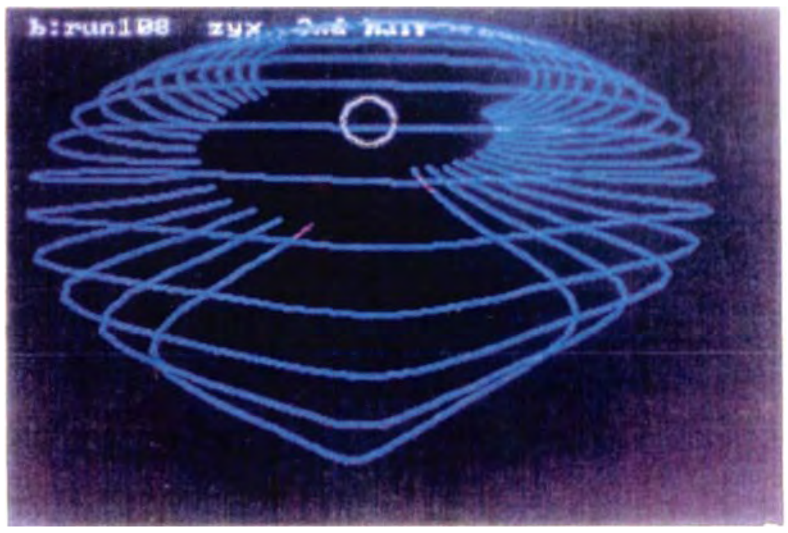
b:run108 · zyx

(b)

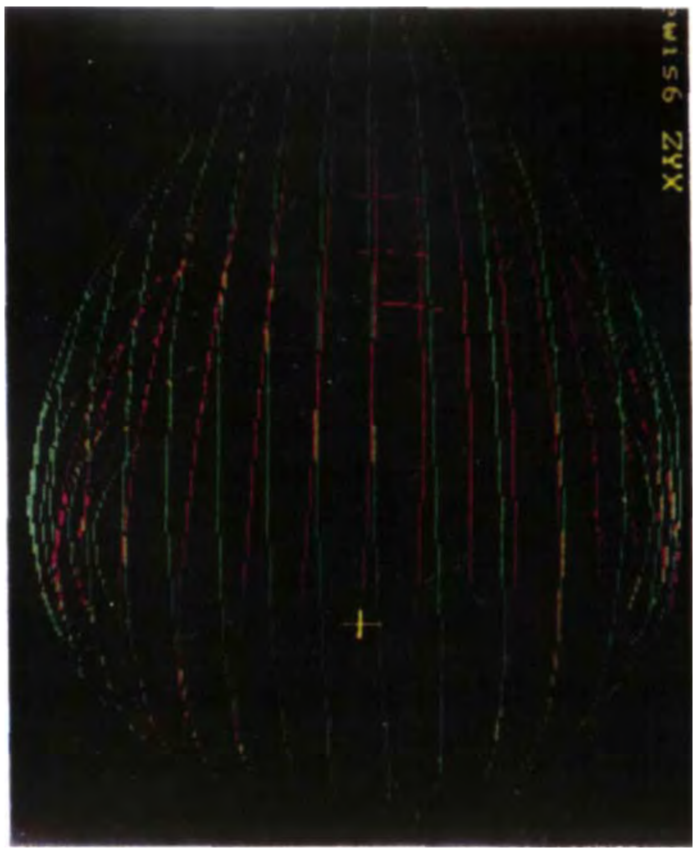


b:run108 zyx 1st half

(c)

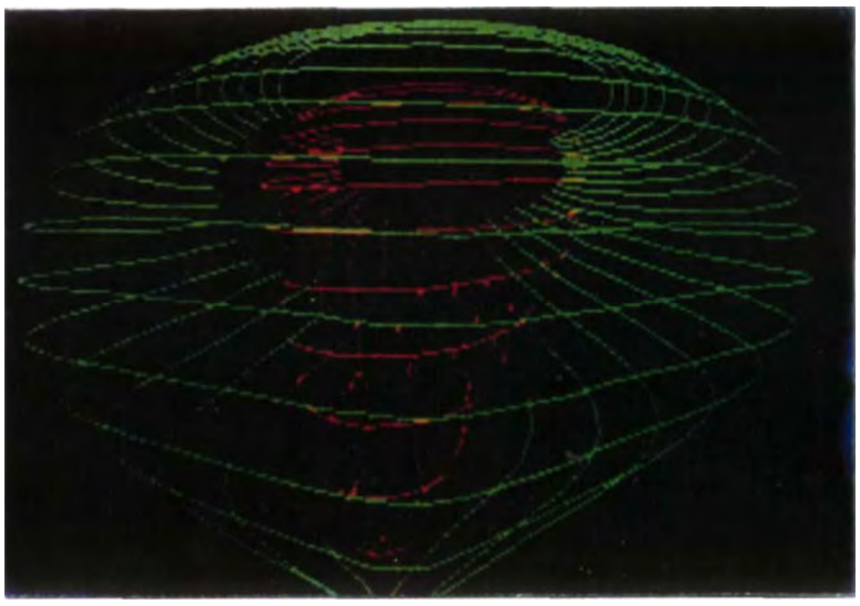


b:run108 zyx 2nd half



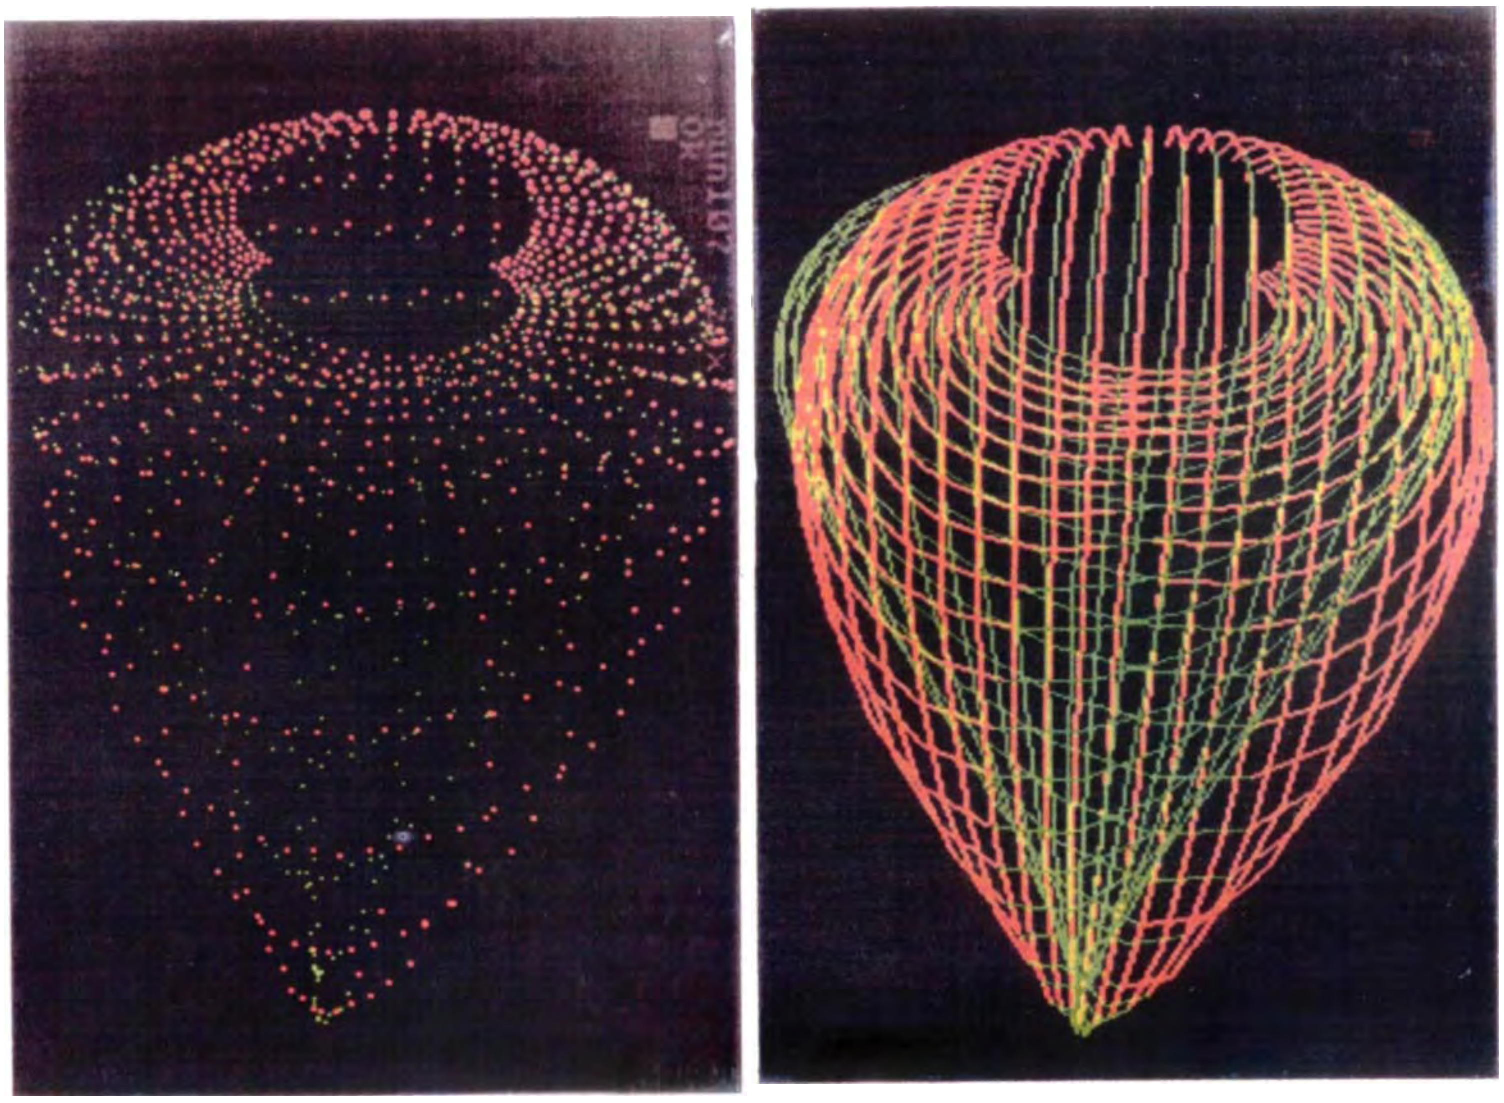
The vortex within another vortex is formed by the combination of three different magnets. The fields shown exist immediately above them when they are layered like a sandwich and standing on edge. This magnetic sandwich is composed of a ceramic magnet, neodymium magnets, and magnetic rubber or vinyl (similar to that on the door of your refrigerator).

The computer is also used to register the percentages of the two particles that make up the two vortices. (See "Mapping of Magnetic Fields" on page 29.) These percentages are important in determining the momentum of the magnetic field. These two populations are distinguishable in the recording process because the different particles are going in opposite directions.



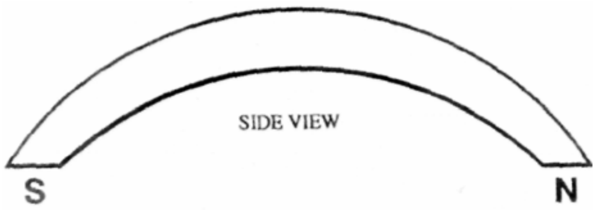
Notice the 3-D effect that the mapping produces.

The Double Vortex in a different magnet has a different form, as is shown here.

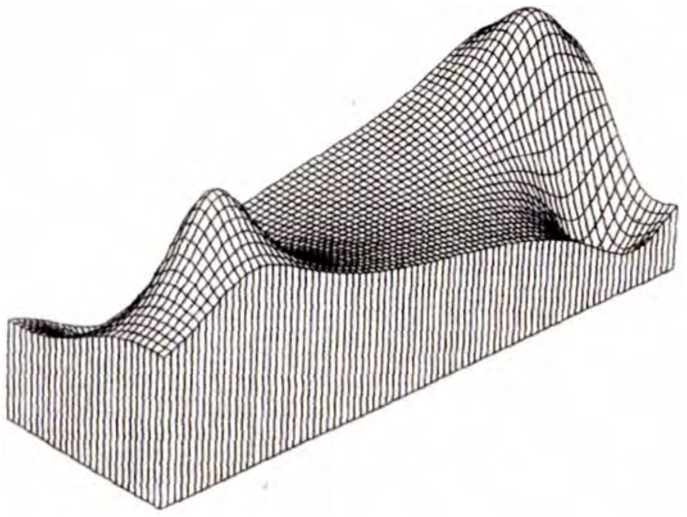


The following is a theory that may help to explain the various conditions of the Double Vortices:

Since the Double Vortices can be arranged so that they are in different relationships to each other (i.e., alongside or within each other) their relationship to each other determines, or may determine the momentum of the field.



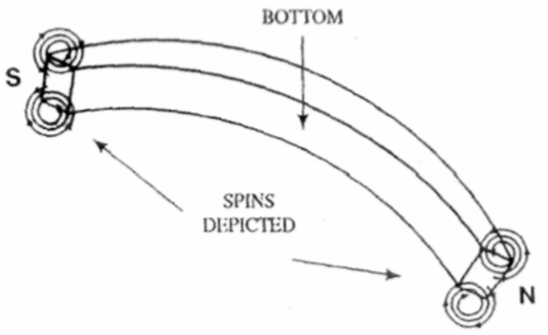
Here is a graphic computer printout of the plotting picturing the above.

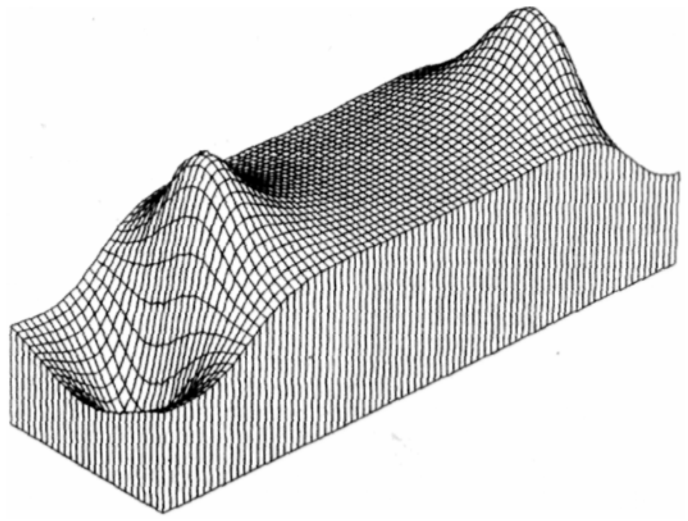


The different axes show the Double Vortices at either pole.

Case in point: Maybe the vortex in a vortex demonstrates the apex of unity and concentration of the field, giving a single pole the most direct thrust possible.

A magnet that clearly depicts the two vortices at each pole is the "banana" shaped curved magnet. The magnet:





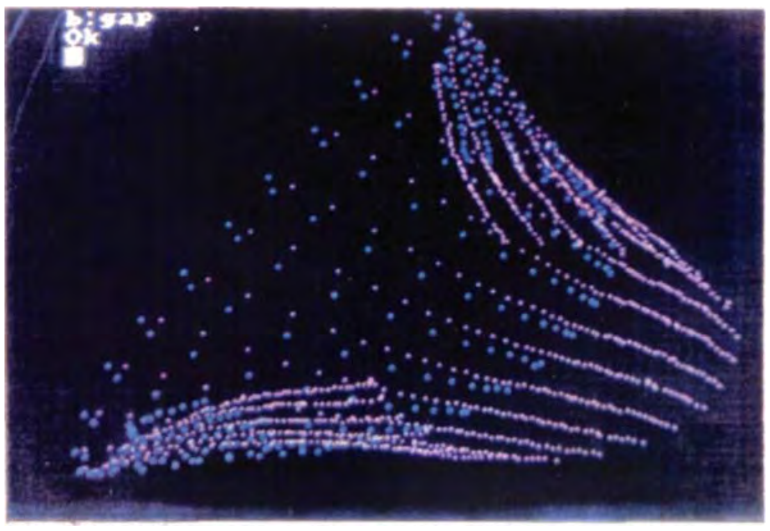
ATTRACTION AND REPULSION

To this point, the discussions and descriptions have dealt with single magnets, or single magnet arrangements and their fields. Now, we will present interactions between magnets, and show what really happens in attraction and repulsion.

Taking a ceramic magnet magnetized through the thickness we mount a curved metallic magnet over it and monitor the reacting fields in a one-half inch air gap. Study it carefully - the result may not be what you were expecting.
Notice first what happens in attraction;

We are all familiar with the pull of one magnet toward another. But, the mechanism is not visible, even if we use iron filings. What wc need to see is the activity of atomic particles that constitute the magnetic fields.

Our mapping operation shows these particles pairing off as the unlike fields merge.
Examine the illustration:

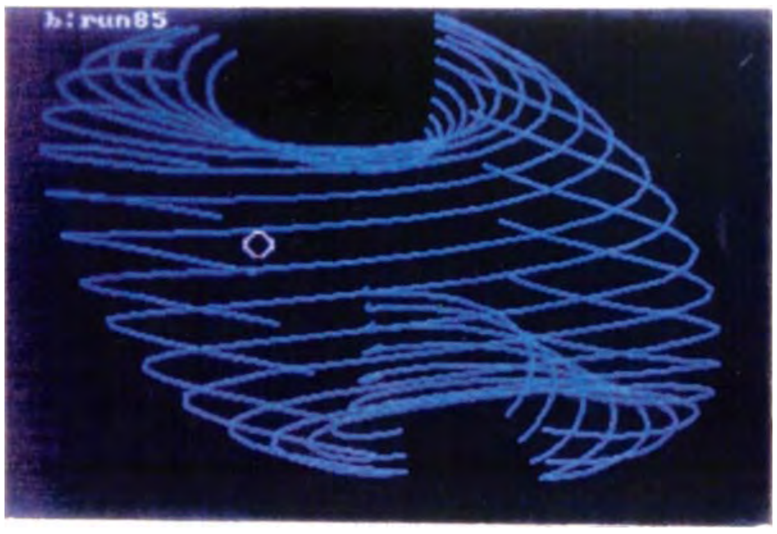


Then, our topographical program snows that the gauss count (the strength of the lines of force) at the attracting end has been reduced, because the pairing of a large part of the particle populations.

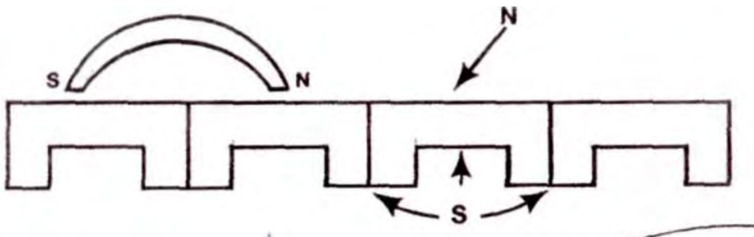
The repulsion of like poles represents particle activity which is quite different from attraction.

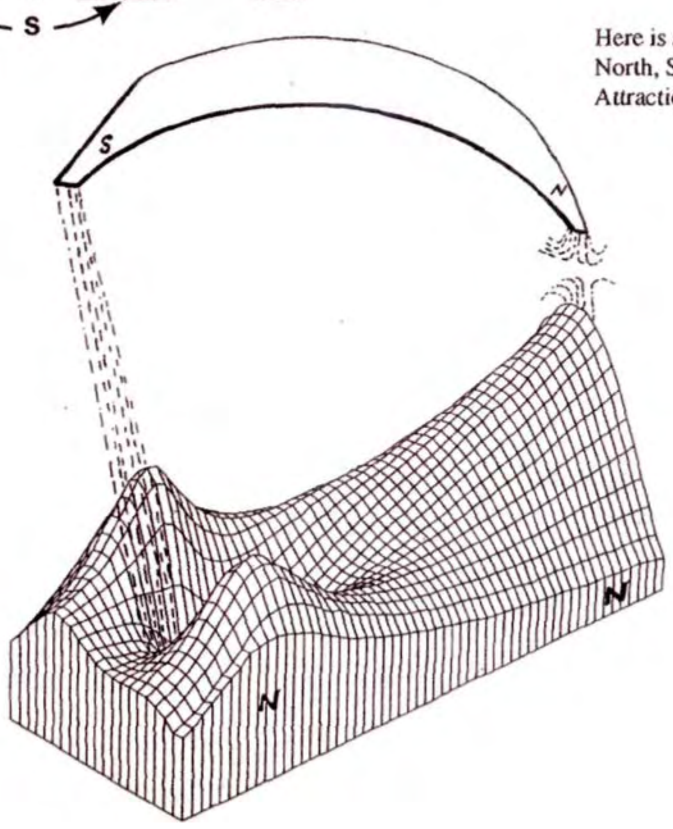
The particles react with each other as they form two vortices that spin in the same direction. There is no reduction in the gauss count, which registers about three times as high as it does at the attracting end.

Illustration:



The magnets used in the previous two illustrations, and the one that will follow, appear like this:



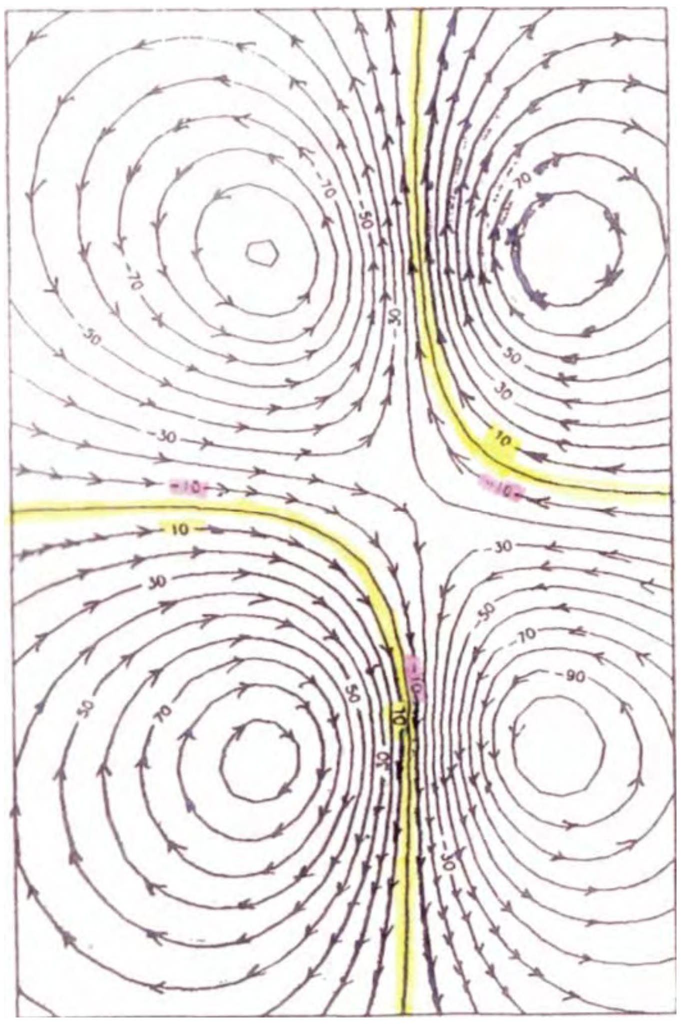


Here is a computer printout:
North, South Pole Differences
Attraction (L) Repulsion (R)

Notice how that (in the previous illustration) the south pole of the curved magnet bores a hole in the field below it. This beautifully illustrates the principles just started on attraction. Also, notice the repulsion, as it does not diminish the strength of the magnet mapped.

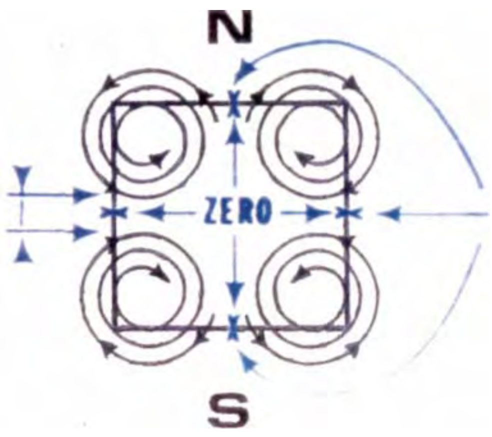
ATTRACTION and REPULSION of VORTICES WITHIN A MAGNET

This is a very unique area of interest. Notice the following topographical printout:



II you look carefully, you will seec that the vortices are separated by zerolines or dead space. The reason is the direction that the vortices spin. Illustration:

Lines of force going in the same direction REPEL



The vortices repulsion of each other causes spaces void of lines of force

Each vortex repels those next to it. Why? Magnetic lines of force going in the same direction repel. Notice that as the lines leave the poles, they are going the same direction, and therefore repel. And also, as they enter the sides, they enter going the same direction and repel each other. This leaves you a fine line in between vortices on the center of the magnet with no lines of force.

Another thing that is very interesting, though, is the fact that vortex spins in opposite corners (in the case of the stronger north element) attract each other. They can form a bond of continuous spins from corner to corner.

Notice the following illustration:

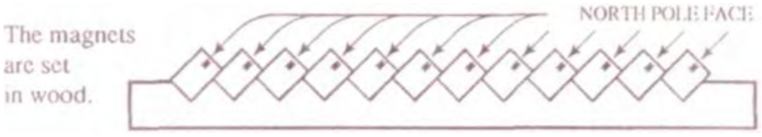
CORNER SPINS

Using the spins (vortex) of an individual corner of a magnet.

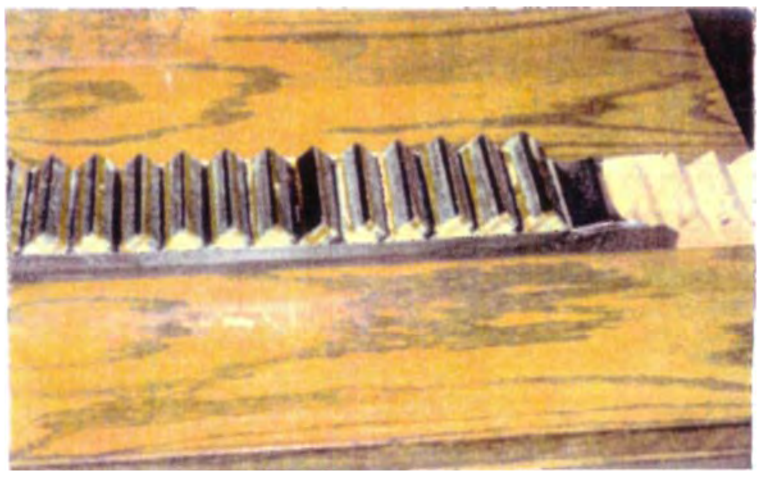
We now begin to discuss the arrangements of magnets designed for the purpose of doing work. The work is achieved by interactions between magnetic structures that cause one to drive the other.

The following structure uses a series of magnets with only one corner exposed so that the spins (vortex) of that corner only are (is) used to interact with the spins of a curved magnet, which is to be driven. Illustration:



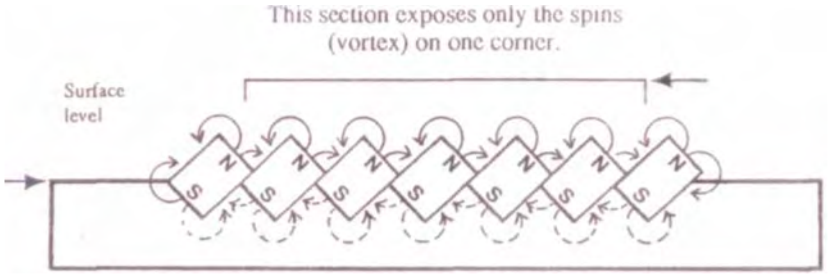
The magnets are set in wood.
NORTH POLE FACE

Actual photographs:



This picture shows the magnets in discussion in the foreground, and the mapping device in the background. (The 3-axis probe can be seen extended into the mapping area.)

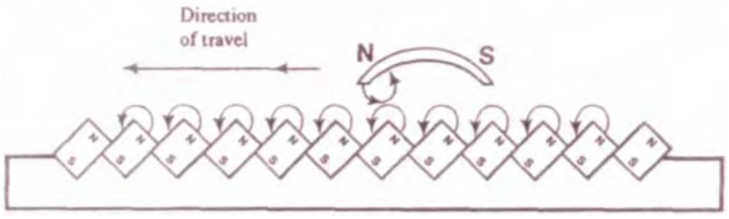
HERE IS A LARGER DEPICTION, SHOWING SPIN DETAIL.



This section exposes only the spins (vortex) on one corner.
Surface level
N
S

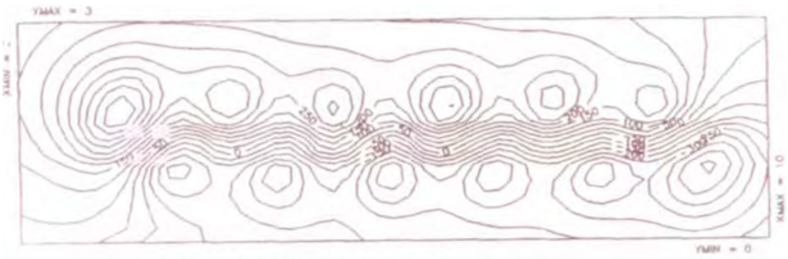
Notice that, within the structure, the only spin (or vortex) that is exposed, and affects anything above the magnets, is the one at the uppermost corner, the other north pole vortex is "shorted out", and the south pole vortices are below the structure.

Therefore, with this structure, and a curved magnet placed above it —

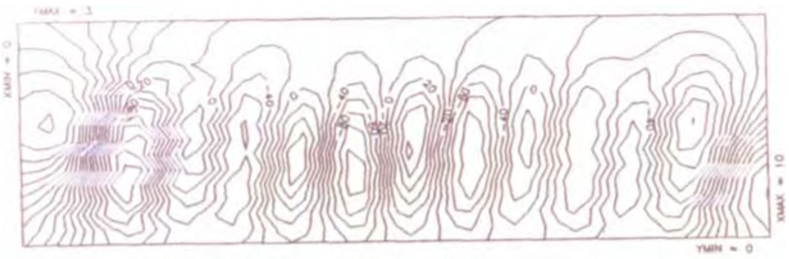


... the interacting spins, going in opposite directions, drive the curved magnet forward. This arrangement of the magnets greatly enhances the driving movement normally due to the right pulsing caused by simultaneous repulsion and attraction.

The pictures made by computer mapping show us that these comer spins tie knots in the lines of force, or make loops.

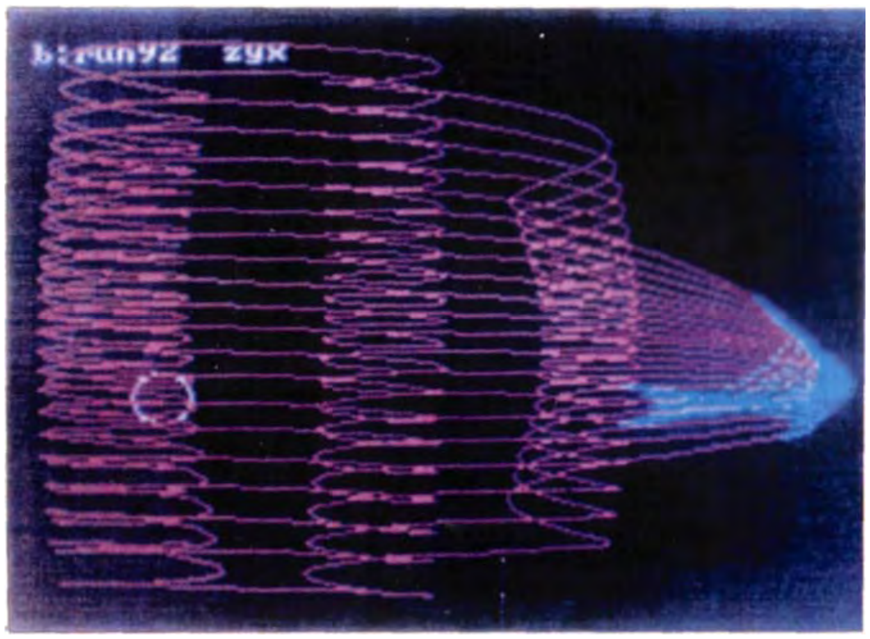


JAWS1 TRACK — RUN149 x axis



JAWS1 TRACK — RUN149 z axis

Here is how these spins register in this formation:



This is just one of the many ways that the magnetic field can be appropriated and used.

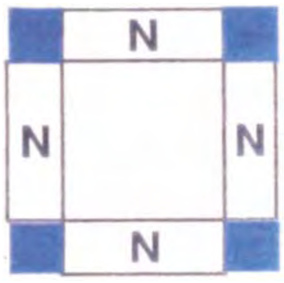
THE MAGNETIC GATE

One of the most radical new concepts due to the knowledge of the four spins (vortices) is the magnetic gate. (This is also an application designed for the use of doing work.)

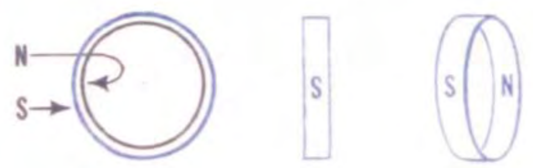
To anyone with a knowledge of physics, the thing about a "gate" that is fully radical is the fact that, in this case, a north magnetic field attracts a north pole. It will reject an approaching south pole.

This result, not anticipated by the physics books, shows how the spins in a magnet and the fields outside can be controlled. In this case, one set of spins and its field is shorted out and the other set takes over. The second set is going in a direction that will provide attraction despite the fact that the compass will register it as an opposing field.

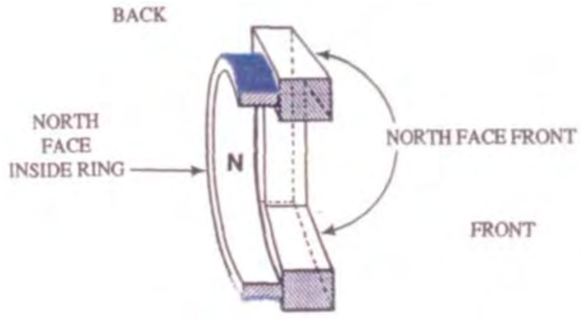
The gate is a complex arrangement of magnets. Its face is a square of four ceramic magnets magnetized through the thickness, with the north pole being the face for the whole square.



The back side of the gate is a ring of rubber magnet with the north pole on the inside face. This ring attracts to the back of the square. Illustration:

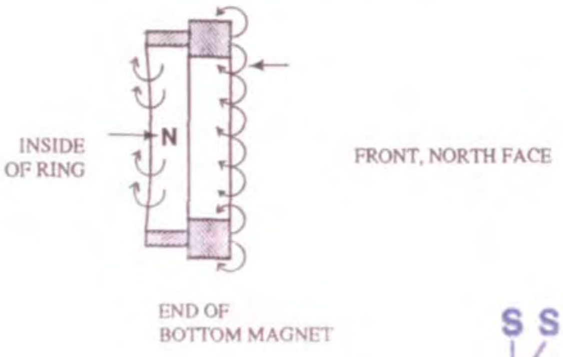


Here is a cross-section of the gate:



BACK
NORTH
FACE
INSIDE RING
N
NORTH FACE FRONT
FRONT

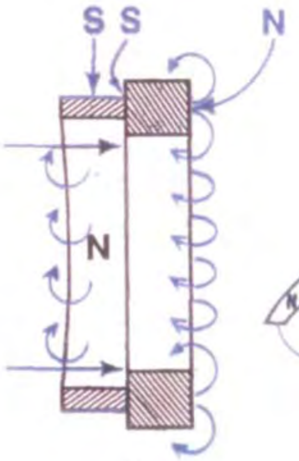
Another cross-section, to show the spins"



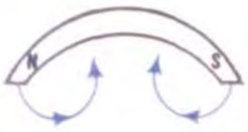
INSIDE
OF RING
N
FRONT, NORTH FACE
END OF
BOTTOM MAGNET

Only the front spins operate on the square; the spins on the back of the square, and the front of the ring, are shorted out.

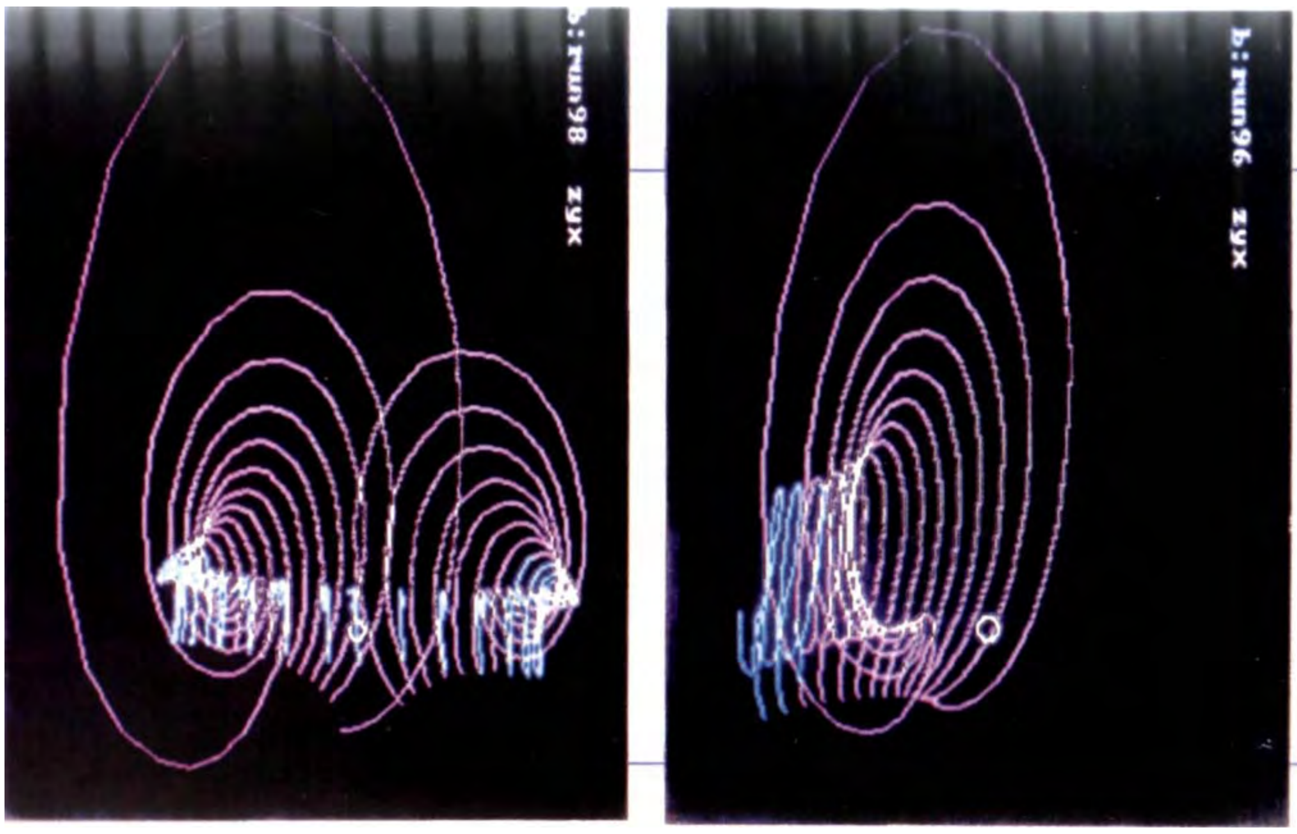
The south spin on the back of the square goes directly into the north face inside the ring behind.



The other spin of the ring's north inside is shorted out into the south back of the square.



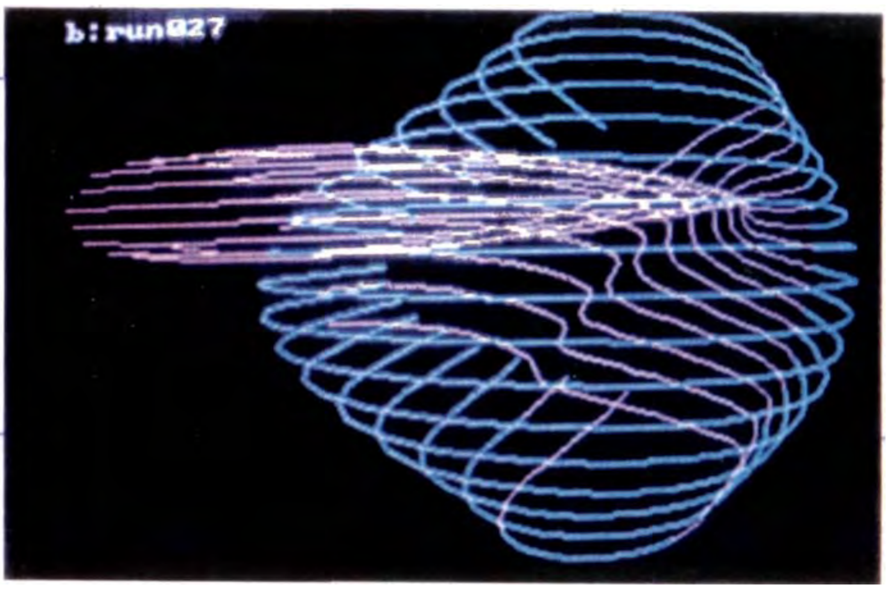
Since there are no back spins going the same direction as the leading north spin of the curved magnet, there is no repulsion. Because the spins of the gate are in the **opposite** direction of the lead north spin, there is **ATTRACTION of two north poles**, and therefore, the spins drive the curved magnet through the gate.



b:run98 zyx
b:run96 zyx

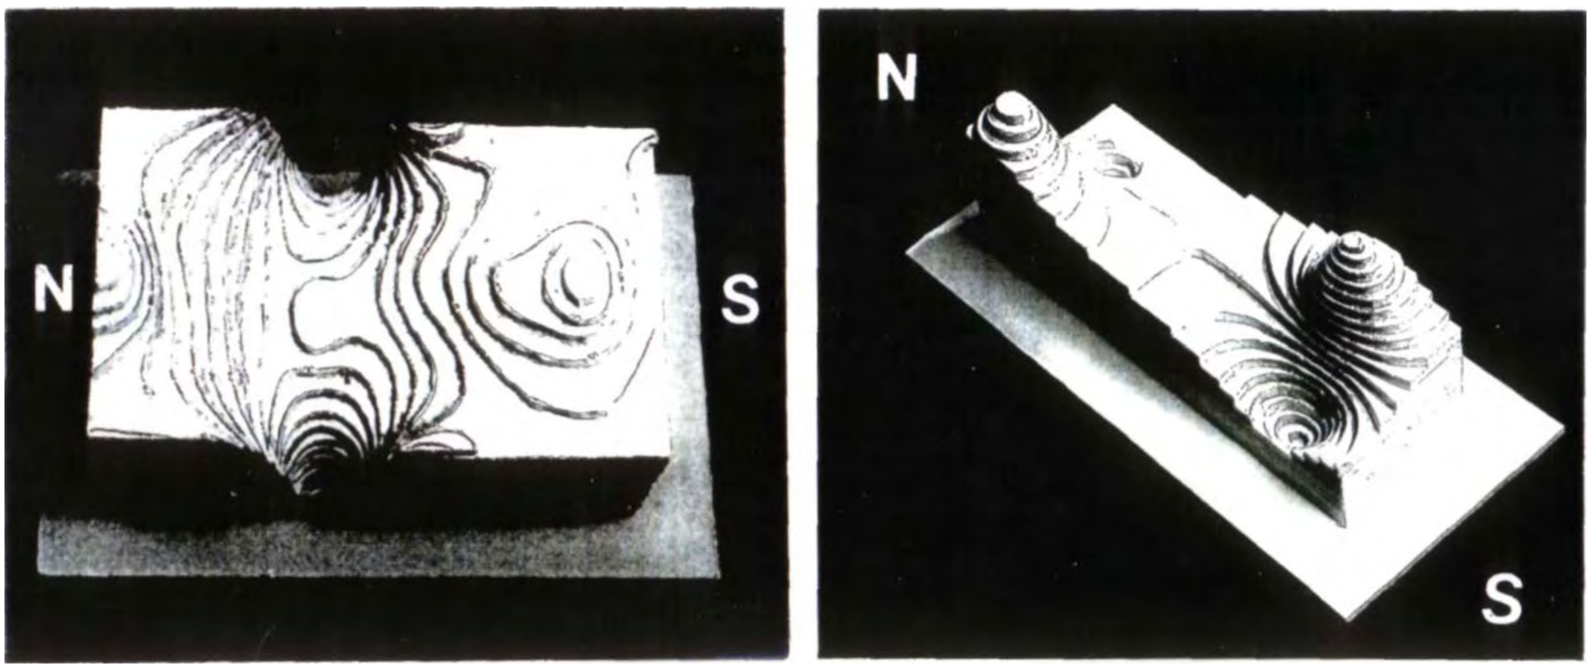
The computer beautifully pictures the spins in the sides of the gate that propel the curved metallic magnet through:

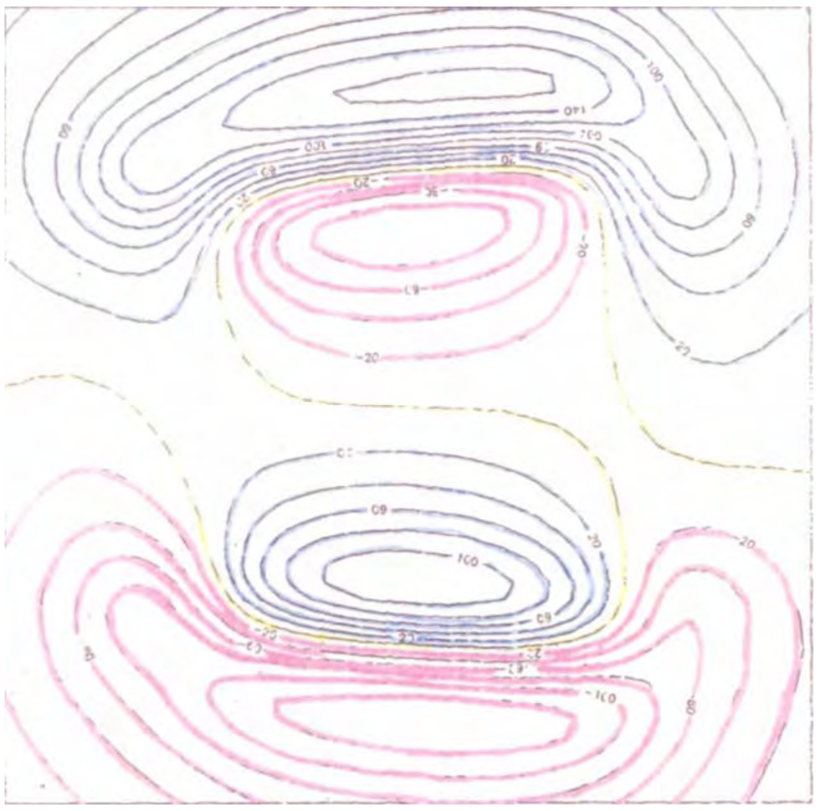
This picture is the interaction of the curved metallic magnet as it enters into the gate:



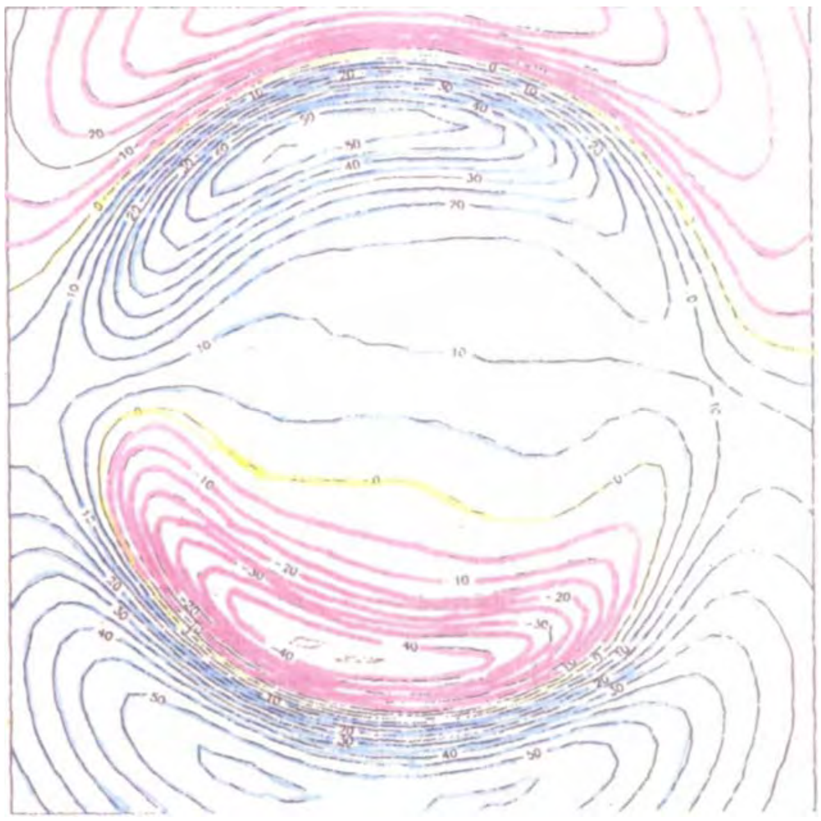
MORE ABOUT THE MAGNETIC GATE

This is a picture of a topographical model of the magnetic gate. The vortices on the sides, which enable the north magnet field to attract another north pole, arc the result of shorting out one set of spins in order to use the other set. The second set is going in a direction that will provide attraction despite the fact that the compass will register it as an opposing field. (Note: The gate's north magnetic field will reject an approaching south pole.)





FRONT GATE FACE (north)



REAR GATE FACE (south)

MAKING USE of the
TIME-ASYMMETRIC QUALITIES of PERMANENT MAGNETS

The following excerpts are from a paper by H. Zocher and C. Torok which concerns research done by these two men. The location where this work look place was Laboratorio da Producao Mineral, Ministerio da Agricultura, Rio de Janeiro, Brasil. E. P. Wigner communicated this Brazilian work to the Proceedings of the national Academy of Science on April 15, 1953.[1]

According to Zocher and Torok, the circularity of conductivity is a time-asymmetric property. Processes of conduction are not only lime-asymmetric, they are irreversible. One direction of time corresponds to the probable course, the other is improbable according to the second law of thermodynamics. Potential differences are time-symmetric. The circular asymmetry consists in the difference of resistance against the clockwise and counterclockwise currents, being probable or not. These currents are naturally time-asymmetric. Hence, a crystal structure, which is time-symmetric, cannot cause acircularly asymmetric conductivity. Such a property can be found only in a system with time-asymmetric circularity, with a mechanical or electrical rotation, with Coriolis forces or magnetic fields. The Hall effect corresponds indeed to circular electric conductivity, the RighiLeduc effect to a circular thermal conductivity, both produced by a magnetic field.[2]

The consideration of space-time asymmetry may prove to be useful outside the realm of crystal physics. The process of splitting a magnetic dipole into two free magnetic charges is seen to be impossible if one considers the space-time asymmetry involved in this process. Present-day literature is ambiguous concerning this point. Thus Dirac[3] discusses the reason why the separation of electric charges is so much easier than that of magnetic charges and Ehrenhaft believes to have succeeded in obtaining free magnetic charges.[4]

According to the given concept, a magnetic moment, and therefore a spin as well, always corresponds to a real circulating movement and cannot be considered as an intrinsic property without the character of movement. This reemphasizes the fact that static structures in three-dimensional space arc not adequate to represent the physical bodies and that the space-time relations are inevitable necessities.[5]

We shall speak of time symmetry if the time inversion has no influence upon the sign of the quality to be reversed.[6]

Asymmetry is much more than the counterpart of symmetry. Asymmetry indicates the existence of characteristic differences, whereas symmetry discards characteristic features. Certain physical phenomena are intrinsically related to certain types of asymmetry, whereas certain symmetry elements may exist without necessarily being related to those effects.[7] "C'est la dissimetric, qui cree le phenomene," stated P. Curie.[8]

THE MAPPING OF MAGNETIC FIELDS

To map a magnet's field the sensor must be moved between readings in a regular pattern. Two servomotors advance the Hall Effect sensor after each reading is taken to collect the 6000 needed data points.

To map a 3" X 7" area, taking readings every 0.1", requires over 2000 readings. This must be done three times to measure the X, Y, and Z components of the magnet's fields.

Each component is unique. X, Y, and Z can be looked at seperately, or combined as "magnitude," the square root of the sum of the squares of X, Y, and Z.

Topographic maps can be made of these magnetic fields, just as they can be made to show land contours.

Of particular interest are the null lines where the field changes sign or direction.

Complex assemblies of magnets can be designed to shield, focus, and distort magnetic fields for various purposes.

The Discovery of the Double Vortex

After predicting for years the presence of a vortex in the fields of permanent magnets, Steve Davis and I were working late one night with our three axis gauss meters and a new computer, mapping magnetic fields. I was starting to go home when he announced, "I don't know what I am doing, but I have something here that looks pretty linear."

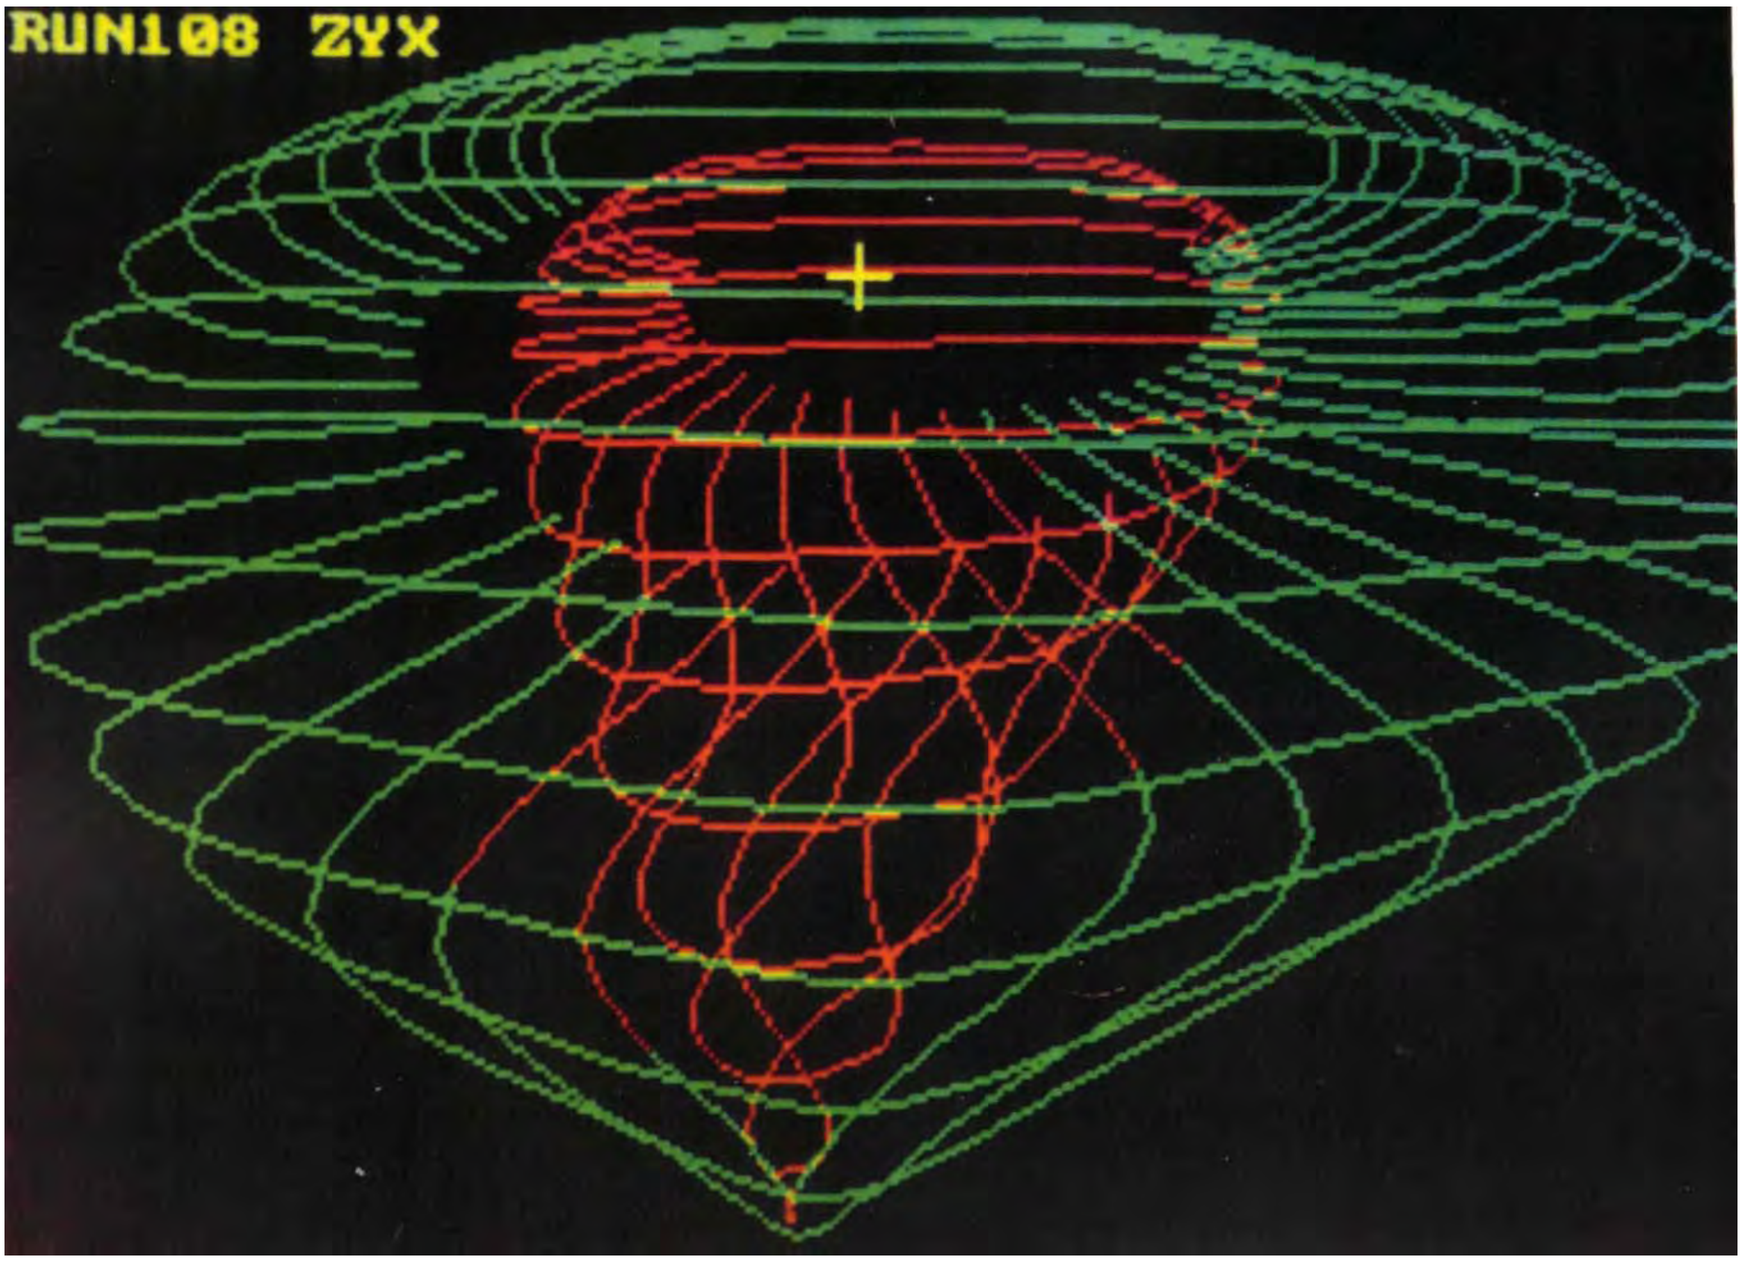
He proceeded to bring up on the screen, in living color, the forming of a double vortex. Not only was the double vortex there, but we could see as it formed, the opposite spins in such a perfect way. We knew that this had to be the beginning of something new and mighty important. The question now was, "How do we use it to the greatest advantage? How do we explain its importance to the patent structure that we have been developing for many years?"

We resorted to the libraries and studied many months to see what others had done. The results showed a great desert in this area.

Researchers, it seemed, had been content with the ancient iron filings as a mapping tool and had not used twentieth century methods to see what could be seen. The field had simply been ignored.

We ran a picture on the cover of National Laboratory but only the magazine seemed to sense the importance of it.

We have used our mapping methods to show the fields around a conductor, to show how a new generator works, to describe the thrust of permanent magnet units, and to explain our versatile gate discovery.



RUN108 ZYX

Amperian Currents

in Permanent Magnets

We are familiar with AC & DC electricity but we are not so familiar with Amperian currents in magnetic material. Yet, Ampere told us much about them over 150 years ago.

Today our magnetic materials are much better due to the rare earth usage. Fields of 35,000,000 Gauss Oersteds are available.

These Amperian currents are tightly wound in the material. They are firmly anchored so that they can not ordinarily be reversed. Thus, they should be available for many years of usage.

Three kinds of Amperian currents we have observed are:

1. The double vortex where opposite spins are found along side each other.
2. The double vortex where one vortex is inside the other.
3. The third form is the flat vortex.

Dr. Feynman recorded finding some of these in his Vol. 2 Physics lectures 37 - (12 - 13).

The interaction of the momentum of these currents is the basis of our patent work for the last number of years.

"Ampere was the first investigator to propose that the magnetism observed in permanent magnets is caused by tiny electric currents circulating within the molecules of magnetic material." Scientific American Jan. 89.

"Magnetism - more specifically ferromagnetism - in a material is associated with cooperative interactions between individual atoms tending to align the magnetic moments of those atoms parallel. The magnetic moment of an atom arises from the orbital and spin angular moments of its electrons. Only some elements have unpaired electrons - hence magnetic moments - and even fewer show the cooperative interaction necessary for ferromagnetism.

"A permanent magnet (PM) is a piece of a material that has stored within it magnetic energy - by alignment of magnetic moments - supplied by an electric field during the initial process of magnetization. The magnet retains this energy indefinitely - it is permanent. The material can be a metallic element, a metallic alloy, or even an oxide.

"There is a growing tendency to replace electromagnets by PMs because of major improvements in PM properties. The increasing cost of energy and the trend towards miniaturization are other reasons. The samarium-cobalt series of magnetic materials until recently provided the strongest PMs known. However, recent discoveries with alloy systems based on iron and neodymium promise even better performance.

"The two basic parameters used to define properties are the remanence, Br, and the coercivity, Hc, the vertical and horizontal axes respectively on the Lanthology diagram. The remanence arises from the cooperative alignment of magnetic moments. The coercivity measures the resistance to demagnetization of the material; a high value is essential in devices where the magnet will be subject to strong demagnetizing fields such as in motors.

"The coercivity depends not only on the underlying crystal structure but also on the microstructure of the material, on the domain morphology within the bulk magnet.

"Demagnetization is resisted when a large energy is needed to reverse the aligned magnetic moments within a crystallite. In some crystal structures certain directions - determined by the orbital moment of the minor component together with crystal-field effects and exchange interactions - provide an exceptional resistance. A great deal of energy will be required to reorient the magnetic moments from one easy direction to another. The crystal is said to have a high magnet-crystalline anisotropy.

"The role microstructure plays in giving high coercivity is related to the existence of domains - regions of common direction of magnetization - within a practical PM material. The movement of domain walls - separating domains - must be inhibited. This is often done by incorporation of another phase within the material. Much of the art of producing PMs lies in this microstructure control.

"The Neodymium-Iron systems, the latest and most powerful permanent magnets, seemingly provide the best yet approaches to the two mechanisms outlined above for high coercivity. They are being intensively studied by many research groups." "Neodymium, Iron, a Pinch of Boron and Permanent Magnets" Union Molycorp.

Visualizing Magnetic Fields

ABSTRACT

In unrestricted 3-space, what patterns would be seen if iron filings were not constrained by gravity to lie in a single plane? We have recorded magnetic field patterns and displayed them in a variety of ways: as 3-D surfaces; as contour maps; and as plots of two of the field components, with the third component's sign conferring color to the tip of the field vector. Our hope is that others may also find such patterns helpful in understanding magnetic phenomena.

One of Faraday's many contributions was his concept of force as traced by iron filings aligned on a glass plate above the poles of a magnet. However, the pattern is perhaps somewhat misleading since the iron filings can move only in the plane of the plate. In unrestricted 3-space, what patterns would be seen if the filings were not constrained by gravity to lie in a single plane, but could show the true direction of the magnetic vectors?

We measure the components of our magnetic field using three mutually-perpendicular indium arsenide semiconductors. Their Hall effect voltages are amplified, digitized, and recorded on a disk by an IBM personal computer. The probe containing the three semiconductors is accurately positioned by two servo motors which progressively scan the area above the poles in a series of small steps. The thousands of data points are then displayed in various ways.

What are the typical data and displays for a 6-inch Alnico magnet, shaped like a banana, having Nd-Fe-B pole pieces, each 1/8 x 5/16 x 1 inches?

The menu shown in Figure A summarizes such data. The area surveyed, 1/2 inch above the pole pieces, was 8.0 inches long by 2.0 inches wide. The sensor was moved in 1/10 inch steps to obtain 1701 data points for each component of the magnetic field. A Bell 620 gaussmeter amplified the voltages from the Hall effect sensors.
The signals were digitized by a Metrabyte interface board and recorded on a floppy disk. These data then served as input to our display programs.

Three-dimensional surface plots for the X (vertical), Y (horizontal), and Z (longitudinal) directions are shown in Figures B, C, and D, respectively. A typical contour, or topographic map, is shown in Figure E.

What good are these magnetic data? Are the 90 minutes necessary to obtain 5103 measurements well spent? We think that three distinct accomplishments are represented here.

First, we have learned to cope with the complexity of data acquisition using a personal computer, independent of dedicated, expensive mainframe time on a larger computer. The personal computer has made such activity affordable and efficient.

Second, we have learned to make contour plots and models which show the location of zero lines, where the field changes sign, or direction. Contour plots show also precipitous field changes where they occur, where the lines are closely spaced. Such data should prove helpful in the design of magnetic assemblies that can do unique tasks. By shading poles so they present an unsymmetrical structure when viewed relative to other magnetic components, unbalanced forces can be generated, causing motion in a preferred direction. Magnetic gates can be designed, and the optimum orientation of interacting magnets can be studied.

Third, we have made magnetic measurements that are accurate, reproducible, and easily stored for further review using a wide variety of display programs.

Using this method we have secured the following pictures:

1. The north and south poles of a curved magnet.
2. The picture of the fields around a current carrying wire.
3. The magnetic bullet formed in a permanent magnet railgun operation.

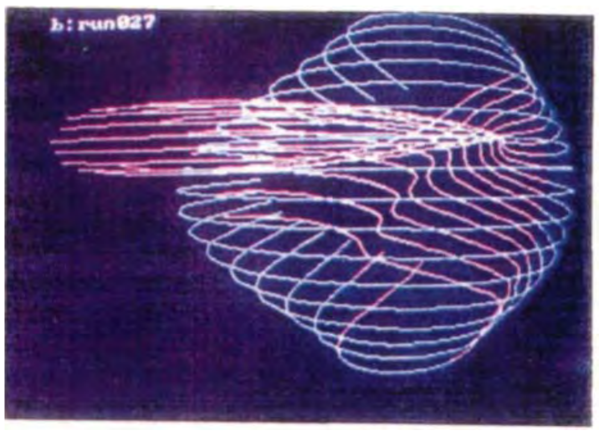
3. THE MAGNETIC BULLET FORMED IN A PERMANENT MAGNET RAILGUN OPERATION:



The Dynamo of Faraday and

The Piezomagnetic Dynamo

If a current is sent through a coil of wire between the poles of a large magnet, the coil will rotate. This is due to the directional magnetic field of the coil and the directional field of the magnet creating a squeeze effect in one direction.

The same action can be created by the reaction of two permanent magnet fields. A further refinement is to have the permanent magnet fields to attract one another until they are in a position where the fields are squeezed and the movement in the same direction is accelerated. This we call the piezomagnetic effect.

The secondary effect is also described as due to the quantum-mechanical exchange forces. Due to the squeeze effect, the spins become parallel instead of anti-parallel as they were in the original attraction. This molecular crowding is believed by some very good theorists to create an exchange force 1,000 times greater than
the purely attractive magnetic forces, we have noted this force for many years but did not have the explanation originally given by Heisenburg.

One thing we did notice was the fact that in a very strong field that a light armature did not run much faster than a unit that weighed four times that much.

Using the above method, we have constructed a strong shaded pole to attract a strong magnetic field into this intense magnetic field. Passing thru, this unit has developed effective thrust to accelerate the vehicle down a level track.

Carrying more than its own weight, the repeated actions of these cycling magnetic pressures have shown what a piezomagnetic effect can do.

It is a renewable energy source. Our maps of the fields show the forming of a composite magnetic field around the armature. This we have termed, the magnetic bullet. It is shown on the front cover of this book. We have entitled this activity THE PIEZOMAGNETIC RAILCAR because it is similar to the energy released by squeezing a piezoelectric crystal.

The crystal used does not get tired when used constantly; neither do the magnets, They will continue to generate the same amount of thrust as the car moves from section to section.

You have been reporting a number of defects in our society these days. How would you like to consider something completely new, something that is positive, not a tired rework of a current bit of knowledge or philosophy.

Applying our latest science to something considered old and established has shown how little we know about it. We have seen the vast sea of ignorance in which we swim. It has shown how the life long work of one individual can penetrate the layers of false concepts, learned superstitions, and degreed security blankets.

Not taking for granted some textbook conclusion, we have used direct methods of measuring that reveal big gaps in our storehouse of knowledge. Using this along with the belief that enough clues will enable you to catch a criminal, we have found that enough information lets you solve age old problems.

As we struggle to conserve and not to contaminate, it has given great comfort to find that we can do both. The goal is achievable.

Our new approaches are documented in three patent applications. Two of these have been granted and the third is pending.

As shown in our new book, we have found a way to shade the poles of permanent magnets, a way to make north poles attract north poles and reject south poles, a way to increase spin intensity and magnetic thrust, and a way to use the transfer forces to accelerate masses.

The resulting motor does not destroy its energy source. It is a reusable atomic source that is available world wide.

In biology, the discovery of the double helix and the genetic code has provided a tremendous fund of information.

In our case we have discovered a similar situation where we have the double vortex that occurs in all permanent magnet configurations.

The exploration of the genetic code by biologists with extensive government funding has begun.

We have just started the exploration of the double vortex and the magnetic code, but the fallout thus far has been extremely rewarding.

Note in the pictures, the mapped spins, the pictures of north poles attracting north poles and rejecting south poles, and the thrust developed by these units without any outside energy contribution.

[57] **ABSTRACT**

A method and apparatus for simulation of hearing in mammals by introduction of a plurality of microwaves into the region of the auditory cortex is shown and described. A microphone is used to transform sound signals into electrical signals which are in turn analyzed and processed to provide controls for generating a plurality of microwave signals at different frequencies. The multifrequency microwaves are then applied to the brain in the region of the auditory cortex. By this method sounds are perceived by the mammal which are representative of the original sound received by the microphone.

HEARING DEVICE

BACKGROUND OF THE INVENTION

1. Field of the Invention

This invention relates to devices for aiding of hearing in mammals. The invention is based upon the perception of sounds which is experienced in the brain when the brain is subjected to certain microwave radiation signals.

2. Description of the Prior Art

In prior art hearing devices for human beings, it is well known to amplify sounds to be heard and to apply the amplified sound signal to the ear of the person wearing the hearing aid. Hearing devices of this type are however limited to hearing disfunctions where there is no damage to the auditory nerve or to the auditory cortex. In the prior art, if there is damage to the auditory cortex or the auditory nerve, it cannot be corrected by the use of a hearing aid.

During World War II, individuals in the radiation path of certain radar installations observed clicks and buzzing sounds in response to the microwave radiation. It was through this early observation that it became known to the art that microwaves could cause a direct perception of sound within a human brain. These buzzing or clicking sounds however were not meaningful, and were not perception of sounds which could otherwise be heard by the receiver. This type of microwave radiation was not representative of any intelligible sound to be perceived. In such radar installations, there was never a sound which was generated which resulted in subsequent generation of microwave signals representative of that sound.

Since the early perception of buzzing and clicking, further research has been conducted into the microwave reaction of the brain. In an article entitled "Possible Microwave Mechanisms of the Mammalian Nervous System" by Philip L. Stocklin and Brain F. Stocklin, published in the TIT Journal of Life Sciences, Tower International Technomedical Institute, Inc. P.O. Box 4594, Philadelphia, Pa. (1979) there is disclosed a hypothesis that the mammalian brain generates and uses electro magnetic waves in the lower microwave frequency region as an integral part of the functioning of the central and peripheral nervous systems. This analysis is based primarily upon the potential energy of a protein integral in the neural membrane.

In an article by W. Bise entitled "Low Power Radio-Frequency and Microwave Effects On Human Electroencephalogram and Behavior", Physiol. Chemistry Phys. 10, 387 (1978), it is reported that there are significant effects upon the alert human EEG during radiation by low intensity CW microwave electromagnetic energy. Bise observed significant repeatable EEG effects for a subject during radiation at specific microwave frequencies.

SUMMARY OF THE INVENTION

Results of theoretical analysis of the physics of brain tissue and the brain/skull cavity, combined with experimentally-determined electromagnetic properties of mammalian brain tissue, indicate the physical necessity for the existence of electromagnetic standing waves, called modes in the living mammalian brain. The mode characteristics may be determined by two geometric properties of the brain; these are the cephalic index of the brain (its shape in prolate spheroidal coordinates)

and the semifocal distance of the brain (a measure of its size). It was concluded that estimation of brain cephalic index and semifocal distance using external skull measurements on subjects permits estimation of the subject's characteristic mode frequencies, which in turn will permit a mode by mode treatment of the data to simulate hearing.

This invention provides for sound perception by individuals who have impaired hearing resulting from ear damage, auditory nerve damage, and damage to the auditory cortex. This invention provides for simulation of microwave radiation which is normally produced by the auditory cortex. The simulated brain waves are introduced into the region of the auditory cortex and provide for perceived sounds on the part of the subject.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1** shows the acoustic filter bank and mode control matrix portions of the hearing device of this invention.

FIG. **2** shows the microwave generation and antenna portion of the hearing device of this invention.

FIG. **3** shows a typical voltage divider network which may be used to provide mode partition.

FIG. **4** shows another voltage divider device which may be used to provide mode partition.

FIG. **5** shows a voltage divider to be used as a mode partition wherein each of the resistors is variable in order to provide adjustment of the voltage outputs.

FIG. **6** shows a modified hearing device which includes adjustable mode partitioning, and which is used to provide initial calibration of the hearing device.

FIG. **7** shows a group of variable oscillators and variable gain controls which are used to determine hearing characteristics of a particular subject.

FIG. **8** shows a top view of a human skull showing the lateral dimension.

FIG. **9** shows the relationship of the prolate spherical coordinate system to the cartesian system.

FIG. **10** shows a side view of a skull showing the medial plane of the head, section A—A.

FIG. **11** shows a plot of the transverse electric field amplitude versus primary mode number M.

FIG. **12** shows a left side view of the brain and auditory cortex.

FIG. **13** shows the total modal field versus angle for source location.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

This invention is based upon observations of the physical mechanism the mammalian brain uses to perceive acoustic vibrations. This observation is based in part upon neuro anatomical and other experimental evidence which relates to microwave brain stimulation and the perception of sounds.

It is has been observed that monochromatic acoustic stimuli (acoustic tones, or single tones) of different frequencies uniquely stimulate different regions of the cochlea. It has also been observed that there is a corresponding one to one relationship between the frequency of a monochromatic acoustic stimulus and the region of the auditory cortex neurally stimulated by the cochlear nerve under the physiologically normal conditions (tonotopicity).

It is has been observed that for an acoustic tone of a frequency which is at the lower end of the entire acoustical range perceivable by a person, that a thin lateral region ("Line") parallel to the medial axis of the brain and toward the inferior portion of the primary auditory cortex is stimulated. For an acoustic tone whose frequency is toward the high end of the entire perceivable acoustic range, a thin lateral region parallel to the medial axis and toward the superior portion of the primary auditory cortex is stimulated.

Neural stimulation results in the generation of a broad band of microwave photons by the change in rotational energy state of protons integral to the neuron membrane of the auditory cortex. The physical size and shape of the brain/skull cavity, together with the (semiconductor) properties (conductivity and dielectric constant) of the brain tissue provide an electromagnetic resonant cavity. Specific single frequencies are constructively reinforced so that a number of standing electromagnetic waves, each at its own single electromagnetic frequency in the microwave frequency region, are generated in the brain. Each such standing electromagnetic wave is called a characteristic mode of the brain/skull cavity.

Analysis in terms of prolate spheroidal wave functions indicates that transverse electric field components of these modes have maxima in the region of the auditory cortex. This analysis further shows that transverse electric field possess a variation of amplitude with angle in the angular plane (along the vertical dimension of the auditory cortex) and that is dependent only upon the primary mode number.

The auditory cortex in the normally functioning mammalian brain is a source of microwave modes. The auditory cortex generates these modes in accordance with the neural stimulation of the auditory cortex by the cochlear nerve. Mode weighting for any one acoustic tone stimulus is given by the amplitude of each mode along the line region of the auditory cortex which is neurally stimulated by that acoustic tone stimulus. A listing of mode weighting versus frequency of acoustic stimulus is called the mode matrix.

In this invention, the functions of the ear, the cochlear nerve, and the auditory cortex are simulated. Microwaves simulating the mode matrix are inserted directly into the region of the auditory cortex. By this insertion of simulated microwave modes, the normal operation of the entire natural hearing mechanism is simulated.

Referring now to FIG. 1 and FIG. 2 there is shown an apparatus which provides for induced perception of sound into a mammalian brain. This hearing device includes a microphone **10** which receives sounds, an acoustic filter bank **12** which separates the signals from the microphone into component frequencies, and a mode control matrix **14** which generates the mode signals which are used to control the intensity of microwave radiations which are injected into the skull cavity in the region of the auditory cortex.

The acoustic filter bank **12** consists of a bank of acoustic filters F1 through Fk which span the audible acoustic spectrum. These filters may be built from standard resistance, inductance, and capacitance components in accordance with well established practice. In the preferred embodiment there are 24 filters which correspond to the observed critical bandwidths of the human ear. In this preferred embodiment a typical list of filter parameters is given by Table 1 below:

TABLE I

Filter No.	Center Frequency (Hz)	Bandwidth (Hz)
1	50	less than 100
2	150	100
3	250	100
4	350	100
5	450	110
6	570	120
7	700	140
8	840	150
9	1,000	160
10	1,170	190
11	1,370	210
12	1,600	240
13	1,850	280
14	2,150	320
15	2,500	380
16	2,900	450
17	3,400	550
18	4,000	700
19	4,800	900
20	5,800	1,100
21	7,000	1,300
22	8,500	1,800
23	10,500	2,500
24	13,500	3,500

The rectifier outputs one through K are feed to K mode partition devices. The mode partitioning devices each have N outputs wherein N is the number of microwave oscillators used to generate the microwave radiation. The outputs **1** through N of each mode partition device is applied respectively to the inputs of each gain controlled amplifier of the microwave radiation generator. The function of the mode control matrix **14** is the control of the microwave amplifiers in the microwave amplifier bank **18**. In the preferred embodiment thus will be 24 outputs and 24 microwave frequency oscillators.

Connected to each microwave amplifier gain control line is a mode simulation device **16** which receives weighted mode signals from the mode partition devices **14**. Each mode simulation device consists of one through k lines and diodes **17** which are each connected to summing junction **19**. The diodes **17** provide for isolation from one mode partition device to the next. The diodes **17** prevent signals from one mode partition device from returning to the other mode partition devices which are also connected to the same summing junction of the mode summation device **16**. The diodes also serve a second function which is the rectification of the signals received from the acoustic filter bank by way of the mode partition devices. In this way each mode partition device output is rectified to produce a varying DC voltage with major frequency components of the order of 15 milliseconds or less. The voltage at the summation junction **19** is thus a slowly varying DC voltage.

The example mode partition devices are shown in greater detail in FIGS. **3**, **4**, and **5**. The mode partition devices are merely resistance networks which produce **1** through N output voltages which are predetermined divisions of the input signal from the acoustic filter associated with the mode partition device. FIG. **3** shows a mode partitioning device wherein several outputs are associated with each series resistor **30**. In the embodiment depicted in FIG. **4** there is an output associated with each series resistor only, and thus there are N series resistors, or the same number of series resistors as there are outputs. The values of the resistors in the mode partition resistor network are determined in accordance with the magnitudes of the frequency component from the acoustic filter bank **12** which is required at the summation point **19** or the gain control line for amplifiers **20**.

The microwave amplifier bank **18** consists of a plurality of microwave oscillators **1** through N each of which is connected to an amplifier **20**. Since the amplifiers **20** are gain controlled by the signals at summation junction **19**, the magnitude of the microwave output is controlled by the mode control matrix outputs F1 through F_n. In the preferred embodiment there are 24 amplifiers.

The leads from the microwave oscillators **1** through N to the amplifiers **20** are shielded to prevent cross talk from one oscillator to the next, and to prevent stray signals from reaching the user of the hearing device. The output impedance of amplifiers **20** should be 1000 ohms and this is indicated by resistor **21**. The outputs of amplifiers **20** are all connected to a summing junction **22**. The summing junction **22** is connected to a summing impedance **23** which is approximately 50 ohms. The relatively high amplifier output impedance **21** as compared to the relatively low summing impedance **23** provides minimization of cross talk between the amplifiers. Since the amplitude of the microwave signal needed at the antenna **24** is relatively small, there is no need to match the antenna and summing junction impedances to the amplifier **20** output impedances. Efficiency of the amplifiers **20** is not critical.

Level control of the signal at antenna **24** is controlled by pick off **25** which is connected to the summing impedance **23**. In this manner, the signal at antenna **24** can be varied from 0 (ground) to a value which is acceptable to the individual.

The antenna **24** is placed next to the subject's head and in the region of the subject's auditory cortex **26**. By placement of the antenna **24** in the region of the auditory cortex **26**, the microwave field which is generated simulates the microwave field which would be generated if the acoustic sounds were perceived with normal hearing and the auditory cortex was functioning normally.

In FIG. **2A** there is shown a second embodiment of the microwave radiation and generator portion of the hearing device. In this embodiment a broad band microwave source **50** generates microwave signals which are feed to filters **52** through **58** which select from the broad band radiation particular frequencies to be transmitted to the person. As in FIG. **2**, the amplifiers **20** receive signals on lines **19** from the mode control matrix. The signals on lines **19** provide the gain control for amplifiers **20**.

In FIG. **6** there is shown a modified microwave hearing generator **60** which includes a mode partition resistor divider network as depicted in FIG. **5**. Each of the mode partition voltage divider networks in this embodiment are individually adjustable for all of the resistances in the resistance network. FIG. **5** depicts a voltage division system wherein adjustment of the voltage partition resistors is provided for.

In FIG. **6**, the sound source **62** generates audible sounds which are received by the microphone of the microwave hearing generator **60**. In accordance with the operation described with respect to FIGS. **1** and **2**, microwave signals are generated at the antenna **10** in accordance with the redistribution provided by the mode control matrix as set forth in FIG. **5**.

The sound source **62** also produces a signal on line **64** which is received by a head phone **66**. The apparatus depicted in FIG. **6** is used to calibrate or fit a microwave hearing generator to a particular individual. Once the hearing generator is adjusted to the particular individual by adjustment of the variable resistors in the adjustable mode partition portion of the hearing generator, a second generator may be built using fixed value resistors in accordance with the adjusted values achieved in fitting the device to the particular subject. The sound produced by headphone **66** should be the same as a sound from the sound source **62** which is received by the microphone **10** in the microwave hearing generator **60**. In this way, the subject can make comparisons between the perceived sound from the hearing generator **60**, and the sound which is heard from headphone **66**. Sound source **62** also produces a signal on **68** which is feed to cue light **69**. Cue light **69** comes on whenever a sound is emitted from sound source **62** to the microwave generator **60**. In this manner, if the subject hears nothing, he will still be informed that a sound has been omitted and hence that he is indeed perceiving no sound from the microwave hearing generator **60**.

In FIG. **7** there is shown a modified microwave hearing generator which may be used to determine a subject's microwave mode frequencies. In this device, the acoustic filter bank and the mode control matrix have been removed and replaced by voltage level signal generated by potentiometers **70**. Also included are a plurality of variable frequency oscillators **72** which feed microwave amplifiers **74** which are gain controlled from the signal generated by potentiometers **70** and pick off arm **76**.

This modified microwave hearing generator is used to provide signals using one oscillator at a time. When an oscillator is turned on, the frequency is varied about the estimated value until a maximum acoustic perception by the subject is perceived. This perception however may consist of a buzzing or hissing sound rather than a tone because only one microwave frequency is being received. The first test of perception is to determine the subject's lowest modal frequency for audition ($M=1$). Once this modal frequency is obtained, the process is repeated for several higher modal frequencies and continued until no maximum acoustic perception occurs.

Another method of determination of a subject's modal frequencies is through anatomical estimation. This procedure is by measurement of the subject's cephalic index and the lateral dimensions of the skull. In this method, the shape is determined in prolate spheroidal coordinance.

Purely anatomical estimation of subject's modal frequencies is performed by first measuring the maximum lateral dimension (breadth) L FIG. **8**, of the subject's head together with the maximum dimension D (anterior to posterior) in the medial plane of the subject's head. D is the distance along Z axis as shown in FIG. **10**. The ratio L/D, called in anthropology the cephalic index, is monotonically related to the boundary value ξ_o defining the ellipsoidal surface approximating the interface between the brain and the skull in the prolate spheroidal coordinate system. ξ_o defines the shape of this interface; ξ_o and D together give an estimate of a, the semi-focal distance of the defining ellipsoid. Using ξ_o and a, together with known values of the conductivity and dielectric constants of brain tissue, those wavelengths are found for which the radial component of the electric field satisfies the boundary condition that it is zero at ξ_o.

These wavelengths are the wavelengths associated with the standing waves or modes; the corresponding frequencies are found by dividing the phase velocity of microwaves in brain tissue by each of the wavelengths.

A subject's microwave modal frequencies may also be determined by observing the effect of external microwave radiation upon the EEG. The frequency of the M equal 1 mode may then be used as a base point to estimate all other modal frequencies.

A typical example of such an estimation is where the subject is laterally irradiated with a monochromatic microwave field simultaneous with EEG measurement and the microwave frequency altered until a significant change occurs in the EEG, the lowest such frequency causing a significant EEG change is found. This is identified as the frequency of the $M=1$ mode, the lowest mode of importance in auditory perception. The purely anatomical estimation procedure (FIGS. **8**, **9**, **10**) is then performed and the ratio of each modal frequency to the $M=1$ modal frequency obtained. These ratios together with the experimentally-determined $M=1$ frequency are then used to estimate the frequencies of the mode numbers higher than 1. The prolate spheroidal coordinate system is shown in FIG. **9**. Along the lateral plane containing the x and y coordinates of FIG. **9**, the prolate spheroidal coordinate variable ϕ (angle) lies FIGS. **9** and **10**. Plots of the transverse electric field amplitude versus primary mode number m are shown in FIG. **11**. The equation is

$$E_{transverse}(m, \phi) = E_0 \sin(m\ \phi)$$

The "elevation view" FIG. **12**, of the brain from the left side, shows the primary auditory cortex **10**. The isotone lines and the high frequency region are toward the top of **100** and the low frequency region toward the bottom of **100**.

The formula I, set forth below is the formula for combining modes from an iso-tone line at $\phi=\phi j$ being excited to obtain the total modal field at some other angular location ϕ. For this formula, if we let $J=1$ (just one iso-tone single frequency acoustic stimulus line), then it can be shown that ALL modes (in general) must be used for any ONE tone.

FORMULA I
RMS TRANSVERSE ELECTRIC FIELD IN ANGULAR PLANE, $f(0)$

$$f(0) = \left[\sum_{m=1}^{M} \Bigg(\Bigg\{ \sin(m0) \cdot \sum_{j=1}^{J} e^{-(0-0j)/\Delta 0m} \sin(m0_j) \Bigg) \Bigg\}^{2} \right]^{\frac{1}{2}}$$

ϕ=ANGLE (0° LATERAL)
ϕ_j=LOCATION OF j-TH SOURCE (TOTAL NUMBER J)
$\Delta\phi_m$=ATTENUATION LENGTH (IN ANGLE) OF m-TH MODE
m=PRIMARY MODE NUMBER (HIGHEST MODE M)

FIG. **13** shows the resulting total modal field versus angle ϕ for source location ϕ at 5.25°, 12.5°, etc. With reference to the set of curves at the left top of this figure. A spacing of approximately 7.25° in ϕ corresponds to a tonal difference of about 1 octave. This conclusion is based on the side-lobes of pattern coming from $\phi=5.25°$, etc. The total filed (value on y-axis) falls considerably below the top curves for source locations well below 5.25° (toward the high acoustic stimulus end) and also as the source of frequency goes well above 30° (low frequency end). ϕ is plotted positive downward from 0° at lateral location as indicates in FIG. **11**.

Resistor weightings are obtained from the $|\sin(m[\phi-\phi j])|$, Formula I. The scale between acoustic frequency and ϕ must be set or estimated from experiment. Approximately $5.25 \pm 1°$ corresponds to a tonal stimulus at about 2 kHz (the most sensitive region of the ear) since this source location gives the highest electric field amplitude.

The apparatus of FIG. **7** may also be used to determine values for a hearing device which are required for a particular subject. Once the modal frequencies have been estimated, the device of FIG. **7** which includes variable microwave oscillators may be used to determine values for the oscillators which match the subject, and to determine resistance values associated with the mode partition devices of the mode control matrix.

In FIG. **7** manual control of the amplifier gain is achieved by potentiometers **76**. In this manner the amplifier gains are varied about the estimated settings for an acoustic tone stimulus in the region of two thousand Hertz (2 kHz) until maximum acoustic perception and a purest tone are achieved together. The term purest tone may also be described as the most pleasing acoustic perception by the subject. This process may be repeated at selected frequencies above and below 2 kHz. The selected frequencies correspond to regions of other acoustic filter center frequencies of the subject. When modal frequency (oscillator frequency) and gain set values (setting a potentiometer **76**) are noted, it is then possible to calculate fixed oscillator frequencies and control resistor values for the adjusted hearing device for this particular subject.

In the event the subject has no prior acoustic experience, that is deaf from birth, estimated resistor values must be used. Also, a complex acoustic stimulation test including language articulation and pairs of harmonically related tones may be developed to maximize the match of the hearing device parameters for those of this particular subject.

Typical components for use in this invention include commercially available high fidelity microphones which have a range of 50 Hz to 15 kHz with plus or minus 3 dB variation.

The audio filters to be used with the acoustic filter bank **12** are constructed in a conventional manner, and have Q values of about 6. The filters may also be designed with 3 dB down points (½ the bandwidth away from the center frequency) occurring at adjacent center frequency locations.

The diodes **17** in the mode control matrix which provide isolation between the mode partition circuits are commercially available diodes in the audio range.

The microwave oscillators **1** through N and the microwave amplifiers **20** are constructed with available microwave transistors which can be configured either as oscillators or amplifiers. Examples of the transistors are GaAsFET field effect transistors by Hewlitt Packard known as the HFET series or silicone bipolar transistors by Hewlitt Packard known as the HXTR series.

All the cable between the oscillators, the microwave amplifiers, and the antenna should be constructed with either single or double shielded coaxial cable.

The antenna **24** for directing microwave signals to the audio cortex **26** should be approximately the size of the auditory cortex. A typical size would be one and one half CM high and one half to one CM wide. The antenna as shown is located over the left auditory cortex, but the right may also be used. Since the characteristic impedance of the brain tissue at these microwave frequencies is close to 50 ohms, efficient transmission by commercially available standard 50 ohm coax is possible.

The invention has been described in reference to the preferred embodiments. It is, however, to be understood that other advantages, features, and embodiments may be within the scope of this invention as defined in the appended claims.

What is claimed is:

1. A sound perception device for providing induced perception of sound into a mammalian brain comprising in combination:

means for generating microwave radiation which is representative of a sound to be perceived, said means for generating including means for generating a simultaneous plurality of microwave radiation frequencies and means for adjusting the amplitude of said microwave radiation frequencies in accordance with the sound to be perceived; and

antenna means located in the region of the auditory cortex of said mammalian brain for transmitting said microwave energy into the auditory cortex region of said brain.

2. A hearing device for perception of sounds comprising in combination:

means for generating a signal representative of sounds;

means for analyzing said signal representative of said sounds having an output;

means for generating a plurality of microwave signals having different frequencies having a input connected to said output of said means for analyzing said signals, having an output;

means for applying said plurality of microwave signals to the head of a subject, and

whereby the subject perceives sounds which are representative of said sounds.

3. The apparatus in accordance with claim 2 wherein said means for generating a signal is a microphone for detecting sound waves.

4. The apparatus in accordance with claim 2 wherein said means for applying said plurality of microwave signals is an antenna.

5. The apparatus in accordance with claim 4 wherein said antenna is placed in the region of the auditory cortex of the subject.

6. The apparatus in accordance with claim 2 wherein the subject is a human being.

7. The apparatus in accordance with claim 2 wherein said means for analyzing said signal comprises:

an acoustic filter bank for dividing said sounds into a plurality of component frequencies; and

a mode control matrix means for providing control signals which are weighted in accordance with said plurality of component frequencies, having an output connected to said means for generating a plurality of microwave signal inputs.

8. The apparatus in accordance with claim 7 wherein said acoustic filter bank includes a plurality of audio frequency filters.

9. The apparatus in accordance with claim 8 wherein said audio frequency filters provide a plurality of output frequencies having amplitudes which are a function of said signal representative of sounds.

10. The apparatus in accordance with claim 9 wherein said amplitudes are the weighted in accordance with transform function of the signal representative of sounds.

11. The apparatus in accordance with claim 7 wherein said mode control matrix device includes a voltage divider connected to each of said plurality of said audio frequency filters.

12. The apparatus in accordance with claim 11 wherein each of said voltage dividers has a plurality of outputs which are connected in circuit to said means for generating a plurality of microwave signals.

13. The apparatus in accordance with claim 2 wherein said means for generating a plurality of microwave signals comprises a plurality of microwave generators each having a different frequency and means for controlling the output amplitude of each of said generators.

14. The apparatus in accordance with claims 2 wherein said means for generating a plurality of microwave signals comprises a broad band microwave source and a plurality of filters.

15. The apparatus in accordance with claim 13 wherein said generators each comprise a microwave signal source and a gain controlled microwave amplifier.

16. The apparatus in accordance with claim 13 wherein said means for analyzing output is connected to said means for controlling microwave amplifier output amplitudes.

17. The apparatus in accordance with claim 13 wherein analyzing includes K audio frequency filters.

18. The apparatus in accordance with claim 17 wherein there are N microwave generators.

19. The apparatus in accordance with claim 18 including a mode partitioning means which provides N outputs for each of said K audio frequency filters.

20. The apparatus in accordance with claim 19 wherein said N amplifiers each have K inputs from said mode partitioning means.

21. The apparatus in accordance with claim 20 wherein said N amplifiers have K inputs less the mode partitioning means outputs which are so small that they may be omitted.

22. The apparatus in accordance with claim 20 wherein said mode partitioning output device outputs each include a diode connected to each microwave amplifier gain control to provide isolation between all outputs.

23. The apparatus in accordance with claim 20 wherein said K audio frequency filters are chosen to correspond to the critical bandwidths of the human ear.

24. The apparatus in accordance with claim 20 wherein said N microwave generators are each adjustable in frequency output.

25. The apparatus in accordance with claim 18 wherein the frequency of each N microwave generators is determined by anatomical estimation.

26. The apparatus in accordance with claim 18 wherein the frequency of the lowest frequency microwave generator is chosen by determination of the effect of external microwave generation on the EEG of the subject.

27. The apparatus in accordance with claim 18 wherein the frequency of each of said N microwave generators corresponds to the subject's microwave modal frequencies.

28. The apparatus in accordance with claim **27** wherein the subject's modal frequencies are determined by measurement of the subject's cephalic index and the lateral dimensions of the skull.

29. The apparatus in accordance with claim **28** wherein the subject's lowest modal frequency is determined by varying the frequency of the lowest frequency microwave generator about the estimated value until a maximum acoustic perception is obtained by the subject.

Physical Immortality – Two Powerful Words

by

Leonard Orr

A mind expanded by a new idea can never return to its former size. Two common words in everyone's vocabulary when combined into one idea become one of the most powerful ideas in the universe. Physical is a very common word. Immortality is also a common word. When you combine them, you get the idea of physical immortality. I've been exposing people to the idea of physical immortality for over 30 years.

Physical immortality means victory over physical death. It means body and mind mastery. Our Spirit is already an immortal master. This simple thought of physical immortality makes us realize that although death may be popular, it is not inevitable. Physical death is optional. The whole purpose of Jesus Christ was to teach us this. But Jesus was not the first nor the last human to conquer death. The Hebrew Bible is about five main immortal humans: Elijah, Moses, Melchizadek, and Enoch. In the beginning of Bible history, everyone lived 500 to 1000 years. India has its immortal yogis. Every continent has its favorite immortals, including native Americans. I've made this one of my favorite research projects for 37 years. Why do Christians die? Why? If Jesus died to save us from sin and death?

The founders and heroes and heroines of most religions who conquered death do not have a local address on planet Earth. When I learned about the immortal yogis who do, I was so excited I couldn't wait to meet them. Since my first trip to India in 1977, I have met over 8 immortals who each have maintained their body for at least 300 years. People have to be at least 300 to qualify for my research. I know of many more that I haven't had a chance to meet yet.

I've met several who are over 2000. These are yogis who have maintained a local address on planet Earth for over 2000 years. I've written books about two of them: Babaji and Bhartriji. People often tell me that after my lecture or book in which the idea of physical immortality got their attention, they couldn't stop thinking about it for several years. It makes so much sense. How could people be blinded by the death is inevitable belief system for so long?

After teaching the truth about physical immortality for over 30 years, I've concluded that the reason people don't like to know about it is because it I involves a little spiritual work and personal changes. Physical immortality is the natural result of a mind filled with wisdom and aliveness.

The three basic causes of death are:

1. ignorance

2. emotional energy pollution

3. poor diet.

Therefore, to master death you have to do three things:

1. Master the idea of physical immortality, which involves living from Spirit, our natural divinity.

2. Unravel our own death urge, which we received from our parents and encourage all the people in our environment to do the same. Learn how to keep our energy body & emotional mind clean and balanced through spiritual purification practices.

3. Learn the power of nutrition and fasting and the other simple and pleasurable habits that give us body mastery. Becoming a vegetarian is basic!

Mastering spiritual practices is less difficult than living a miserable life that leads to the grave. In fact, true spiritual practices are the ultimate pleasures and enrich all the pleasures of living. As I studied the lives of my immortal yogi friends, I began to realize that becoming an immortal yogi is not difficult; it just takes a different focus. People die because they kill themselves.

The greatest enemy of mankind has been and always will be ignorance. And the most evil form of ignorance is self-righteousness – thinking we know enough. Self-righteous people are murdering their own natural divinity and are guilty of murdering the natural divinity of everyone around them. It is the sin of eating of the fruit of the tree of knowledge and naturally yields the personal doom of death. The Bible says, "God is not willing for any to perish, but that all should come to a knowledge of repentance." Repentance means to change our mind. Repentance is neither difficult nor unpleasurable. In fact, it is exciting, inspiring, and produces pleasure, bliss, and ecstasy. If God made the path to eternal life difficult, He/She would be a sadist Who has doomed us to eternal misery. The only thing difficult about it is giving up your addiction to misery. Changing gives us the immense satisfaction of accomplishment.

Simple spiritual purification practices like bathing twice per day, conscious energy breathing, fire purification, an exercise system, a conscious diet, loving relationships, and mastering a mantra are the basic common denominators of the lifestyle of all the immortal masters I have met. These spiritual practices with earth, air, water, and fire can clean the mind faster than the mind can clean the mind. They are healing magic. In the process of mastering these, we must develop a balance between solitude and service.

I've written many books about physical immortality and the practical principles of conquering death and I recommend that you read them all and use my tapes repetitively if you are interested in personal mastery. But every year I try to put this simple truth into one page, in a clearer and easier way for people to understand.

Anyone can read or have read to them one page and have their mind expanded to receive the joy that this great idea brings. It unshackles your creativity and releases enormous reserves of energy and intelligence.

Is physical immortality realistic? Yes, if we honor the following. The three basic secrets to physical immortality are:

1. to stay tuned into God – Infinite Energy, our Source – all the time. Have pure thoughts and Life.

2. to heal the death urge. Healing the death urge can take us through the most ugly emotions of suicidal and homicidal thoughts – we have to survive the illusions in our own mind and go for wisdom and bliss.

3. to keep our energy body clean and balanced with the simple and pleasurable spiritual purification practices with mind, earth, air, water, fire, and love.

When we eat food we have to clean the dishes, etc. When our home gets dirty, we have to clean it. We also have to wash our clothes. When our energy body (also called emotional body) gets dirty through absorbing emotional energy pollution as we participate with people or in our self-healing process, we have to clean ourselves emotionally and spiritually. It is a daily process. Spiritual cleanliness is Energy and Peace.

If we stay ahead of the pollution – cleansing process, we become more alive every day. If we lose the spiritual purification game, we become more dead every day. Victory or victim?

One of the indicators is the guru belly phenomena. The solar plexus chakra is the social chakra and emotional energy pollution can be collected physically in the form of fat around the navel – it is sometimes called psychic fat.

Another indicator is stiffness. An over loaded body gets stiffer and stiffer every day and every year until we become a stiff – and are buried. When we absorb other people's death urge, we can get depressed, feel suicidal, become prone to anger, be grouchy, or have violent dreams. Victim consciousness in all its forms is a sign of death urge.

I'll finish this page with an idea which is a million times greater than physical immortality, and is the source of personal mastery or misery and death. It is this: 'Energy becomes what it thinks about'. Your personal energy is the Eternal Spirit – God Within – your natural divinity.

This Infinite Eternal Energy is helpless and powerless without thought and yet it is the power of thought. Your unlimited potential is only potential until it has been activated and directed by your thoughts. Energy is directed by thought.

Infinite Power directed by thoughts of weakness can produce infinite weakness. Infinite power directed by wholesome and healthy thoughts produce infinite wholesomeness, health, and safety – beyond safety – peace and pleasure. Thoughts of death produce death. Thoughts of Eternal Life produce physical immortality and body mastery. The body is Energy materialized by thought; not passive thinking, but active thinking; thought in motion. Your physical body and emotional body have been built up by millions of thoughts in action. To be a master, you now have to catch the thoughts and change them with the kind of actions that produce the results you like. We are all scientists and our body is the laboratory. Various nutrients have been created by thinking beings to produce certain effects in the body. Some of these cause and effect relationships are simple and some are quite complex. And simple fasting is the direct route to the purity of Infinite Energy. However, it is also possible to starve to death for spiritual purposes. We have to learn balance and common sense. More people die from overeating today than from starvation.

Repentance is fun! Changing our minds is the great, eternal adventure of all intelligent divine beings.

Playing in your Spirit Energy, your Divine Mind, and your Infinitely Beautiful Body is what Eternal Life is all about.

Have fun!

Patents for Immortality

JP2013240722
ASTRAL PROJECTION APPLIED IMMORTALITY DEVICE 6 AS MIND TRANSFER (MIND UPLOADING)

Inventor:KAJISA ISAO
[0001]

The present invention relates to a dedicated human humanoid cyborg robot with the spirit of the transfer-body application immortality device (spirit upload).
[0002]

Conventional, not the technology transfer spirit (spirit upload), out-of-body application immortality device technology had but spirit transfer of its application on the (spirit upload) and special remembrance in motion, humanoid humanoid cyborg robot that becomes the power source It was not.
[0003]

"Nihon Keizai Shimbun electronic edition" August 5, 2013, "the Nihon Keizai Shimbun electronic edition" January 2, 2013 "separate Nikkei Science perceived phantom" October 15, 2010, 114 pp -117 The Lancet 2001 year December 15, pp. 2039 2045 "Nature" September 19, 2002, 270 pages from 269 pages "free encyclopedia Wikipedia" mind uploading
[0004]

Conventional, extracorporeal withdrawal application technology related to immortality device had but spirit transfer of its application (spirit upload) and dedicated praying to the movement, and to realize it by the latest technology because there was no human humanoid cyborg robot that becomes the power source.
[0005]

The infrared sensing to humanoid humanoid cyborg robot to move in-body and consciousness energy (spirit) the spirit and transfer (spirit upload) praying with ketamine taking Hemishinku technology or right brain right corner gyrus electrode stimulation and right brain auditory cortex near the electrode stimulation and anesthetic can all flesh human similar behavior in that you have loaded fixed that vessel, it is assumed that even as a power source for the human humanoid cyborg robot.
[0006]

Surely enables action by the same storage consciousness and when of the-body can pray immortality of the body in human humanoid cyborg robot that moves and body with ketamine dose of anesthetic, that the spirit transfer (spirit upload) and a power source It uses a heat current of consciousness energy (spirit).
[0007]

Below, it described in the series logically sentence when the embodiment of the present invention. First, it is possible to reliably-body with ketamine taking Hemishinku technology or right brain right corner gyrus electrode stimulation or right brain auditory cortex near the electrode stimulation or anesthetic, out consciousness energy (spirit) to the outside of the body, around the senility and the sick and the elderly, In infrared sensor because the above-body was conscious energy (spirit) whole body moves in the electrical signals of the brain enters Prepare a humanoid humanoid cyborg robot, consciousness energy to the human humanoid cyborg robot (spirit) can be sensed by the infrared the humanoid by inducing the humanoid cyborg robot fixed (spirit transfer, spirit upload) and, the conscious energy (spirit) and power also becomes a source of power humanoid humanoid cyborg robot, from the portion corresponding to the brain of the consciousness energy all even after it moved from the human body to the human humanoid cyborg robot that have in mind the human body similar to this consciousness energy in an electric signal entering the humanoid humanoid cyborg robot of the brain (mental) and can do the same thing as human beings, power source it becomes a power supply, in-body dedicated human humanoid cyborg robot, mind uploading with the feature as more-body application immortality device as a (mental upload) 6.
[0008]

It is carried out as described above in the form and non-patent literature.
[0009]

Enables the realization of immortality by-body dedicated human humanoid cyborg robot as a spirit transfer (spirit upload), the availability of the industry in an aging society is I is understood to be high.

JP2013233468
ASTRAL PROJECTION-APPLIED IMMORTALITY DEVICE AS MEDICAL DEVICE

Inventor:KAJISA ISAO

[0001]

The present invention relates to a dedicated human humanoid cyborg robot-body application immortality device.
[0002]

Traditionally, there were technology related to ketamine dose-body application immortality preparation of human iPS rejuvenation body system drugs move in remembrance of its dedicated, there was no human humanoid cyborg robot that becomes the power source.
[0003]

"Nihon Keizai Shimbun electronic edition" August 5, 2013, "the Nihon Keizai Shimbun electronic edition" January 2, 2013 "separate Nikkei Science perceived phantom" October 15, 2010, 114 pp -117 The Lancet 2001 year December 15, pp. 2045 from page 2039 "Nature" September 19, 2002, 270 pages from 269 pages
[0004]

In the past, technology was related to ketamine dose-body application immortality preparation of human iPS rejuvenation body system drugs move in remembrance of the only, to be implemented by state-of-the-art technology because there was no human humanoid cyborg robot that becomes the power source.
[0005]

body human same by Hemishinku technology or right brain right corner gyrus to electrode stimulation and was placed in the right brain auditory cortex near the electrode stimulation and infrared sensor to humanoid humanoid cyborg robot to move in remembrance consciousness energy that was out of body with ketamine dose of anesthetic fixed behavior can be any, it is assumed that also a power source of humanoid humanoid cyborg robots.
[0006]

Surely enables action by the same storage consciousness and when of the-body can pray immortality of the body in human humanoid cyborg robot that moves and body with ketamine dose of anesthetic, to use the heat current of the consciousness energy to a power source .
[0007]

Below, it described in the series logically sentence when the embodiment of the present invention. First, Hemishinku technology or can be reliably-body with ketamine dose of right brain right corner gyrus electrode stimulation or right brain auditory cortex near the electrode stimulation or anesthetic, issued a consciousness energy to the outside of the body, around the senility and the sick and the elderly, said of body a humanoid humanoid cyborg robot is prepared consciousness energy that was systemic is in electrical signals of the brain move to enter, consciousness energy to the human humanoid cyborg robot was induced in the human humanoid cyborg robot with infrared sensor because it can sense the infrared fixed Te, the conscious energy and power also becomes a source of power humanoid humanoid cyborg robot, the human body similar to this consciousness energy in electrical signals of the brain went into the humanoid humanoid cyborg robot from the portion corresponding to the brain of the consciousness energy all even after he moved from the human body to the human humanoid cyborg robot of have in mind that it can do the same thing as human beings, become the power source of power, medical equipment with in-body dedicated human humanoid cyborg robot, the as features more -body application immortality device 5 as.

[0008]

It is carried out as described above in the form and non-patent literature.
[0009]

It enables the realization of immortality by-body dedicated human humanoid cyborg robot as medical equipment, industrial applicability in the aging society I is understood to be high.

AGED ELDERLY PERSON HUMAN iPS 6 FACTOR COATING INITIALIZATION TELOMERE REJUVENATION
UTILIZING ELDERLY PERSON'S BRAIN PHOTOELECTRODE STIMULATION WHOLE MEMORY RECALL ORAL IMMORTALITY DRUG

Inventor: KAJISA ISAO

[0001]
The present invention relates mainly elderly old man case in improvement of human iPS6 factor cell initialization old man brain total storage resurrection use oral immortality drugs 3.

[0002]
Conventional, technical elderly for the elderly on human iPS cell initialization 6 factor use oral immortality drugs was small.

[0003]
"Mainichi" October 11, 2012, page 1.
"Mainichi" December 4, 2012, page 12.
"Nature online version of" March 2012 22 date, "Yomiuri Shimbun" November 5, 2011

[0004]
Conventional, technical elderly for the elderly on human iPS cell initialization 6 factor use oral immortality drugs thereby improved achieved through state-of-the-art technology because it was less.

[0005]
The elderly old man human iPS cell initialization 6 factor to perform the resurrection coating or basket put the elderly brain total storage put into plasmid in the hippocampus and cerebral light electrode stimulation.

[0006]
It kept the body of immortality.

[0007]
The following, it will be described in the series in the sentence when the embodiment of the present invention.
Elderly elderly person iPS6 factor a is initialized Oct3 / 4 needed to, Sox2, Klf4, L-Myc, Lin28, prepared Nanog, coating these six factors as taking into plasmid not destroyed by stomach acid and heat and or, is placed in a "cage" of a protein, conventionally, although the plasmid was placed in the blood, which was a simplification in that drinking from the mouth by the oral expression, the whole cells in elderly nursing Thus It is initialized, telomeres also rejuvenated as it becomes oral immortality drug return to its original length but in the initialization of the brain cell memory also revived either, the hippocampus and cerebral in the brain light stimulus or the electrode stimulation

to all storage revived old man brain also becomes younger, more oral immortality drugs 6 resurrection elderly elderly person iPS6 factor coating initialization telomere rejuvenation use old man brain light electrode stimulation total storage with features such as.
[0008]

It is carried out as described above in the form and non-patent literature.
[0009]

The elderly elderly person iPS6 factor coating initialization telomere rejuvenation use old man brain light electrode stimulation total storage resurrection oral immortality drugs 6 in the advance is aging made a big progress in improved techniques of human iPS cell initialization 3 gene use oral immortality drugs the industrial applicability of the demand of this medicine is understood to be high.

ORAL DRUG FOR ETERNAL YOUTH AND IMMORTALITY PREVENTING AGING INFLAMMATION BASED ON TELOMERE REJUVENATION CAUSED BY REDIFFERENTIATED T CELL OF HUMAN IPS

[0001]
The present invention relates to a T cell re-differentiation telomere rejuvenation aging inflammation stop oral immortality drug 4 of human iPS.

[0002]
Traditionally, technology related to human iPS cell initialization use oral immortality drugs was small.

[0003]
"Mainichi" January 4, 2013, page 3.
"1000 life" July 25, 2012, Hayakawa Jonathan Weiner.
"Aging could heal," March 20, 2013, Shueisha Shinsho, Makoto Goto.

[0004]
Traditionally, technology related to human iPS cell initialization use oral immortality drugs can be improved achieved through state-of-the-art technology because it was less.

[0005]
After T-cell initialization of human iPS re-differentiated to lengthen the telomere, a coating or basket put oral eliminate the garbage of aging inflammation stop and cells.

[0006]
It kept the body of immortality.

[0007]
The following, it will be described in the series in the sentence when the embodiment of the present invention.
Re-differentiation of T cells of the human iPS it shows signs of long stretched rejuvenation telomeres.
Aging is to eliminate the waste of the cells of the seven causes of cure outdated inflammation stop that aging in the re-differentiation T cells because the inflammation that in the garbage of somatic cell aging in this re-differentiation T cells.
The iPS cells are coated with a rejuvenation re-differentiation T cells so that it is not destroyed by stomach acid and heat so that growth, or is placed in a "basket" of the protein.
Conventionally, although the regenerated T cells were placed in the cells, which was a simplified that drinking from the mouth by the oral type.
In this way, the whole cells are initialized to eliminate waste of cells, most of the blood is to achieve immortality by feeding the regenerated T cells are in the T-cells into the somatic cells from the blood.
Rejuvenation T cell re-differentiation telomere of human iPS with features such as more aging inflammation stop oral immortality drugs 4.

[0008]
It is performed as in non-patent document mentioned above.

[0009]
Human iPS of T cell regeneration telomere rejuvenation aging inflammation stop oral immortality drug 4 on the industry demand for this drug in the advance is aging made a big progress in improved techniques of human iPS cell initialization 3 gene use oral immortality drugs The availability of it is understood to be high.

ULTIMATE CYBER SECURITY SWITCH, 9/11-EQUIVALENT EVENT-PROOF SWITCH, AND OTHERS

Inventor: WU WEIMIN [CA]

Ever since the inception of internet, hackers from different countries have been successfully defeating many governments and more than 70 corporations around the world in cyber warfare: as, the USA, Canada, Taiwan, South Korea, Japan, and many others according to the news broadcasted by CNN, CBC, etc. All their helpless and unstoppable defeats only root in their lack of one of my inventions titled: Ultimate Cyber Security Switch. Only this invention is qualified to defeat all individual and government-sponsored hackers by preventing and stopping them from hacking into any cyberspace that is protected by this invention. Therefore, this invention can save all these losing countries billions if not trillions of US dollars each and every year of losses from intellectual properties, military intelligence, economic intelligence, financial information, etc. And since many ages ago, people have been mining gold with wash plant, panning, etc hoping and fantasizing becoming rich. But existing sluice and riffle systems are simply too inefficient with a lot of gold loss through the sluice and riffle systems. Hence, I have invented a series of revolutionary gold mining equipments and processes to expedite gold production yet minimize loss. Moreover, the Law of No Largest, or Smallest, or Any Other Absolute Limit established by me states that throughout the universe nothing can be the smallest or the largest. There is never either upper or lower physical limit to anything throughout the universe. There is perpetually something smaller than the smallest particle that can ever be found; there likewise is perpetual something larger than the largest expanse that can ever be found. Therefore, Higgs Boson (or God particle) sought in the Hadron Collider in Switzerland, or any other so-called particle can never ever be the smallest particle because there perpetually is something even smaller than the smallest particle that can ever be found according to this Law. The Law of Time Delusion established by me states that in fact time is but a delusion because there is no reality in any time. It is only because time is but a delusion that other animals live in perpetual non relativity with no concept or sense of time. And it is also only because time is but a delusion that the selfsame number of hours or any other periods of time to the selfsame person are felt and perceived completely different whenever and if he or she falls asleep and whenever and if he or she fells anxious. And it is also only because time is but a delusion different people can agree on an arbitrarily set or assigned time. Albert Einstein and a plethora of other scientists are absolutely wrong about the nature of time. Because time is but a delusion, any attempt to seek any form of time travel is foolishness, failure, and waste of life in the making. Time travel, such as Einstein's Rosen Bridge, wormhole, Higgs singlet, time travel portal, or any other form of time manipulation is absolutely impossible though people can always so fantasize, just as a lot of people would always waste lives fantasizing immortality though it is impossible. It is likely foolish for anyone to believe that Nazi Bell could somehow manipulate time by spinning red mercury, etc because time is but a delusion. The Law of Inevitable Randomness establish by me states that only by involving randomness in one way or another rather than regulated or calibrated actions and/or processes any ultimate state can be attained. For example, in order to polish any mirror to its ultimate resolution possible, random polishing process must be implemented. To expand this law to other area, according this law Albert Einstein's Spooking Communication Theory is also a fraud because it is but random coincidence by which two distant objects sometimes exhibit entanglements, same behaviors, etc, not any dictating law or regularity. But Einstein had mistaken the random coincidence between two distance objects for the act of law or regularity. Furthermore, ultimately on the one hand anything must encompass an element of randomness; on the other hand, only randomness can cause anything or state to achieve the culmination of that thing, much as only hand-polished or random-action-polished lens can attain the ultimate precision of their size. And then the Law of Uniqueness likewise established by me states that, at the level tending to either infinite large or small and no matter how adamantly a person desires otherwise, everything throughout the universe must be and can only be unique; therefore, there cannot be another planet or any other heavenly body like the Earth which sustains life. Therefore, there has never been, and never is, and will never be any life anywhere throughout the entire universe. The Law of Uncertainty also established by me states that there perpetually exists an element of uncertainty in all human affairs (especially whenever and if great interest becomes at stake), any phenomenon, and any existence. For example, albeit Popes have always done their best to conceal their secrets from their donors for decades, these laws had recently dictated a unique butler of one of the Popes to have just divulged only few unimportant Vatican secrets against all their ardent desires to hide the truth from the donors, supporters, and followers. Ever since the split second on such a birthday when the human species had emerged onto Earth, people have killed and harmed one another to establish empires, wealth, power, predominance, social strata, fame, successes, etc for selfish aggrandizement; but none of such lifetime have been wisely spent because all conquerors and/or winners have died, much as all ordinary people and losers do. Therefore, all their cunning, brutal, and hell-for-leather rampages, campaigns, maneuvers, intrigues, duplicities, chicaneries, deceptions, etc eventually have been but foolish dissipations of lifespan in vain at the pursuing for any thing but that which can last. And furthermore, billions of innocent people have already been defrauded, deceived, brainwashed, victimized, and/or inflicted in respect to the authentic and genuine truth and true reality of universe containing life, mind, and other existences. Even as recent as December 2012, delusional faiths in the country of India of multiple dysfunctional faiths had driven many Indian men into gang-raping and/or murdering women in their country in the most uncivilized manner. All people's all uncivilized conducts and inner sufferings can only ultimately root in delusional faiths because only their deceptive faiths, beliefs, and hence mindsets drive them into their behaviors and then foolish ways of life. Their faiths are delusional and hence they are dysfunctional because the ultimate faith always functions. All conventional faiths/belief systems have always been predicated on the diffusions of lies, frauds, deceits, misinformation, deceptions, and brainwashing that are devised to batten on, defraud, and abuse their parishioners, other followers, and their innocent children. Had these inventions not come to fruition, and so long as the human race can still endure the living conditions on this planet, people will continue enduring countless faith predators that will continue defrauding, brainwashing, victimizing billions of faith victims, as since the emergence of humankind on this planet they have always battened on their faith victims throughout the world and even have sexually exploited/molested the innocent children of their faith victims in none other than the places of worship. The places of worship are also sometimes used as their bases for other crime: as, some faith predators have actually been charged for selling child pornography, etc in none other than the places of worship. Therefore, these inventions are of unprecedented and historic significance, practicality, and value since they qualify to prevent future billions of innocent human beings from continuously being defrauded, brainwashed, victimized, and/or harmed by faith predators with their delusional faiths, and they revolutionize and upgrade the vision, sphere, and capability of the humanity. My qualification cannot manifest it clearer to me that the effective ways and strategies to prevent or reduce the sufferings of innocent lives from continuing being misled, brainwashed, victimized, and/or harmed are to live the correct faiththe correct belief system. As a member of true integrity and righteousness of the human species and we are stumbling across one another on the universal yet against-our-will-journey of aging towards inevitable death instincts, I am behooved and honor-bound to provide the humankind with these inventions to upgrade human knowledge so as to dispel the worldwide spiritual plague and precipices of delusional faiths, misled beliefs, misled perceptions, misled preconceptions, misled information, misled knowledge, misled science, etc that have been deluding, victimizing, and/or afflicting the humanity since its emergency tens of thousands of years ago. Only in so doing, said deceits, frauds, whoppers, delusions, etc against humankind can be so lifted and dispelled that mankind will no longer suffer in ignorance, delusion, deceit, pseudo-science, etc. Only the correct knowledge, insight, and faith about mind, life, and universe can be qualified, on all terms for anyone, to harness and/or manifestto the ultimate maximathe human potential of the mind and/or the body; otherwise, all talents, knowledge, knowing, faculties, etc are perpetually limited and confined within the spheres of apparent reality without ever becoming qualified to be expanded to, upgraded into, or evolved into true reality transcending apparent reality. Only by living true reality guided by the ultimate faith (the truly correct and hence functioning faith/belief system) anyone can become qualified for life to enjoy mind freedom including emotional freedom, etc and omniscience... &c &c

---

CN103127604
Anti-aging method through inorganic substance content reduction

Inventor: WEN DONG

The invention provides a method for achieving immortality and even achieving rejuvenescence by humans. The method is mainly composed of a human aging theory and a part about how to preventing human aging. The method is characterized in that when a human body sweats by a great amount, edible rice vinegar is sprayed all over the human body to enable pores all over the body to absorb the rice vinegar into the human body. After entering the human body, the rice vinegar can prevent most inorganic salts in the human body from generating precipitates and even dissolve inorganic salts which are already precipitated and include calcium oxalate, calcium phosphate, calcium carbonate and the like in the body. The specific weight of the inorganic salts in the human body in the human body is reduced through dissolving of parts of the inorganic salts in the human body and exhausting the parts of the inorganic salts out of the human body so as to prevent aging. The method of spraying rice vinegar on the human body has the advantages of being small in toxic and side effects of rice vinegar, low in cost, favorable for popularization, easy to operate, free of training, strong in controllability, and capable of increasing and decreasing the spraying times and the concentration of the rice vinegar for adjustment according to needs.

[0001]

Biological theory of aging and how to prevent biological aging process of the present invention patent relates.

[0002]
In the scientific community there are two theories of biological aging: one for congenital doctrine, they think the gene is a key factor in the decision to biological aging, so they stepped up to crack the genetic code.
Another theory that biological aging postnatal environment is a key factor in the decision.
I support the latter theory, following talk about my reasons.

[0003]
Many biological phenomena acquired environmental biological explanation is the main factor in determining the biological aging, but with the gene theory is difficult to make sense.
Illustration: ? Scientists have done experiments with rats, scientists fed mice by strictly controlling the amount of food, can significantly improve the lives of mice; ? millennium water lily seeds can still grow after germination millennium; ? the nature of the worker bees and the queen are the same Eggs females, almost similar gene, and because they eat different food, their life can vary several times as much, eat royal jelly queen bee, worker bees eat honey; ? biosphere has immortality phenomena, such as scientists are Research by the division of reproductive sector insects and other genes in the same situation, you can go on unlimited split.

[0004]
By summarizing many biological phenomena, we find that the metabolism of biological aging is caused by the main reason, does not participate in the metabolism of the organism does not occur aging, such as water lily seeds did not sprout before aging.
We believe that the organisms absorb nutrients from the outside world during the same time inhale a possible biological aging substance, it is an increase in the accumulation of such substances, resulting in a biological aging and even death.
Death from natural biological aging and biological aging should not be reversed.
I infer that this substance constitutes organism must matter, and according to the organism childhood ? adult ? elderly, this substance is gradually increased.
We then constitute organisms substances into three categories: 1, organics; 2, water; 3, inorganics, in line with the above conditions only inorganic.
Anatomy of an organism we can prove that all organisms inorganic content is based on biological, childhood ? adult ? elderly gradually increased, and this phenomenon in nature is impossible to reverse.

[0005]
Here we focus on to explain why the increase in the accumulation of inorganic substances, can cause biological aging and even death.
Both soluble and insoluble inorganic fraction non soluble salts in the body is difficult to gradually increase, can gradually accumulate in the body increase is mainly insoluble inorganic salts.
And yet one inorganic salt from a soluble to an insoluble.
We can no longer participate in life activities, and it is on the rise in vivo, inevitably resulting in a decline of vitality.
Suppose the same total body weight, increased body salts, the most straightforward is caused by the body of water and organic content share declined, and the vitality of life depends on the organic matter, organic matter decline in the proportion, vitality will decline.

[0006]
Here I vessels in the human body as an example Details: Patrons are inseparable from human cells and blood vessels, if the intake of food from outside the gradual deposition of inorganic salts in the body vessel wall, will inevitably result in smaller diameter vessels, resulting in the ability to pump blood vessels decreases, the supply of such cells that can be obtained will decrease, caused by aging

cells due to lack of support.
And then to human bones as an example, the following figure taken from biology textbooks

[0008]
We know that the bone marrow is where blood.
Bone marrow is the organic matter from the table, we can see very intuitive, as people age, bone mineral content increased, the proportion of organic matter decline, the body's hematopoietic function decline, hematopoietic capacity decreased, and causing cell received support decline, so that cell senescence.

[0009]
Based on the above reasoning, I believe that biological life depends on its in vivo accumulation of inorganic increased speed, long slow accumulation of biological life, rapid accumulation of short biological life.

[0010]
As the above theory is correct, we inorganic body by blocking an increase in vivo or in people insoluble salts into soluble salts from the body, reducing the proportion of body salts, humans will be possible to achieve longevity not old, even rejuvenated.
Here is the experiment conducted to prove that I assumed that I was 20 years old body mineral content as a percentage ratio of the weight value, and now I am 35 years old, if the proportion of inorganic let my body fall to 20-year-old value, then I will be able to reproduce the 20-year-old face.

[0011]
In order to make my body proportion of inorganic fall, it began in 2006 a large number of oral consumption of vinegar, hydrochloric acid, experiments carried out for almost a year, due to the mouth, stomach, liver, kidney and are subject to different degrees of damage, teeth can hardly bite hard, experiment was interrupted, after years of conditioning.
I also began at the end of this year, another experiment in vivo method of inorganic salts dissolved.
The in vitro method into the liquid, that is, after the body a lot of sweat, edible vinegar sprayed on the skin surface, absorbed through the skin into the body, several times a day.
Carried out for nearly four months, the experimental results began to appear, performance 1, the original bald hair out, hair began to grow new small, 2-3 cm long now; 2, skin wrinkles begin to disappear, the skin begins to become more tender.
3, has white hair began to darken; 4, the bones become more elastic, the whole body feels lighter, more power becomes abundant.

US2013035375
Gene re-cycling

Inventor: MATHEW ZACHARIAH

Through ecological re-cycling, plants take up the nutrients from the cadavers. But it is not understood whether the plant roots can take the nutrients and the genes of the dead plants and cadavers, to develop into a transgenic plants. Biotechnology has successfully developed transgenic plants and animals. Recently, gene sequencing studies, have shown that animals carry foreign genes making them as natural transgenic animals. Reason for the presence of transgenes not investigated. Further studies will enable us to learn more about the existence of transgenic flora and fauna and the role of gene re-cyling. Corroborating the Nature's hidden biological phenomena, like ethnicity, cyclic occurrence of diseases, re-appearance of extinct animals, Biblical citations etc., with modern literature on transgenic plants/animals, human genomic studies. gene sequencing, etc. it is hypothesized that genes of flora and fauna are recycled from generation to generation through immortal DNA. It will change the present concept of organism's mortality to immortality.

[0001] Current literature on the cutting edge Biotechnology experimental findings, genetic engineering, gene sequencing and gene resequencing studies have enabled to hypothesize, the theory of “Gene re-cycling”, that genes of every flora and fauna are recycled from generation to generation through the transgenic plants, humans, animals, birds or fishes.

[0002] Gene re-cycling theory will reveal the scientific truth behind the natural biological phenomena occurring in our planet.

[0003] As per the natural phenomenon occurring and the modern literature cited below, plant's roots can attract the genes from the humus of other organisms in the soil/water which will then become an integral part of the plant chromosome.

[0004] Such foreign genes from other species of organisms, after integrating it into the plant chromosome, will remain inactive and enter into a latent period. Genes, after entering into a homologous host and under appropriate environmental conditions will become active again and multiply with the gene expression of the original homologous host.

SUMMARY

[0005] This is a new theory invented/hypothesized. It has great utility for the following purposes:
1. Knowledge of disease outbreak/infection caused by the genes of pathogenic organisms transported from soil and water via transgenic plants/fishes to humans and animals, can help to take appropriate disease control measures,
2. Revealing the root cause of biosphere ethnicity due to genes in the food from Transgenic plants and animals,
3. Understanding the effect of expression of genes in the food on physiological and genetic changes in humans, animals and plants.

Revised Experimental Proof

Introduction:

[0009] In the earlier Provisional Application dated Sep. 30, 2008, an experiment was planned to conduct the Gene sequencing and re-sequencing of human genome to prove the Gene Recycling and development of ethnicity. On my preliminary enquiry with gene sequencing scientists, it was found out that human genome has more than 1 million base pairs and the cost of sequencing and re-sequencing of human genome will be very high, since sequencing each base pair will be around ¢5 per base pair.

[0010] Hence it was decided to plan the experiment of gene re-cycling, with beef cattle (meat) having less number of genome base pair (roughly 22,000 genes). Sequencing of cow's Genome has been studied and is available in the Genome bank.

[0011] Current literature: In the AARP bulletin today (http://bulletin_aarp.org/your/health/policy/articles/scientists _unravel_genome_of_the_cow.ht.8/82009 it was reported that “Of cow's 22,000 genes versions of at least 14,000 have counterparts in other mammals. Cows appear to have 1000 genes that they share with dogs and rodents (Brown, and Lewin 2009)”. It shows that 1000 latent genes of heterologus species (dogs and rodents) that are not found in people, might have entered the cow's genome through gene recycling, developing the animal into a transgenic cow. This transgenic cow, hidden in her roughly 22000 genes are hints of how natural selection/gene re-cycling, sculpted a bovine, with full gene expression over the past 60 million years (Brown, D and Lewin, H. A. 2009). It shows that

1000 latent genes of heterologus species (dogs and rodents) that are not found in people, might have entered the cow's genome through gene re-cycling, developing the animal into a transgenic cow. This transgenic cow, hidden in her roughly 22000 genes are hints of how natural selection/gene re-cycling, sculpted a bovine, with full gene expression over the past 60 million years (Brown and Lewin, 2009)". This scientific report indicate that natural biological Gene re-cycling results in the development of transgenic organism, creating new species of a unicellular/multicellular organism (extinct animals and birds) through Gene re-cycling take place with long periods of time, depending upon the biology of the organism.

[0012] The above scientific literature fully proves/support the theory of Gene Re-cycling, as transgenic animals are being developed naturally in the development of new life on Earth. When the genes, recycle through inter species and intra species, it makes the genes immortal with or without mutation. As time goes many such articles may be published proving gene re-cycling is not a Hypothesis, but a proven naturally existing scientific truth. This made me to submit a Non-provisional Patent Application.

[0013] Meanwhile I have also planned an experiment, which may not be necessary as per the scientific proof given in the paragraph [0008 and 0009] given above to produce transgenic cereal plant by planting the cereal seeds in soil buried with beef meat (putrefied). After conducting the squencing and re-sequencing studies of the beef cattle genes and that of cereals, the transgenic genotype of the cereal will be decided.

[0014] After confirming the transgenic nature of the cereal it will be fed to the mice/rabbits and observe those experimental animal for the transgenes from the beef cattle. The result will be published in scientific journal/scientific conference.

[0015] In the light of the above a Non-Provisional Application on "Gene re-cycling" as given below, has been submitted as a continuation of Utility Provisional application No. 61/194,637 Dt. Sep. 30, 2008 for Patent registration.

[0016] Plants take up the nutrients from the dead and putrefied flora (humus) & fauna, recycle it for the nutrition and growth of humans, plants and animals, and thus maintain ecological re-cycling system. Similarly the herbivores and carnivores animals also play their own role in the ecological recycling process. However more scientific data is required to know, whether the plants can take not only the nutrients but also the genes/viruses/bacteria from the infected materials, dead animals, humans, birds or plants in the soil & water and recycle those genes, generation after generation making the biosphere as immortal. Hence it is hypothesized that genes of every flora and fauna are recycled from generation to generation through the plants, humans, animals, birds and fishes (living in land, sky and water).

[0017] When the "Gene Recycling" hypothesis is proved the concept of mortality of living beings will be changed to immortality. This is a postmodern century of interrogation. "Gene Recycling" hypothesis can provide full or partial answer for many of the Mother nature's biological phenomenon we now see in the world.

[0018] Based on the modern scientific literature and technology, the theory of "Gene Recycling", can provide a strong support to the natural unknown biological phenomena occurring in our planet. It is in the hidden plan of the Creator for making the biosphere/life on this planet as immortal. As per the natural phenomenon occurring and the modern literature cited below, plant's roots can attract the genes from the humus of other organisms in the soil/water which will then become an integral part of the plant chromosome. Such foreign genes from other species of organisms, after integrating it into the plant chromosome will remain inactive and enter into a latent period. Genes, after entering into a homologous host or under appropriate environmental conditions will become active again and multiply with the gene expression of the original host. The scientific literature given below provide s a strong support to the “Gene Recycling” hypothesis.

Natural Biological Phenomena:

[0000]
1. Prevalence of Ethnic Population and Evolutionary Conservatism.

[0020] All organisms on Earth appear to be unrelated in the evolutionary process of different species of plants, birds, animals, mammals and humans. But a detailed study of the molecular biology of cells, has shown that basic molecular structure of all living organisms are conserved to a great extent and all have the same chemical structure such as amino acids, sugars, fatty acids and nucleotides. Besides the above, other resembling factors are that the genetic information of all multi cellular organisms, stored in the genome, is carried by DNA and is transported, from generation to generations. The hereditary information is stored in all the cells in the DNA as chemical code, arranged in linear fashion (Koonin, 2002).

[0021] We can also notice the family resemblances among genes coding for proteins. Genes and portions of genes get duplicated to develop into new diverse genes through mutation of the parent genes. Usually one cell expresses only a fraction of its genes. Changes in the environment due to signals from other cells can influence the pattern of genes they express. The gene expression by different sets of genes produces different types of cells in a multicellular organism. Thus a small group of genes may multiply to develop into higher plant or animal species with large number of genes. A broad phylogenic picture provides a rough idea of the relation ship between the species on our planet Earth (Li, W-H and Graur, 1991).

1. (a) “Gene Recycling” Hypothesis Claim:

[0023] If the roots of the plants are taking organic and Inorganic nutrients along with the genes from the human and animal cadavers, then the plant and its parts or fruits will also contain these human, animal genes, which will remain as tent genes. The plant/its parts or fruits containing such foreign (human/animal) latent genes, when consumed by other people in the locality or town, the genes may enter their gastro intestinal system and reproductive system (gonads). It may then remain in the system as latent genes. These latent foreign genes which have entered into the gonads may pass it on to their progeny and become active and provide gene expression (dominant genes) in the next generation of people in the locality/town. This will result in ethnicity (common characters related to place of origin, culture, speech, food habits etc.) in those local people.

1. (b) Supporting literature:
1. (b) 1. Transgenic plants:

[0026] Genetic engineering studies have revealed that a mutant gene can be inserted into the chromosome of a plant cell and it becomes a part of the plant genome. In the laboratory experiment it has been shown that, when the tobacco leaf discs incubated in a selection media with genetically engineered Agrobacteria, the injured cells at the edge of the plant leaf disc, released substances that attract the Agrobacteria which carry a recombinant plasmid with a selectable marker and desired transgene, inject its bacterial DNA into the plant cells. The plant cells which take up the appropriate bacterial DNA, survive and proliferate to express the selectable marker gene, and develop into a callus. When these calluses are placed in special medium, it will induce the production of shoots. These then develop into adult plants carrying transgenes (Davey et al., 1989 & Walden and Schell, 1990).
1. (b) 1.1. Transgenic Plant Experiment Supports the Hypothesis:

[0028] Similar to the experiment stated above if an injured cell from the plant leaf is attracting the DNA from the bacteria; as per the hypothesis, under natural environmental conditions, the injured cells of plant roots can also attract/absorb/take up the gene(s) along with the nutrients from the dead and putrefying flora (humus) and fauna in the soil/water. When such a foreign gene from other species is recognized by a plant cell, it will efficiently transfer a DNA strand of human/animal/bacterial/viral gene to the plant cell. It then becomes the part of plant chromosome, survive to grow into a transgenic plant carrying such a foreign gene.

1 (b) 1. 2. Possibility 1:

[0030] The transgenic plants (or its product) carrying foreign gene when consumed by species homologous to the gene, it can develop to express the phenotypic and genotypic characters of the gene. In other cases it may remain as latent gene and express it only when it enters into a host homologous to the gene.

1. (b) 1. 3. Possibility 2:

[0032] The transgenic plants (or its product) carrying foreign gene when consumed by species heterologous to the gene, it may remain as a latent gene and will pass it on to its progeny and continue to remain as latent gene in the progeny.

1. (b) 2. Transgenic animals:

[0034] In the case of mouse, foreign DNA can be randomly integrated into the genome. When fragments of DNA are introduced into cells, they are rapidly joined end to end by intra cellular enzymes and form long tandem arrays. These are then randomly integrated into a chromosome. When original gene(s) of an animal, is thus altered permanently, such an animal is known as transgenic animal. The genes which are responsible for altering are called transgenes (Boyd and Samid, 1993 & Palmiter and Brinster, 1986).

1. (b) 3. Role of Gene Regulatory Proteins:

[0036] Genome (whole set of genetic information belonging to a cell/organism carried by DNA) in its DNA sequenquence carries the information to express many thousands of different proteins and RNA molecules. Usually cells express only a fraction of its genes. The gene expression by different sets of genes produces different types of cells in a multicellular organism.

[0037] Changes in the environment such as signals from other cells can influence the pattern of genes they express. Even though the expression of a gene is generally regulated, the initiation of RNA transcription will be an important control point for most genes. The transcription of the gene in the DNA is controlled by the regulatory region at which it starts. These regulatory regions function like tiny microprocessors. Thus these regions act like switches by responding to the various signals, which they interpret and integrate the neighboring gene to switch on or off. Bacterial Genetic study conducted in 1950 gave the first evidence on the existence of “gene regulatory proteins”. These gene regulatory proteins, turns specific sets of genes on or off, the production of proteins. These are called “repressors” as they shut off the production of proteins. These repressors can be (1) viral encoded gene regulatory protein or (2) bacterial gene regulatory protein.

1. (b) 3. 1. Viral Encoded Gene Regulatory Protein

[0039] The bacteriophage lambda repressor, is a gene regulatory protein encoded by a bacterial virus. It shuts off the viral genes that code for the protein components of new virus particles. Thus it enables the viral genome to remain as silent occupier in the viral chromosome and multiplies along with the bacterial growth. Lambda repressor is one of such regulatory proteins which are encoded by bacteriophage lambda. This lambda repressor shuts off the viral genes that code for the protein components of new virus particles, and there by makes the virus genome inactive in the bacterial chromosome. But the mutant bacteriophage lambda cannot shut off the specific set of genes. With the help of DNA sequencing and DNA foot print studies it has been found that these regulatory proteins are bound to specific DNA sequences close to the genes which they regulate (Gilbert and Muller-Hill, 1967; Jacob and Monod, 1961; Kaiser, 1957 & Ptashne, 1967).

1 (b) 3. 2. Bacterial Gene Regulatory Protein:

[0041] The lac repressor is the first bacterial gene regulatory protein to be recognized. These generally respond when there is a nutritional requirement and they respond by shutting off genes encoding specific sets of metabolic enzymes when they are not necessary. Thus when sugar is absent in the medium, lac repressor turns off the production of the proteins responsible for lactose metabolism, (Jacob and Monod, 1961 & Gilbert and Muller-Hill, 1967).

1. (b) 4. Growth Factors Regulate the Protein Synthesis:

[0043] The growth factors regulate the protein synthesis and stimulate the cell/proliferation. Most growth factors also stimulate cell growth. (Loughlin and Fallon, 1992 and Purves, 1988).

1. (b) 5. Cells Enter Into Non Growing State—“G Zero” in the Absence of Growth Factors:

[0045] Mammalian cells stopped growth between mitosis and S phase, when they are deprived of serum which contains highly specific proteins called Growth Factors. In the absence of serum these, cells will delay division by entering a specialized non growing state called “G zero” (Pardee, 1974 & 1989).

1. (b) 6. Cell Senescence:

[0047] Cells from mammalian tissue cultures can be propagated only for a certain number of cell divisions (50 divisions for human cell cultures), after wards they cease to divide and die. This process is called cell senescence. But some cells derived from rodent tissue cultures escape senescence and divide indefinitely to produce cell lines (Todaro and Green, 1963).

1. (c) Hypothesis Linked to the Above Cited Literature:

[0049] Similar to the reference cited above the mammalian gene(s) taken up by the roots of the plants can remain as silent occupier, in the plant/heterogenous species, as the gene regulatory proteins switch off the foreign genes, or the cells may cease to divide due to cell senescence. It will only multiply and provide the original specific gene expression, . with phenotypic and genotypic characters, if it enters a homologous host and under suitable internal or external environment.

[0050] When the root of the plant takes up the (dominant) genes of other species from the soil, these foreign (to the plant) genes will lie in a latent state as lambda bacteriophage is integrated into E. Coli. These genes foreign to the plant may then enter into other species (humans/animals) through the consumption of the plant products, containing genes of other species and will be passed on to a different species (humans/animals/birds). The gene regulatory proteins can switch on or off specific sets of genes, depending upon the homologous host cell in which the gene is integrated. Parmley et al. (2007) recently reported that a secondary function of some pieces of DNA has the capacity to hold back the function of production of the protein, by keeping a check and slowing the process of associated genes, becoming ideal protein machines.

[0051] Experiments proposed: Experiment 1. 1. Study to find out whether the plant roots take up the human genes from the soil and get integrated into plant chromosomes.

Step 1. Objective:

[0052] To find out whether the plant roots will take up the human genes through its root and get it integrated into the plant chromosome.

[0053] Method: Conduct a DNA test of the person who is willing to participate in this study, using the commercially available ISO approved test kit. “The test will have the 16 DNA genetic markers including the 13 markers used by the FBI and other law enforcement agencies for human DNA testing. The 13 markers are referred to as the Combined DNA Index System (CODIS). All of these 13 markers are used only in the determination of human identity” (GTL, 2008). Conduct the experiment planting the seeds of paddy, wheat or carrot, in fresh soil containing only chemical fertilizer and organic nutrients from placenta, blood and or urine sourced from the above single person with known DNA profile.

Step 2.

[0054] At the fruit bearing age of the plant, the parts of the plant like leaves, stem, fruits etc. will be collected and send for gene testing/mapping, to the Plant Genome Mapping Laboratory (PGML), University of Georgia. If the results show that the human genome is integrated into the plant chromosome and present as latent human gene in the seeds of paddy, wheat or carrot, the following experiment will be conducted.

Experiment 1. 2. 1.

[0055] Study to find out whether the latent human transgenes in the plants are transmitted to animals through consumption of transgenic plant products (underground stem/fruits).

Objective:

[0056] To find out whether the underground stem/fruit of the transgenic plants carrying the human genes in the plant chromosome will be present as latent gene in the blood/gonads of mice/rabbits, when the transgenic plant product (rice, wheat carrot) are consumed by mice/rabbits.

Method: Experiment 1. 2. 1. 1. (Transgenic Wheat Plant):

[0057] Take one group of six (3 male and 3 female) Swiss albino mice of 3 weeks old. Keep them in separate cage with tag No. Collect the blood and conduct DNA test for base line data. Feed each mouse with wheat (harvested from the experiment 1.1, containing the human genes as integrated part of the plant chromosome) and water for 3 months. Collect duplicate sample of blood from each mouse at month interval and conduct DNA test to find out the presence of human latent gene.

[0000] Experiment 1. 2. 1. 2. (Transgenic Rice plant):

[0058] Take second group of six (3 male & 3 female) white mice of 3 weeks old. Keep them in separate cage with tag No. Collect the blood and conduct DNA test for base line data. Feed each mouse with rice (harvested from the experiment 1.1—containing the human genes as integrated part of the plant chromosome) and water for 3 months. Collect duplicate sample of blood from each mouse at month interval and conduct DNA test to find out the presence of human latent gene.

[0000] Experiment 1. 2. 1. 3. (Transgenic carrot):

[0059] Provide one group of six (3 male & 3 female) rabbits of one month old, each with carrot (harvested from the experiment 1.1—containing the human genes as integrated part of the plant chromosome) for 3 months. Keep them in separate cage with tag No. Collect the blood and conduct DNA test for base line data. Feed each mouse with carrot (harvested from the experiment 1.1) and water for 3 months. Collect duplicate sample of blood from each rabbit at month interval and conduct DNA test to find out the presence of human latent gene.

Experiment 1. 3.

[0060] Study to find out whether the human latent genes noticed in the blood of transgenic mice/rabbits will be transferred to their offspring.

Experiment 1. 3. 1.

[0061] At the end of the 3 months experiments, the animals whose blood showed positive for human latent gene will be grouped (separate for each food) together to breed and produce offspring. After weaning, test the blood of the offspring for human latent gene. Then euthanize the parent animals to harvest the gonads (testes and ovary) and send them for DNA testing, to confirm human latent genes in the gonads.

CONCLUSION

[0062] Finding human latent gene in the mice/rabbits and their progeny will be a proof of the “Gene Re-cycling”.

[0000] II. Natural phenomena:
Cyclic development of viral diseases.

[0064] Present scientific view is that the pathogenic bacteria/viruses exist in animals or birds as they become carriers of bacteria/viruses (host—parasite balance) without producing disease. Under adverse environmental conditions the disease outbreak occurs, due to the break down of immunity in those carrier animals/birds causing the cyclic development of disease outbreaks. Friedman (1992) reported that viral chromosomes can integrate into host chromosomes. The viruses which are integrated into the plant chromosome need not multiply immediately, but goes into a latent state and remain as inactive in the plant cells as provirus. It will come active only under suitable conditions sometimes after passing through several hosts/generations.

[0065] Hypothesis: The viruses/bacteria in the dead bodies of the humans/animals or the human/animal excreta, will be taken up by the roots of the plants grown in the soil in that area, get integrated into the plant chromosomes. The cyclic outbreak of certain viral diseases can then be attributed to the release of the viruses integrated into the plant chromosome, when such plants or its part/fruit are consumed by susceptible (immune compromised) humans or animals, resulting in an infection in the people/animals leading to fresh outbreak of the viral/bacterial infection in that area. The delay in the outbreak may be due to the time the virus/bacteria takes to travel from the roots to fruit/plant parts and the chance occurrence of a susceptible person/animal, eating the affected plant part. It is also important to note that certain plants like coconut trees/jack fruit trees etc. will take 5-8 years to bear fruits.

II. Supporting Literature:

[0000]
1. Viral Chromosomes Integrate Into Host Chromosomes:

[0067] The viral chromosomes after entering a host cell, necessarily need not multiply to produce more viral progeny. Because the genomes of these viruses enter into a latent state and become inactive in the host cell without producing any progeny. This viral latency was found out when uninfected bacteria, on exposure to UV light was able to induce the production of progeny of bacteriophages. Subsequently it was shown that these uninfected bacteria (lysogenic bacteria) carry in their chromosome, a complete viral (bacteriophage) chromosome lying in a dormant state. These types of host integrated viral chromosomes are called “provirus”. Bacteriophages which can integrate their DNA into bacterial chromosomes are called as temperate bacteriophages. Bacteriophage lambda is a temperate bacteriophage and when it infects a suitable E. coli host cell, it can grow either by lytic or lysogenic pathway. In the lytic path way lambda multiplies to several progeny particles and they will be released when the E. coli is lysed. In the lysogenic pathway, the integrated viral DNA replicates along with the host chromosome and produce new integrated viral DNA copies, resulting in the development of a lysogenic bacterium. This lysogenic cell multiplies in the normal way. But when it is exposed to any environmental insult/changes like exposure to UV light, or ionizing radiation, the cell becomes fragile/weakened leading to the release of the integrated provirus from the cell chromosome. Then it will lead a normal cycle of viral multiplication. It shows that the integrated provirus will not perish along with its damaged host cell, but can escape to infect other E. coli Campbell (1993).

[0068] Hypothesis: As per the literature cited above the mammalian/human gene(s) taken by the roots of the plants can integrate itself into plant chromosome and will remain as an integrated gene. The integrated foreign gene will be released from the plant chromosome, when the plant products are consumed by humans/animals etc. or cause any physical or chemical injury to the plant cell due to any environmental changes like extreme heat or cold or change in the nutritional status of the plant. Then the gene released from the plant chromosome will then follow the lytic or lysogenic path way and will lead to the escape of the released gene to other species. When the gene enters a heterologous unrelated species of organism, the gene regulatory proteins will switch off the foreign genes entered into unrelated host. If the gene released from the plant cell entered into a new suitable homologous species, related to the gene's original host, the gene regulatory proteins will be switched on.

[0069] To explain it further, the human gene integrated into the plant cell chromosome, when released by the consumption of humans, the gene(s) will enter a new cell in the human body, it will be expressed providing the phenotypic and genotypic characters of the gene remained in the plant chromosome as integrated gene.

[0000] III. Natural phenomena: Transmission of Prions (PrP Gene) Through Food and Hereditary:

[0070] Feeding “Renderers meat” with sheep offal, contaminated with Scrapie (PrPsc) produce BSE infection/mad cow disease in beef cattle. Consumption of beef infected with BSE/TSE prion (aberrant protein) will produce vCJD infection in humans. The causative agent of BSE/TSE is believed to be a small protein infectious particle (prion) which resist inactivation by the methods capable of destroying nucleic acids. The recent discovery that only a protein can cause and transmit the disease is shocking to the molecular biologists and virologists.

[0071] Hypothesis: As prions are transmitted through food and hereditary, the genes integrated into the plant chromosome when consumed by the animal or humans, will also produce gene expression in the animals/humans, if the gene is homologous or continue to remain as latent gene as in the case of prions (production of a slow latent infection).

III. 1. Supporting Literature:

[0072] Feeding “Renderers meat” with sheep offal, contaminated with ovine prion protein (PrP) gene in scrapie (Shiquan, et al. (2002) produce BSE infection/mad cow disease in beef cattle. Consumption of beef infected with BSE/TSE prion (aberrant protein) will produce vCJD infection in humans. Humans can be infected by Prions either as acquired through diet and surgical procedures or through “apparent hereditary Mendelian transmission where it is an autosomal and dominant trait” (Alan Cann, 2005). Prions are responsible for a slow developing disease due to the latent infection. It can be compared to the latent gene/host integrated viral chromosomes or provirus/bacteriophage lambda (Campbell, 1993).

IV. Natural Phenomena/Mythology:

[0073] Re-incarnation myth becomes a scientific reality due to modern scientific biotechnology success in cloning, and Transgenesis.

[0074] In India there are so many stories of re-incarnation/re-birth of a person in another part of India or world. Re-cycling of genes is probable explanation for the myth of re-incarnation. It is possible to explain hypothetically that the dominant genes of “X” person's cadaver integrated into the soil, when taken up by the root of the plant, will remain as latent genes in the plant part/fruit. If the plant part is then taken up by another person and entered into the gonad of another person, the phenotypic and genotypic character of the dominant gene of the “X” person will be expressed in the progeny as rebirth/reincarnation of the “X” person.

[0075] Re-incarnation story give strong support to the Gene Recycling Hypothesis.

[0076] Gene re-cycling hypothesis can be the scientific/nature's explanation for the Hindu mythological stories on people with animal face/head and human body or female body with fish tail (Mermaid) manifested as nature's freak, due to incomplete expression of human gene(s), integrated into animal chromosome (transgenic animal) or vice versa. Traditionally many people attribute such nature's freak is endowed with God's power Cherubim is a typical example for transgenic person with incomplete expression of genes from other species like animals & birds. It is also possible that the human gene is carried by another animal as shown in the movie of the dog “Fluke”.

V. Natural Phenomena:

[0000]
Reappearance of the Extinct Animals and Birds:

[0078] Cell theory of 19thcentury stated that all living organisms possess cells and the new cells are developed only from the existing cells. Thus all Eukaryotic or Prokaryotic unicellular or multi cellular organisms are developed through the evolution from an original population of primitive “cells”.

[0079] Hypothesis: New cells will be developed by recycling the genes of the previous generation of living organisms existed earlier on earth. The well-known saying “Life comes after death” should be a scientific fact. The animals and birds once lived on earth after extinction may come back again to life through the recycling of the genes deposited in the humus and remained as integral part of the soil. The plants grown on such soil with the genes of the extinct animals and birds, may take up the genes through its roots and can remain in the leaves and fruits. When animals/birds of other species eat the leaves/fruits, the genes of extinct animals/birds, may enter the body of the new host and by entering the ova/sperm may re produce the life of the extinct species. Recently it has been reported that Black footed Ferret which was extinct has been found recently.

VI. Biblical References: Genes in the Trees, Stones and Bones:

VI. A. Genes in the Tree—Tree of Life: Garden of Eden:Bible (1973). Genesis Ch. 2, Verse 8 and 9.

[0080] “8. And the Lord God planted a garden toward the east, in Eden; and there He placed the man whom he had formed.

[0081] “9. And out of the ground the Lord God caused to grow every tree that is pleasing to the sight and good for food; the tree of life also in the midst of the garden, and the tree of the knowledge of good and evil”.

VI. B. Forbidden Fruit: Does the Fruit From the Tree in the Garden of Eden Contained Gene to Know Good and Evil?

[0082] Bible (1973). Genesis Ch. 3. verse 2-5.
“2 And the woman said to the serpent, “From the fruit of the trees of the garden, we may eat;

[0083] “3. but from the fruit of the tree which is in the middle of the garden, God has said, ‘You shall not eat from it or touch it lest you die!

[0084] “4. And the serpent said to the woman, You surely shall not die!

[0085] “5. For God knows that in the day you eat from it your eyes, will be opened and “you will be like God, knowing good and evil”.

[0000] VI. C. Gene expression—Tree of Life: Disobedience and Fall of Man and Woman from God's Grace: Bible, 1973: Genesis Ch. 3, verse 22-24.

[0086] “22 Then the lord God said, “Behold, the man has become like one of Us, knowing good and evil; and now, lest he stretch out his hand, and take also from the tree of life, and eat and live forever”—

[0087] “23 therefore the Lord God sent him out from the Garden of Eden, to cultivate the ground from which he was taken.

[0088] “24 So He drove the man out; and at the east of the garden of Eden He stationed the cherubim and the flaming sword which turned every direction, to guard the way to the tree of life”.

[0089] Hypothesis: The above Biblical passage gives us the insight that God intended that man and woman to lead an eternal life by eating the fruit of “the Tree of Life”. But since man and woman disobeyed God and sinned, He threw them out of the Garden so that they will not have eternal life, simply by eating the fruit. Instead they (we) have to toil in the soil and go back into the soil, so that our gene will integrate with the soil and will regenerate again into humans with the gene integrated in the trees/plants/fruits rooted in the same soil. Thus each tree by taking the human genes from the soil with their roots, become the symbolic of the tree of life of the Garden of Eden.

[0090] Thus through the recycling of genes through the plants/tree of life, humans have eternal life and will have several opportunity to become self purified to receive the

[0091] Lord Jesus when He comes 2<nd >time. It can be presumed that each civilization on this earth is a re-incarnation of the previous civilization. If each person on this earth is a new entry into this planet, God must have created several billions or trillions of people, but through recycling of genes most probably, we are all born repeatedly on this earth (re-incarnation/rebirth?).

VI. D. God Can Raise Up Children From Stones:

[0092] Bible (1973). New Testament; Matthew Ch. 3, verse. 9 “and do not suppose that you can say to yourselves, We have Abraham for our father; “for I say to you, that God is able from these stones to raise up children to Abraham”. We cannot simply ignore this as a statement by John the Baptist out of his anger or frustration. If we read it in between the lines, then we can understand or presume, that the soil and the stones may contain the genes of the human beings, hence John the Baptist knowingly or unknowingly said that God can raise the people from the stones/soil.

[0093] Hypothesis: If we understand that every flora and fauna seen on the earth are mortal and become part of the earth after their life span, then we should also know that new life on earth starts not only by recycling the nutrients but also by genes of the dead flora and fauna.

[0094] The well known fact: "LIFE COMES AFTER DEATH", will be supportive of the hypothesis that genes of every flora and fauna are recycled from generation to generation.

[0000] VI. E. Ezekiel's Prophesy of Life from Dry Bones:
Bible (1973). Ezekiel—Book of Ezekiel: Ch. 37. verse 1-14,

[0096] "The hand of the lord was upon me, and He brought me out by the Spirit of the Lord and set me down in the middle of the valley; and it was full of bones.

[0097] "2 And He caused me to pass among them round about, and behold, there were very many on the surface of the valley; and lo, they were very dry.

[0098] "3 And He said to me, "Son of man, can these bones live?" And I answered, "0 Lord God, Thou knowest."

[0099] "4 Again He said to me "Prophecy over these bones and say to them, O dry bones, hear the word of the Lord."

[0100] "5 Thus says the Lord God to these bones, Behold I will cause breath (spirit) to enter you that you may come to life.

[0101] "6 And I will put sinews on you, make flesh grow back on you, cover you with skin, and put breath in you that you may come alive; and you will know that I am the Lord."

[0102] "7 So prophesied as I was commanded and as I prophesied, there was a noise, and behold a rattling; and the bones came together, bone to its bone.

[0103] "8 And I looked and behold, sinews were on them and flesh grew, and skin covered then: but there was no breath in them.

[0104] "9 Then He said to me "Prophecy to the breath, prophecy son of man, and say to the breath, "Thus says the Lord God, "Come from the four winds, O breath and breathe on these slain, that they come to life."

[0105] "10 So I prophesied as He commanded me, and the breath came into them, and they came to life, and stood on their feet, an exceedingly great army.

[0106] "11 Then He said to me "Son of man, these bones are the whole house of Israel; behold they say, "Our bones are dried up and our hope has perished. We are completely cut off.

[0107] "12 Therefore prophecy and say to them "Thus says the Lord God, "Behold I will open your graves and cause you to come up out of your graves, My people; and I will bring you unto the land of Israel.

[0108] "13 " Then you will know that I am the Lord, when I have opened your graves and caused you to come up out of your graves, My people".

[0109] "14 "And I will put My Spirit within you and you will come to life, and I will place you on your own land. Then you will know that I the Lord have spoken and done it, "declares the Lord."

SUMMARY

[0110] By applying modern science and technology knowledge, it is hypothesized that “Genes of every flora and fauna are recycled from generation to generation through the plants, humans, birds and animals living in land and water”. Gene Recycling plays the most crucial role in the continued propagation of flora and fauna on our planet. Through gene recycling, biosphere is made to immortal existence. This is a postmodern century of interrogation. Gene Recycling Hypothesis can provide full or partial answer for many of the nature's phenomenon we now see in the world.

MEDICALLY PERPETUAL PERSISTENCE OF ESSENTIAL HUMAN LIFE

Inventor: CHOUDURY SPANDAN
Also published as: WO2009147634 // GB2475181

This Patent Application presents a biomedical mechanism of feasibly effecting tangible human immortality. The applicant believes that this technique is the only feasible and meaningful means of effecting perpetual persistence of human life. It forgoes all modern day approaches in the world up to now that target medical mechanisms to extend the life span of the body, and instead adopts a fundamentally novel innovation by way of enabling the biomedical transfer of the cognition that essentially constitutes a human to a different body prior to the death of the original body, whereby the transfer is NOT a copy of (and hence what would otherwise NOT be) the essential original human but IS the essential original human itself.

FIELD OF INVENTION

[0003] The field of invention is biomedical engineering. It primarily, but not only, involves neuroscience and electrical engineering. A novel, and possibly the ONLY feasible, means of effective persistence of human life for perpetuity is presented.

BACKGROUND OF INVENTION

[0004] As indicated above, the applicant deems it futile of anyone to attempt to keep the human body alive perpetually—THAT WILL NEVER WORK. EVER, although it will be possible to increase the relative duration of the longevity of the body. It is a reasonable expectation that regardless of the state of research even millions of years from now, each body WILL die some time, either from old age, or external events (including diseases caused by external events, accidents etc). That, is because given the virtually unlimited count of interacting variables involved inside and outside a body to keep it alive, it will forever be impossible to successfully manage them all for eternity.

[0005] This Patent Application presents the applicant's novel invention on a practical mechanism of essential persistence of life for perpetuity.

[0006] The applicant sees two perspectives to human immortality—

A. Immortality only from the perspective of people that knew the original human, but not from the perspective of the original human.
B. Genuine immortality from the perspective of the original human.

[0009] The applicant infers that while it will in principle be technically feasible soon to transfer the cognitive and sufficiently important individual-defining non-cognitive contents of the human brain to a new brain (or another equivalent entity) whereby the people who knew the dead human would perceive the new entity containing the transferred data as essentially having simulated the original human, the key flaw in that approach is that the original human being will NOT feel as having continued life in the new entity—the original human's sense of self identity “I” would not be transferred into the new entity. Instead the second human's sense of self identity would be of a new “I” that would be a reasonable COPY of the original human's identity, and there could in principle be an unlimited count of such copies across multiple entities. That, however, does not constitute genuine immortality. In short, if the original human was “Mary” or “James” the second entity would still say “I am Mary” or “I am James”, but the original Mary or James would not accept the respective second entities as them, both when the original Mary or James are still alive and after their body-death. For purposes of this Patent Application, the original human will be referred to as “Mary-I”, while the second human per “A” would be “Mary-II-A”, and that per “B” “Mary-II-B”. This Patent Application pertains to the creation of Mary-II-B.

SUMMARY OF INVENTION

[0010] This Patent Application is on the second perspective (“B.”) listed in the previous section, whereby the original human Mary-I would actually recognize herself as having been transferred into the new entity, with that entity being preferably a regular human brain attached to a regular human body.

[0011] There will be a common period of time prior to Mary-I's body-death when Mary-I and Mary-II-B would both be simultaneously alive, and while still alive Mary-I will be able to confirm her being able to recognize the (foreign) memory and cognition of the second brain and sense input from the second body. Mary-I will in effect be able to use not only her own brain's resources (i.e. her brain hardware and data) and input from the senses of her own body, but also be able to use the resources (i.e. brain hardware and data) of the second brain and receive input from the senses of the second body. Then, per the mechanism described in this Patent Application, Mary-I will willfully “transfer” her memory and consciousness to the second body. Of course, the people around the original human (Mary-I) would deem the second human (Mary-II-B) as essentially being even more of Mary-I, than would be the case with Mary-II-A.

SUMMARY OF DIAGRAMS

[0012] FIG. 1—Demonstrates a sample neural network of 8 brains, including Mary-I's original, that forms an integrated, single, logical, augmented center of consciousness. As indicated, upon subsequent physical delinking, ordinarily at most only one of the 7 other brains can manifest Mary-II-B, while each of the remaining 6 can at most manifest Mary-II-A. Arrows indicate direction of flow of information, hence the direction of consciousness transport prospect, albeit the invention recommends dual-directional rather than unidirectional arrows in each case. Of course, the at-most-single Mary-II-B brain is only in as much as that only a single, logical, (augmented or diminished) integrated center of consciousness can be created to control one brain or a set of linked brains—and so it is optionally possible to have Mary-II-B to be created across multiple brains that are combined to form a single, integrated, logical center of consciousness. There will still ever be only ONE Mary-II-B, regardless of whether or not she is created in one brain or across multiple brains. The latter would not be recommended because of the logistical inconvenience that would be associated with the need to have multiple brains constantly communicate towards maintaining that logical, integrated center of consciousness.

[0013] FIG. 2—Demonstrates a sample neural network of 8 brains, including Mary-I's original, that forms an integrated, single, logical, augmented center of consciousness, whereby, upon subsequent physical delinking, while only one (ordinarily the maximum count permissible per this invention's inference) of the 7 other brains manifest Mary-II-B, only 3 of those 7 other brains manifest Mary-II-A and the remaining choose to retain their respective original identities. Arrows indicate direction of flow of information, hence the direction of consciousness transport prospect, albeit the invention recommends dual-directional rather than unidirectional arrows in each case. Again, the at-most-single Mary-II-B brain is only in as much as that only a single, logical, (augmented or diminished) integrated center of consciousness can be created to control one brain or a set of linked brains—and so it optionally is possible to have Mary-II-B to be created across multiple brains that are combined to form a single, integrated, logical center of consciousness. There will still ever be only ONE Mary-II-B, regardless of whether or not she is created in one brain or across multiple brains. The latter would not be recommended because of the logistical inconvenience that would be associated with the need to have multiple brains constantly communicate towards maintaining that logical, integrated center of consciousness.

[0014] FIG. 3—Part of hippocampal circuit pertinent to IBC

[0015] FIG. 4—Part of Papez circuit pertinent to IBC

[0016] For descriptive legends on one or more of the figures see subsection “Descriptive legends on figures” towards the end of the section “DESCRIPTION OF INVENTION”

DESCRIPTION OF INVENTION

[0017] What is self identity and how is that relevant to perpetual persistence of life?

[0018] In the context of this invention it would be relevant to understand precisely what constitutes one's being aware of oneself and hence one's existence. While the views presented in this section are entirely the applicant's own, they do NOT by themselves constitute the invention itself, but instead justify/prove/validate the invention.

[0019] The first step towards that understanding would be to analyze if a human brain soon after conception were in principle medically isolated from all possible forms of input (to the brain) for decades afterwards while still being artificially provided all forms of nutrition to keep it medically alive and cause it to physiologically mature as brains would normally grow would at all have a consciousness and consequently have a sense of self-awareness. In other words, could a human brain develop consciousness when right from its inception it ceased to have absolutely any auditory, visual, olfactory, taste or tactile or absolutely any other form of input—the latter including a sense of pain, pressure, vibration etc. (which essentially are appropriate combined or singular renditions of the fundamental five senses anyway)? Regardless of whether that brain would still have medically “awake” and “sleep” cycles, including cycles of dreams, what could that brain base its consciousness on?

[0020] To answer that, one could ask oneself how one recognizes oneself cognitively immediately upon waking up from sleep. That awareness is from independent, corroborating recent (and sometimes past) memories of incidences, in addition to corroborating new input from the five senses with memories already in the brain of similar prior input (e.g. the visual/auditory input on surroundings being either similar to or different from what is already in memory, etc). Hence there need be some memory for self awareness. Memory is accepted as valid memory (and not imagination) with a high degree of conviction when it can be corroborated with other memory—and therefore the reality of memory is that each experience typically gets laid down in long term memory as a set of independent memories that effectively corroborate (and therefore reinforce/validate) each other—e.g., the memory of having simply sat in a chair somewhere could be recalled from various separate sitting-/time-/surroundings-/etc. angles, hence when recalling that experience one would essentially corroborate across multiple memories of that experience and therefore reasonably assess that one did indeed sit on that chair. In contrast to that, if all one recalled from that experience was just One Single Static memory of sitting on the chair, one would fail to adequately corroborate that memory with other memories of the same experience, and hence one would reasonably question the accuracy of that memory. The fact that most incidences are perceived across a span of time, however short, enables a memory of each such incident to be laid down as a set of corroborating memories, and of course the more intense an experience the greater would be the information content and count of such independent, corroborating memories. It could be noted that the count of memories of any experience would also increase with the intensity of that experience, even if the core incident behind that experience was fleeting. That is because the intensity of the experience would enable the individual to accept input (to be mentally tagged to that experience) on that experience for an appropriate period even after its occurrence. For example, if a person accidentally suffers a cut to a finger from a very momentary lapse of concentration while, say, cutting a piece of fruit to eat, the consequences of that cut would substantially add to the memory content of that experience, which would all be appropriately considered later for independent mental lookup and corroboration towards ascertaining whether one did indeed cut one's finger. As the brain continually lays new memories appropriate to the perceived significance of an experience, the longer an experience persists, and the more significant an experience is assessed to be at and shortly following the time it occurs, the more separate (yet linked, as they relate to the same event/experience) memories of it would be laid down that can later be collectively accessed for a corroborative validation on if the recalled past event/experience's having actually occurred. Each of those memories is built with various layers of the “knowledge framework of rules” (with basic rules at the lowest layers, and at the upper layers are more complex rules created using the relatively lower layers' basic rules and other rules of typical complexity not more that itself) that one gradually first develops at early childhood and continues developing on subsequently for one's entire lifetime (forming more and more complex rules). As particular complex rules are used more often, they themselves get directly interpreted to major extents without requiring referring the lower rules for interpretation, therefore increasing the speed of processing of related complex experiences. In short, self awareness requires memory, and for memory to form there have to be experiences, which are impossible in the absence of external input. It is important to recognize that if there is even a tiny amount of any input given to the brain at any time (e.g. in the case of any individual who might be born regular, but soon looses all physical senses within a day of birth), the brain would take that minimum information that was available for a day and naturally proceed to build up on that towards continually generating newer information databases—and in that case the brain WOULD be conscious. That build up of new information in that stated particular brain would largely be abstract of course as additional external input would be absent that would otherwise have enabled the buildup of a framework of a pool of rules adequately reflective of “reality”, but the brain would still develop an altered consciousness “in a world of its own”. It is significant to note that that state of abstraction is NOT truly unreal per se, but it is abstract in the context of the “real” world that regular humans live in. The human brain is designed to accept external input, however minimal, and, based on its significance, appropriately process the information contained in that input towards not only optimizing the subsequent application of the perceived rule(s) contained in that input, but also develop more complex rules premised on the basic rule(s) as voluntary and deemed necessary choices in anticipation of a need to apply such complex rules.

[0021] Therefore in the complete absence of all forms of external input, the applicant infers that it is logical that that brain would fail to have a meaningful form of consciousness.

[0022] There would essentially be no meaningful functional difference between its states of wakefulness and sleep, even if the brain goes through biological sleep and wakefulness cycles anyway.

[0023] The above conclusion is based on the hypothetical premise of a complete absence of external input into the neurons of the brain since the neurons' conception. In reality, that scenario is virtually impossible, because at the least the neurons Would be able to sense medical variations of the state of the brain itself as “internal” input that would be processed and developed upon towards an abstract perception of consciousness. In fact, even artificially rendering permanent unconsciousness to the brain since inception wouldn't make possible that state devoid of all input, since as long as the neurons are alive they would still automatically collect information from its surroundings, including, from within the brain itself, as well as from within itself. Of course the quality of consciousness would vary depending on the quality of input that it is based on.

[0024] However, the above conclusion is relevant to establishing the fact that being aware of the self and therefore being aware that one is alive mandates that the brain receive external input over a period at some point (at least in the past), as is enumerated further below. The mind of a regular human associates its sense of "I" with a virtually limitless count of memories that it can validate each of either entirely from other memories already in the brain related to the same event/entity/experience and/or with new input from the five senses. For example, one of those associations with one's self identity could be—"I recall having placed my finger on a cube of ice in the freezer compartment of my kitchen refrigerator a week ago, and my finger felt very cold" and "I recall placing my hand on a block of ice in the supermarket ten years ago and my finger did feel cold" and "Let me go touch snow ice that has collected outdoors in my garden this winter morning and let me try to experience if it indeed feels cold to the touch". Each of those two memories correctly corroborate with each other affirming the individual's belief in the validity of those memories and therefore in the individual's identity of self. This is further reinforced by subsequently determining that snow ice feels the same to the touch. When the brain is totally relaxed, yet awake —that bandwidth of the sense of "I" tends to narrow (in the sense that there's a lower count of memories of the self active uppermost in the mind). When there's total amnesia of past memories and a complete loss of the ability to lay down new long term memories, one loses one's sense of identity completely, yet one can still function for basic tasks with short term memory (which do not contribute to one's self identity). A further degeneration of brain abilities would ultimately lead towards a gradual to a complete loss of even the ability to function.

[0025] A highly relaxed, awake human mind is of course not always entirely aware of its identity at any of the uppermost predominant layers of consciousness. Such periods typically are no longer than a short few seconds. That state is different from when the mind is so focused in other deliberations that one's awareness of one's own identity ceases to be a priority consideration for the duration of that focus, which also typically is no more than a few seconds. However, in a matter of seconds, in either case, one's identity comes actively back in one's mind at the appropriate upper level(s) of awareness. Of course since the levels of awareness in one's mind are made up of various layers consciousness (most conscious at the highest and least conscious at the lowest), self awareness is manifested only in the appropriate layers, commensurate with the significance of the need to be self aware (per the ongoing deliberations in one's mind, and where relevant the external input as well). It is to be noted that even while one might not be consciously aware of the more profound aspects of one's identity during the stated periods of intense alternative focus, one still retains a form of self awareness in more simple parameters—by comparing incoming external input with short- and long term memory of the same input. For example, that awareness continuity could be in the form of a breeze blowing across one's face before and then, or some background sound persistent before and then, et al.

[0026] Therefore, what a human cares for in as much as being alive is to be able to CONSCIOUSLY refer back—and therefore naturally corroborate across—as many of those memories as is possible, in the process not only consciously and subconsciously affirming the individual's self identity but laying new memories (in the form of plans, etc) towards feeling positive about one's self identity in the long run on the whole. The latter is of course achieved in a complex combination of learnt behaviors (outside the scope of this Patent Application) that ultimately release the "feel good" neurotransmitter et al chemicals in the brain (e.g.

[0027] (A). learning that society currently affirms that one must love and take good care of one's child and therefore one must do good to one's child, based on which genuine love for the child develops (albeit that love also develops in the absence of society based on other aspects related to memory in the human mind), therefore doing good to one's child or seeing the child happy releases those feel-good chemicals in the brain.

[0028] (B). learning that society encourages success, hence planning for and attaining success releases those feel-good chemicals in the brain.

[0029] Therefore, that self identity (and not the brain hardware associated with it) is what constitutes being a particular human, and it is that self identity that the invention described in this Patent Application focuses on perpetually transferring sequentially, towards life's persistence in perpetuity. To be noted is that brain hardware is of course critical for that identity processing to be done, and subtle variations in the hardware of the brain would cause subtle changes in the perception of one's self-identity even with everything else remaining the same—for example if a pair of (genetically identical) clones were kept in the same environment since inception, they would NOT develop to have the exact identical memory banks or personality. However, the applicant infers that most brains' hardware is acceptably identical within reasonable limits in the context of this processing (distinguishing a human brain from, say, a dog's brain or—as an extreme incompatible example—a latest modern day supercomputer), rendering it possible that most brains be acceptably compatible to process that transferred self-identity in as much as their being able to reasonably manifest the original human's self awareness and traits.

[0030] For feasibility, this invention uses the brain's existing abilities and properties towards that transfer, as elaborated subsequently in this Patent Application.

[0031] The quality of human consciousness containing (by definition) one's self identity, even for the same individual, is plastic. There are multiple, non-discrete qualitative levels of increasing or decreasing consciousness. In all cases when one can reasonably identify oneself, one ultimately normally has a positive experience with one's being alive and awake, hence it would be any of these states of consciousness (where one can meaningfully identify oneself) that would need to be transferred in the context of immortality. However, when there is no sense of self identity at all (when, for example, there's total amnesia of past events associated with a complete inability to lay any new memory) even while the ability to otherwise fully function with short term memory alone is retained, the state would not be meaningful to transfer towards immortality because there is no self identity in such a case.

Key Feasibility Controls

[0032] At the core of this invention are the following controls that render this invention feasible—

[0033] (i.) The applicant's inference that what constitutes being any particular human is Not tied to any one physical brain, but the awareness of memory content and new external input towards direct and indirect self-recognition (i.e. consciousness of the self) and learned reactive rules (i.e. personality, which to a major extent is essentially a manifestation of consciousness of the self) (more importantly the former, because human personality can be modified/learnt later but critical information needs to be retained if self-identifying memories have to be passed on) that can each be Consciously (and Otherwise, primarily the former)—While the Original Brain is Alive—Rendered Familiar with a New Brain's Hardware and its Information Content, Integrated for Functioning (While Still Keeping the Original Information Separately Identifiable) with the New Information Content and Hardware of the Second Brain Along with the Original Brain Hardware. This Process can be Extended to Beyond a Set of Just Two Brains. Consequent to that and the other controls listed in this section the Applicant's Inference that any One Original Brain is able to Consciously (and Otherwise, primarily the former), Following the Stated Integration with One or More Additional Brains (& the Information Contained Therein), Choose One of Those Brains to Base its Consciousness (and therefore personality too) On. That is Based on the Fact that Each Individual Human Brain Constitutes a Reasonable Minimal Hardware that is able to Support Adequate Human Consciousness by Itself, Albeit the Quality of that Consciousness is Expected to be Slightly Inferior to the Integrated Consciousness Attained with Multiple Brains.

[0034] (ii.) The applicant's inference that there cannot be more than one integrated center of consciousness (that, by definition, acknowledges complete self identity) for any living entity at any one time. There can be multiple separate integrated centers of consciousness, each of which could in principle separately take complete control of one's entire core consciousness at different points of time, but only one can he the sole integrated center of consciousness at any one time. To rephrase, There can be at Most be One Logical (and hence PHYSICAL (which crucially doesn't entirely HAVE to be at one location—just that the constituent physical components need to not be physically delinked)) Center of Consciousness for any Living Entity at any One Point of Time. To rephrase, in the context of the human, when a set of integrated brains (manifesting an integrated center of consciousness) are physically delinked, the consciousness of that set can at best be transferred to AT MOST one human brain's center of consciousness (or—if chosen—an integrated, augmented logical center of consciousness formed of interlinked centers of consciousness of multiple regular brains) (and at worst to no human brain at all—the integrated consciousness, would just be destroyed), in as much as a human brain is considered the minimum (but NOT the maximum) physical hardware capable of adequately hosting a comprehensive center of human consciousness that (i.e. the consciousness) can be fully independent of reliance on any other hardware (i.e. any other brain), as is the case with every known regular human brain today. This for example, is to contrast the regular human brain from that of a primate in much as the latter being incapable of physically hosting a human-quality center of consciousness. Again, that is not to state that consciousness WILL be transferred to one brain even if not desired, but only that AT MOST one center of consciousness (spanning one or multiple brains) can have the integrated consciousness transferred to (if applicable/necessary at a slightly inferior quality, but adequate and comparable to the quality of consciousness in any regular human brain). Again, it is important to note that in principle it is 100% possible that if so elected an integrated center of consciousness can be transferred to span across multiple human brains whereby the multiple brains would either together host a SINGLE integrated center of consciousness or independently host separate centers of consciousness only one of which would take full control at any one point of time, however such would render this invention less practicable and less useful. because of the then need for perpetual communication and cooperation among multiple brains that typically would also imply the requirement of the same count of independent, perpetually collaborating humans.

[0035] (iii.) The already publicly recognized ability of the brain to attempt to functionally optimally (i.e. as best as is possible given the tissues and other aspects of the scenario) communicate with neurons not part of that brain, and with the quality of communication augmented in a technology enabled environment. This has been independently evidenced in various attempted-regenerative/“curative” procedures involving the cerebrospinal system.

[0036] (iv.) The brain's already publicly recognized ability to still function optimally (as best as is possible) without the original entirety of the brain, on account of information content multi-duplication and redundancy across the brain, brain hardware redundancy and brain hardware function flexibility. This is evidenced in cases of traumatic brain injury or surgical removal of brain components.

[0037] (v.) The (human) brain's already recognized ability to learn to do just about anything, with and/or without conscious will. There is ho dearth of evidence on the brain's remarkable learning abilities.

Specific Steps in Invention

Step 1—Link Brains to Communicate

[0038] [Key Feasibility Control Applied—(iii.)] (Ref. “Key Feasibility Controls”)

[0039] Mary-I is to be linked to the new brain.

[0040] The intention is that subsequently, per Step 2, Mary-I's brain naturally integrates (enabled by appropriate, minimal external technology support (Ref. “Technology supported interbrain communication”)), as far as optimal logical functioning, with the brain of the second individual towards jointly forming an augmented logical neural network, essentially aimed at rendering the two brains capable of functioning as one, while still maintaining their separate identities at will.

[0041] In order to be meaningful (for example for protection from transmissible terminal illnesses like hepatitis, cancer tissue, HIV etc) this integration will Not mandate a direct tissue connection, but instead can even be achieved with wires, or even entirely wirelessly.

[0000] Step 2—Learn to Use Other Brain, Towards Forming (Together with Mary-I's Own Brain) an Integrated, (Virtual) Single, Augmented, Logical Brain Containing an Integrated, Augmented, Logical Center of Consciousness
[Key Feasibility Controls Applied—(i.), (ii.), (iii.), (v.)] (Ref. “Key Feasibility Controls”)

[0042] This is the most critical component of this invention, whereby each of the two connected brains would, using a combination of the appropriate, minimal external technology support and optimal mental effort by way of using the brains' natural ability to learn and optimally integrate with new hardware, gradually recognize the hardware and information content of the other brain, towards forming a single, augmented, logical brain with a single, augmented, integrated logical center of consciousness.

[0043] That single, augmented, integrated logical center of consciousness will include, in whole or in (typically the most) part, the logical center of consciousness of each individual brain, and (typically) an additional consciousness component originally present in neither of the two original centers of consciousness. That additional consciousness component may preferably be reduced or eliminated for the integrated, augmented consciousness to maintain acceptable fidelity to the logical integration of the original set of consciousnesses.

[0044] The aim of this step is to establish one logical center of consciousness (while still consciously and otherwise retaining the separate identities) for the combined brain at any one point of time, such that it can be switched on or off at will (by the combined single logical center of consciousness, with (importantly—so that the rights and will of each original human are never compromised at any point) each original separate logical center of consciousness retaining full overriding control on its own share of original physical resources and original information content) to return back to the state of the two separate logical centers of consciousness. In short, the combined logical center of consciousness will happen only if both original separate centers of consciousness agree, while never losing awareness of and control on their separate original identities (i.e. on the separate original logical centers of consciousness), and should one of those identities wish to exit the combo it could. The combo would essentially remain an optimally integrated sum of two separately distinguishable parts that could choose to either separate or work together—with each maintaining the critical ability to recognize and influence the other. So there is an element of trust involved, necessitating a correct selection of the two original human candidates, and it would be meaningful that with that selection correctly done the logic of mutual- and overall good would largely prevent infraction of rights by the combined logical center of consciousness of its separate always identifiable component original centers of consciousness: in fact, it would also be easy for each brain's consciousness to willfully deny detrimental “takeover” against its will by another brain's consciousness, much though not exactly the same way for example the Autonomic Nervous System in any standalone individual optimally controls that individual's heart rate, digestion etc without direct conscious control by that individual's consciousness albeit the individual would still be appropriately aware of the individual's heart rate, digestion, etc. In other words, the consciousness combo in the combined logical center of consciousness would remain appropriately aware of each component center of consciousness and be able to control that component center of consciousness to an extent appropriately less than the extent of its awareness of it. As an additional option, that awareness by the integrated center of consciousness of each component center of consciousness and consequently of the human body originally attached to each respective component center of consciousness can be but does not have to be 100%—in other words it could be but doesn't have to be that sections of a component center of consciousness and consequently of the original human body attached to that component center of consciousness remain completely out of bounds of the integrated center of consciousness, not just in Step 2 but even at the conclusion of Step 3. That one logical center of consciousness could be physically located at either brain, or in both combined—of course ideally the former for portability logistics so that Mary-I's original brain hardware could be completely disregarded at will (if so chosen by the stated combined single logical center of consciousness, (pre-) approved by Mary-I).

[0045] After the two brains have been linked to communicate so that the process of logical functional integration could begin, the next step would be for Mary-I to consciously (and sub-/unconsciously) familiarize with the second brain's hardware's peculiarities and with the information content therein, and consequently "learn" to cogitate using "both" her existing brain as well as the second brain's hardware resources and information content. This process could last several hours up to multiple days (in sessions), in the earlier phases of implementation of this invention, and would expectedly very significantly speed up with improvements in supporting technology later. The stated processes of logical integration and learning by both the two brains would proceed at the same time. The neurons of the brains would know how to optimally integrate and function jointly, as long as a potent communication environment (outlined separately in this Patent Application) is provided. At the end of the process, the brains would be deemed to have provisionally been functionally integrated towards optimal logical operations as one (virtual) single, augmented brain. That virtual single brain would have two separate physical centers of consciousness of course (that would, at mutual consensus as part of the process of learning, switch off or on alternately and simultaneously as part of that learning), and Mary-I's brain and the other brain would each learn to recognize the logical consciousness center of the other brain, and as part of the familiarization process grant alternating permission for trial control of consciousness and data (i.e. retrieving and adding memory, processing new input from body etc.) by the other brain's center of consciousness. Essentially Mary-I's sense of self identity would now include recognizing new data and brain behavior that were not originally hers and which she would reasonably "tag" as such (i.e. she would not confuse new information in the second brain with her own original information in her brain, instead she would tag new information as not originally hers and simply learn to deal with that information while maintaining her identity in the integrated logical combo). As part of the integration, she would also learn to recognize and work with the other brain's different physical components and data therein towards manifesting her own original personality, to the extent that her original personality would need to be reasonably exhibited at will following the transfer. While a significant portion of the learning will be in conscious states, part of the learning will be in sub-/unconscious states as well. This process of "learning" towards a logically integrated single (virtual) brain with a single (virtual) logically integrated center of consciousness made up of the always identifiable separate original two logical centers of consciousness (with two physical centers of consciousness that will not always be either simultaneously awake or simultaneously asleep, by mutual consensus) where each brain learns to recognize and work with the other brain's physical components and data therein towards manifesting one's original self-identity and personality and other adequately significant aspects of oneself using one's own and the other brain's hardware, and identifies and tags the other brain's information content as not being one's own original memory, and with the combined single logical center of consciousness maintaining the ability to be switched on or off at will (by the combined single logical center of consciousness itself (or by one/more individual component original logical center(s) of consciousness where applicable), with (importantly—so that the rights and will of each original human are never compromised at any point) each original separate logical center of consciousness retaining full overriding control on its own share of original physical resources and original information content) to therefore enable a return to the original state of two separate logical centers of consciousness (if so desired), is the first significant step of this process. Post transfer, the traits of either Mary-II-B or the original second individual would be manifested at will whenever chosen. In effect, the “better” traits would ordinarily manifest (again, largely at will)—for example if Mary-I was level headed and the second individual originally was less so, then the combo would be level headed at will, and if Mary-I was poor in Math while the second individual was not then the combo would not have to be poor in Math.

[0046] The centromedian nucleus, which is part of the ILN (Intra-Laminar Nucleus) of the thalamus, is already recognized in the medical community today as an important center of consciousness in the human brain. Since, as part of the “learning” phase, the two separate brains would need aim to function as one with preferably hut not necessarily one physical center of consciousness (towards attaining the post-learning-completed requirement of having one logical center of consciousness for the combo at any one point of time, albeit with the combo's never losing awareness of the two separate identities), the applicant recommends enabling neural networking that allows the two centromedian nuclei and other separate components that all jointly constitute the two integrated centers of consciousness in the two brains to both remain functional (to allow for both the independent brains to learn to recognize and “learn” each other and consequently enable both operate jointly as one center of consciousness and also separately as two separate centers of consciousness that each brain would be able to sense both of), as well as alternatively temporarily disabling the integrated center of consciousness in each brain. For part of the process, both brains' centers of consciousness would optionally need to be simultaneously disabled (naturally as sleep, and artificially with technology support) to allow natural, enhanced with technology support, optimized information dissemination from the other brain into each brain. During the process, information from the second brain would be naturally, enhanced with technology support, optimally integrated with Mary-I's brain, and vice versa, resulting in Mary-I's being able to consciously sense and deliberate with memories in the second brain and sense and process input from the second body. The second brain would be able to do the same with memory in Mary-I's brain and input from Mary-I's body.

[0047] Mary-I and the other individual could be geographically located separately anywhere (albeit in the earlier incidences of implementation of the mechanism in this Patent Application they should be in proximity), and at the conclusion of the process of that optimal functional integration, Mary-I and the second human would each have a voluntary (i.e. it can be switched on and off at will), augmented cognitive ability primarily Solely (i.e. in the most part) using the physical resources of the other brain. The centers of consciousness of the two separate brains would also be able to at will operate as one or separately. At that stage, either Mary-I or the other individual, could be relocated to the other brain.

[0048] The applicant emphasizes that in this invention dual-directional transfer is more recommended than unidirectional, towards a higher degree of potency of the process.

[0000] Step 3—Relocate to Second Brain and Physically Disassociate from Original Brain

[Key Feasibility Controls Applied—(i.), (ii.), (iii.), (iv.), (v.). The notable inclusion of (iv.) is relevant for reasons of the reduction (by way of disassociation from the original brain (hence from the center of consciousness therein)) of the augmented, integrated, logical brain (hence of the augmented, integrated, logical center of consciousness) of Step 2] (Ref. “Key feasibility controls”)

[0049] The sequence of the two operations in this Step 3 surmised in the step title above is important—relocation at will happens first, physical disassociation with the original brain happens next.

[0050] With the two brains having already been functionally integrated in Step 2 towards the creation of one logical, augmented, integrated single center of consciousness (that will also have, to appropriate extents, retained awareness of and control on the separate original identities), it would be necessary here to get the two brains' centers of consciousness suitably collaborating towards confirming with Mary-I that she can acceptably sense an integrated consciousness using the centers of consciousness and memory in both the brains and input from both the bodies and then checking that the same responses are consciously made representing Mary-I from the second individual. Next, Mary-I would consciously (and otherwise, with external technology support) actively “relocate” in a highly focused, deliberated and conscious fashion to the augmented, integrated, logical center of consciousness and voluntarily (by focused deliberation or otherwise, with external technology support) disable (or render less relevant) her own brain's center of consciousness thereby gradually relinquishing control of self identity from her own brain and allowing self identity to be processed from the augmented, integrated, logical center of consciousness (which by then would essentially comprise of, in whole or in (typically the most) part, the logical center of consciousness of the second brain, and (typically) an additional consciousness component (that, as indicated elsewhere in this Patent Application, may be reduced or eliminated) originally present in neither of the two original centers of consciousness) such that when her original brain is then disassociated her consciousness (and hence by definition her self-identity) would all the while have remained active in the other brain, she becoming Mary-II-B. Implementing the process while conscious per the critical procedural preference stated above would render the process reasonably safe in the sense that Mary-I would definitively know that she has transferred to the second brain prior to her death.

Step 4—Repeat Steps 1 to 3 for Essential Immortality

[0051] Mary-II-B can repeat the three steps 1-3 at an appropriate time before the physical death of her new body. This cycle of 4 steps is continued, to render Mary-I effectively immortal.

Other Considerations

[0052] To be noted here is that memory/personality information in the sections of the brain that are not relevant to conscious cognition (e.g. breathing, swallowing, etc) will be given a lower priority for transfer. The reason for that is that while those components do have a minor contribution to self identity, that contribution is relatively minimal. Most of these lesser significant to self-identity inadequately cognitive body functions would be directly taken up by the host body's already existing capabilities.

Fair Scope of Invention

[0053] Without limiting itself to (i.e. irrespective of) any specific support hardware, this Patent Application covers the four-step process earlier detailed, even when more than two brains are involved. The latter is possible, per discussions in this Patent Application, if for example Mary-I chooses to link to multiple (and not just one) other brains towards forming an integrated brain with an integrated consciousness center, prior to delinking from them all into one brain (or—not recommended—multiple brains, towards an integrated, augmented center of consciousness) of her choice to form Mary-II-B.

[0054] In short, this Patent Application encompasses not only all morphs/variations/renditions/forms/flavors of the combination of the three steps (Step 1, Step 2 and Step 3) with and without Step 4—enumerated in the section “Specific steps in invention”—but also (all morphs/variations/renditions/forms/flavors) of the following core sequence of three steps Step A, Step B and Step C, with and without Step D (that together constitute an adequate, accurate superset to the steps in “Specific steps in invention”), in the premise of, but not limited by, the applicant's comprehensive logic, details, options and variations elaborated in the entirety of this Patent Application. As is self evident, all applications of existing or future technologies in the context of all morphs/variations/renditions/forms/flavors of the sequence of three steps—Step A, Step B and Step C—with and without Step D, are included in the scope of this Patent Application. Notably, Step B and Step C by themselves or together in any sequence, whether or not preceded by

Step A and succeeded by Step D are also included in the scope of this Patent Application. Step A by itself is covered in the Patent Application only to the extent that it is relevant to medically perpetual persistence of essential human life as detailed in this Patent Application, as well as to the form of connection outlined in (and therefore may be lawfully expanded or extrapolated on as being included in this Patent Application's scope) Step 1 of “Specific steps in invention”. Step A and elsewhere in this Patent Application and to the application of interbrain communicating technologies described in “Technology supported interbrain communication” and elsewhere in this Patent Application. In extension, of “Specific steps in invention” Step 2 and Step 3 by themselves or together in any sequence, whether or not preceded by Step 1 and succeeded by Step 4 are also included in the scope of this Patent Application. Step 1 by itself is covered only to the extent that it is relevant to medically perpetual persistence of essential human life as detailed in this Patent Application as well as to the form of connection outlined in (and therefore may be lawfully expanded or extrapolated on as being included in this Patent Application's scope) that Step 1 of “Specific steps in invention” and elsewhere in this Patent Application and to the application of interbrain communicating technologies described in “Technology supported interbrain communication” and elsewhere in this Patent Application. However the technologies themselves, to the extent not discussed in this Patent Application and to the extent not applied towards all morphs/variations/renditions/forms/flavors of one or more of the three steps below (Step A [except when Step A is excluded from the Patent Application's scope as described above]. Step B and Step C, in any sequence, with or without Step D) would be outside the scope of this Patent Application. Again, the novelty and hence the scope of this Patent Application is not limited to the application of the supporting technologies towards the steps below and (application) to the steps in “Specific steps in invention”, but importantly includes the steps themselves. The novelty of the steps is MORE significant than the novelty of the application of the technologies themselves towards manifesting those steps. However, the fact that the invention entails the use of technology as a necessary aspect of each of the four steps contributes to enabling the invention's lawful patentability.

[0000] A. Mary-I's brain is linked to one other brain, or multiple other brains.

[Key Feasibility Control Applied, Appropriately Extrapolated—(iii.)] (Ref. “Key Feasibility Controls”)

B. Mary-I learns (using a combination of (various levels of) conscious-, various levels of subconscious-, and (various levels of) unconscious-initiatives with technology support) to use other brain(s), towards forming one integrated, augmented brain (or a combination of communicating integrated, augmented brain systems) containing one integrated, augmented, logical center of consciousness (or a combination of communicating, integrated, augmented, logical centers of consciousness, only one of which would have authority over the set of participating brains in that particular augmented, integrated, logical center of consciousness, at any one time). Each integrated, augmented, logical center of consciousness would comprise of in whole or in (typically the most) part, the logical center of consciousness (hence include an appropriate fraction of the consciousness component therein of the associated brain) of each individual constituent brain, and (typically) an additional minor consciousness component (that may preferably be reduced or eliminated for the integrated, augmented consciousness to maintain acceptable fidelity to the logical integration of the original set of consciousnesses) originally associated with none of the constituent brains. Each integrated, augmented, logical center of consciousness will be physically located across one or up to all of the individual single original centers of consciousness in each constituent brains—preferably (for upcoming (per Step C) Mary-II-B's logistical convenience) in exactly one of the constituent brains' centers of consciousness—and only one integrated, augmented, logical center of consciousness may control a constituent brain at any one point of time, even though that brain may be part of multiple separate integrated, augmented, logical centers of consciousness. As part of that learning Mary-I would consciously, subconsciously and unconsciously adequately recognize herself (inclusive of all, most or an acceptable extent of her key original memories) using the (and each, when multiple) integrated, augmented, logical center(s) of consciousness—hence the logical center(s) of consciousness in the other brain(s). That recognition would alternatively be, at Mary-I's conscious/subconscious/unconscious initiative/will, using some/all the centers of consciousness (i.e. at will, including her original own and the other(s) and separately using only the other(s) and not her original own). As indicated at the top of "B", at the end of this step will be formed one integrated, augmented brain (or a combination of communicating integrated, augmented brain systems) including Mary-I's brain, containing one integrated, augmented, logical center of consciousness (or a combination of communicating, integrated, augmented, logical centers of consciousness, only one of which would have authority over the set of participating brains in that particular augmented, integrated, logical center of consciousness, at any one time).

[Key Feasibility Controls Applied, Appropriately Extrapolated—(i.), (ii.), (iii.), (v.)] (Ref. "Key Feasibility Controls")

C. Mary-I chooses a logical center of consciousness if multiple individual logical centers of consciousness have been created in step B., "relocates" to it, logically disassociates from Mary-I's original brain (i.e. from the original center of consciousness of Mary-I) (Note—while a physical disassociation from Mary-I's brain is not mandatory, that will typically ultimately follow), and therefore manifests Mary-II-B within that chosen logical center of consciousness. The logical center of consciousness would ideally be located physically in just one of those other (i.e. non-Mary-I) brains—hence in the center of consciousness therein that one brain—for enhanced logistical convenience of Mary-II-B (but could in principle be located in more than one of those brains as well, as long as they're logically linked forming one integrated, augmented, center of consciousness). At the and of that transfer Mary-I's brain will be logically, and in practice often physically, disassociated from the integrated, augmented, logical center of consciousness that Mary-II-B has relocated to.

[Key Feasibility Controls Applied, Appropriately Extrapolated—(i.), (ii.), (iii.), (iv.), (v.). The notable inclusion of (iv.) is relevant for reasons of the reduction (by way of disassociation from the original brain (hence from the center of consciousness therein)) of the augmented, integrated, logical brain (hence of the augmented, integrated, logical center of consciousness) of Step B] (Ref. "Key feasibility controls")

D. For essential immortality of Mary-I, Mary-II-B will repeat steps A, B and C at an appropriate time prior to the physical death of Mary-II-B's (new) body. The cycle of 4 steps is repeated for as long as Mary-I is wished to be kept alive.

[0055] To clarify scope, while the manifestation of Mary-II-B is complexly covered within the scope of this Patent Application, the manifestation of Mary-II-A in itself is not covered in the scope of this Patent Application as long the scope of this Patent Application detailed in the rest of this section ("Fair scope of invention") is otherwise rigorously applied—to rephrase, the use of morphs/variations/renditions/forms/flavors of the stated four-step process towards the creation of Mary-II-A is covered in this Patent Application's scope.

Proof of Feasibility/Tangibility/Concreteness/Originality/Innovation, Hence Patentability

[0056] The sections "Key feasibility controls" and "What is self identity and how is that relevant to perpetual persistence of life?" outline the primary bases of feasibility. Additional feasibility considerations are in the sections "Recommendations", "Deliberations & clarifications" and "Technology enabled interbrain communication". "Specific steps in invention" and "Fair Scope of invention" make explicit application of the bases of feasibility surmised in "Key feasibility controls".

[0057] The proof of tangibility is of course in the perpetual continuity of life this invention achieves.

[0058] The proof of concreteness is in the specific four steps listed in the sections “Fair Scope of invention” and “Specific steps in invention”.

[0059] The proof of originality and innovation is of course in the very fact that feasible, tangible and concrete perpetual persistence of essential human life constitutes this invention, because perpetual persistence of human life has never been possible yet in any other invention by humankind.

[0060] While the novelty of the overall four steps of the invention is substantially more significant than the novelty of the application of the technologies themselves as part of the invention towards manifesting those steps, the integration of such appropriate technologies as a necessary aspect of each of the four steps of the invention, therefore and otherwise rendering the overall invention original, innovative, feasible, tangible and concrete, contributes to enabling the invention's lawful patentability. Additional details on feasibility could be provided upon request—reflecting that it is appropriate to neither limit the applicable technologies nor immediately build a physical prototype because:

Many different technology options are currently feasible for this invention, with and/or without the relevant follow up insignificant (and/or optionally significant), time spanning, observation and analysis, whereby the immediate patentability of this invention remains entirely undiminished, and is in fact augmented, by such follow up—and other technical considerations.

A complete physical prototype would be feasible if sufficient funding, time and direct and/or at least indirect public will (for example, but not limited to, in terms of a commercial end user market for the invention) are confirmed.

The immediate building of a physical prototype is as unnecessary to affirming the validity (i.e. originality, novelty, feasibility, tangibility and concreteness)—and hence the patentability—of this invention as would be, for example, for any other entirely unrelated invention (not in the scope of this Patent Application) whose originality, novelty, feasibility, tangibility and concreteness are entirely self evident, yet building a physical prototype would require the availability of funds, time and/or at least indirect public will.

Recommendations

[0064] It is important to note that as part of the applicant's considerations on quick implementation feasibility the applicant emphasizes on the following—

Recommends that consciousness be preferably transferred across existing brains of reasonable maturity. Of course the more similar the second brain is to Mary-I's original brain (if largely “regular”), the better would the quality of Mary-II-B be—and if Mary-I's original brain is less than regular (e.g. from a congenital- or injury induced hardware shortcoming) then the target brain to transfer to should ideally be regular. Of course the younger the second individual would be, generally the better, in order to increase the likelihood of minimizing the frequency of such transfers (including, but not limited to, by delaying the onset of normal “old age” post transfer). If inter-brain communication is aggressively tuned per the direction outlined in this Patent Application, the applicant infers that the creation of Mary-II-B will begin being possible any time within 8 or 10 years.

Includes the possibility of rendering consciousness transfer across clones, which in principle would be the ideal form of consciousness transfer. That is because the technology to create clones is available today, and it would be supportive of this invention to create a young Mary-II-B when Mary-I has already reached a relatively senior age.
Strictly excludes fancy considerations like transferring to a computer. That is not practical simply

because the inherent hardware design of the modern day computer vastly reduces the likelihood of the hardware being able to sufficiently multi-process with extremely low consumption of energy to render the computer portable and otherwise feasible. In short, the modern day computer is completely counter to hosting cognition even remotely as optimally as human cognition in the human brain—the best modern day supercomputer does unacceptably more work than the human brain would for the same job.

Deliberations & Clarifications

[0068] Important considerations in this invention are the following—

a. The same brain and body resources cannot be set to be simultaneously controlled by two separate logical consciousness centers. At most only one logical center of consciousness can take control at any one time. In extension, there can at one point be only one (integrated) logical (i.e. constituent components not physically delinked) center of consciousness as far as self identity is concerned. Refer “f.” below.
b. It is not necessary for every bit of information in Mary-I's brain to be transferred to the second human. That is because human memory and personality are both plastic and are changeable. As long as a reasonable amount of information is transferred that would enable Mary-II-B to acceptably recognize herself, that would constitute a good start. Innate human cognitive capabilities would then naturally do the needful to attempt to build up a new memory bank and personality using that information. With the passage of time as newer and faster information transfer techniques are developed, Mary-II-B's brain (excluding prior information already in the second brain) would more closely represent Mary-I's brain at the time of transfer.

c. The technology to clone any human organ is already available today. Therefore, if the center of consciousness (namely the centromedian nucleus and allied components) for any human brain were cloned and connected in parallel to the same endpoints in the rest of that specific brain (namely sending nerve fibers to the cerebral cortex, putamen, caudate, collateral fibers etc. and receiving nerve fibers from the spinothalamic tract, cerebral cortex, superior colliculus, reticular formation, globus pallidus, vestibular nuclei etc.), would the sense of “I” be adequately realized in the cloned center of consciousness such that the two parallel centers of consciousness could operate in the following ways?
1. As one combined augmented logical center of consciousness.

2. As two separate logical centers of consciousness where each center remains aware of the other center and complete control of the resources (and hence of one's consciousness, and hence, by definition, of one's self identity) by any one center at one time is taken by voluntary joint consensus.

[0074] The applicant infers that the answer to both is “Yes”.

[0075] As an extension, “1,” would be possible differently if the cloned center of consciousness were not just connected at the ends with the original but entirely merged with the original.

d. If, in addition to the center of consciousness, the rest of the entire brain were cloned too, such that initially each component still remained functionally part of the corresponding original brain such that the entire brain functioned as a “super” brain with one consciousness, and then if the two sets of components were separated to form two separate exactly similar brains, would the original single sense of consciousnesses be copied in both brains and if so how would it be in relation to the original single sense of identity?

[0077] Obviously, with no physical connection between the two brains, the hitherto similar manifestations of the same consciousness would thenceforth develop into two distinct flavors of consciousnesses in separate ways from the point of separation. The original sense of self identity could remain in any one of the two brains, but never in both the physically disconnected brains at the same time. To rephrase, Mary-II-B can be manifested in at most one of the two physically disassociated brains.

e. Mary-I should select the individual to transfer to well in advance of her anticipated death, and effect transfer of all meaningful long term memory in advance. Following that, Mary-I should periodically transfer further long term memory since accumulated. Ideally this whole process should be undertaken with at least two geographically apart individuals to minimize the risk or not ultimately having any individual available to transfer to just prior to Mary-I's death.

f. Could Mary-I be transferred to multiple third party brains? The applicant infers that the answer is “NO” as far as Mary-II-B, but ‘yes’ in the context if Mary-II-A. There HAS to be at most one single logical (i.e. constituent physical components not delinked) center of consciousness where one can acceptably-self-identifiably transfer to at any one point of time. Therefore, while it is possible for multiple brains to function together as a whole (as earlier detailed), there HAS to be only one logical center of consciousness for them all as far as acceptable self-identification. That integrated logical center of consciousness doesn't have to necessarily physically be entirely in any one of the linked multiple brains, but suitably distributed across them all—non-functional individually but functional as a whole. Therefore when the physical link between the brains is broken—the actual transfer (towards Mary-II-B) would AT BEST be in only one brain—the other physically delinked brains can AT BEST have COPIES (towards Mary-II-A, that, as earlier elaborated, would not be acceptably-self-identifiable) of that original identity where SEPARATE, independent development would proceed from that point of physical disassociation. AT WORST, the transfer wouldn't happen at all, and the original individuals would just be left with new memories that they'd recognize as not theirs (since the memories would not involve them, but primarily Mary-I, and secondarily some of the other people in the set). What would NOT HAPPEN is Mary-II-B's manifestation in more than one separate brains.

g. Could, following a transfer, Mary-I separately sense herself being present in both her original brain and in the second brain that is no longer connected to her own still alive brain? This is an extension of sub-query “d.” and “f.” above, and the answer is “No”—she can be transferred as Mary-II-B to another brain while still alive, as long as she volunteers to let her own brain's center of consciousness give up control of her consciousness to the second brain's center of consciousness.

h. In the context of a brain that has been devoid of all forms of external input to it since inception, would that brain have medically wake and sleep cycles, and if so would the brain have dreams in those sleep cycles? Extending upon the behavior of a human baby in the womb, it can be reasonably presumed that the brain probably would have sleep and wakefulness cycles, simply because that property appears to be genetically so entrenched in the system that it would manifest itself regardless of input. As far as dreams—the applicant infers that an entirely-input-devoid brain does not logically appear to be capable of any cogitation because there would be no basic rules framework in the brain's memory database that can be used to cogitate with—and since cognition appears to be logically impossible, dreams in the way we know it appear to be impossible as well. In other words, there would potentially be no meaningful difference between that brain's state of wakefulness and sleep/dreams. However, this inference is not directly related to this invention.

Technology Enabled Interbrain Communication

[0082] The applicant infers that it is feasible to have two separate brains (learn to) communicate ((at least) initially with active conscious will, to enable the brains learn to recognize the signals and hence the communications mechanism) in a micro-focused electromagnetic communications environment of multiple simultaneous signals of the appropriate strengths and frequencies focused at equivalent brain components in the two brains, as briefly expounded in the following paragraph. Although neurotransmitters could potentially be used to render the process more potent, the applicant deems that essentially unnecessary given that the electromagnetic signals received would anyway enable the natural generation of the appropriate neurotransmitters as the brains deem necessary to process those signals. Essentially, the detected output signals from the relevant components of one brain would need to be appropriately modulated and micro-focused on the appropriate input components of the other brain. That modulated input would be in the form of ultra-low voltage signals at compatible frequencies and strengths (and duration for transfer effectiveness (because transfer will not always be real time, but suitably time lagged mandated by the complexity (i.e. relevant ranges of frequency and strength mapped to physiological zones) of the “sending” brain's emanated signals, the fuzzy logic feedback learning based, identification of the “receiving” brain's internal physiological locations, modulated receiving frequency and strength)). It needs be noted that each of the two brains would alternately be the sending and receiving brain, for purposes of familiarization of the data contents, initially towards the objective of creating the integrated brain system with one center of consciousness, then for Mary-I to transfer onto the other brain towards creating Mary-II-B (and both brains will have already previously agreed to this transfer so that transfer would typically not need to be consequent to a new decision after the creation of the integrated brain). For speedier and greater practical effectiveness, brain-physiologically-functionally meaningful ranges of signals detected in the “sending” brain should be modulated at meaningfully comparable strengths, frequencies and durations at the “receiving” brain at the latter's corresponding physiologically-functional reasonably equivalent micro locations, over electromagnetic waves at least at the “receiving” brain and preferably also detected as electromagnetic waves in the “sending” brain (since electromagnetic waves would enable optimizing (the process of) interbrain signal interactivity over a meaningfully variable range of modulated strengths, frequencies and relevant physiological locations at the “receiving” brain in the context of the counterparts of the “sending” brain). Extreme accuracy of physiological locations will not be important (only) at the commencement of communications, just reasonable micro-focus on output/input brain components, as signal attributes can subsequently be tuned from the feedback of the participating individuals as well as automatically directly from the neuronal responses at the receiving brain, and furthermore the brains would learn to recognize the signals and optimally adjust for the best sensing and interpretation of the signals. Operations research, numerical analysis and stochastic techniques, coupled with neural networks would optionally enable identifying the participant set specific fine tuned communication signal parameters, including, and of course not limited to, the component micro 3D coordinates internal to the corresponding brains. The logistical flexibility of using wireless electromagnetic waves at both the sending and receiving brains as elaborated in this section would enable the aforementioned computation premised search-and-find-for-optimality micro focus to be extended to if necessary the individual neurons, even to the level of the individual dendrite and axon (and allied) connections per neuron, but in the most part that would not be necessary because (a) there is sufficient neuronal redundancy of distribution of the same bit of information and (b) the equivalent location neuron counts across different brains would be substantially different so a super-micro-mapping would be inapplicable. The micro-focus process can even be expanded upon at the end (i.e. after appropriate focus maximization with electromagnetic devices) using atomic- and/or molecular particle based sensing devices, but that too would not be necessary in the most part. Search and find would essentially need to be targeted on the maximum feedback from participants and more importantly on the maximum automated neural responses at the receiving brain corresponding to the signal received from the output counterpart, at the sending brain, upon commencing the process at the approximate focused locations of known input/output counterparts, and honing in with the stated mathematically optimized techniques premised on the nature of non-optimized (only to reduce the search time—search without mathematical optimization would also work but would take longer, potentially infinitely longer in a few cases) searches until the maximal feedback from the participants and more importantly the maximal neuronal responses at the receiving brain is obtained that would indicate a successful link for that specific micro-component input output pair at the corresponding brains. Again, the data transfer needs preferably be in both directions (either simultaneously and/or alternately) so the sending brain receives real time feedback from the receiving brain and adjust suitably. Furthermore, and separately, and as indicated elsewhere in this Patent Application, from a brain learning and managing perspective, the data transfer needs preferably be in both directions (again either simultaneously and/or alternately).

[0083] As also indicated elsewhere in this Patent Application, as part of the connection process, the two linked brains are to be alternately (and sometimes jointly) rendered asleep or otherwise non-willed to allow each brain to learn to be aware of and function with the memory banks and consciousness components of the other brain.

[0084] While electrodes could be useful for physiological zone counterpart mapping at the brains, they aren't necessary and are not recommended for this invention, because of the need to participant-specific-variably-micro-“search”-and-“find” optimized input/output brain coordinates, which would be best possible with micro coordinate focused electromagnetic signals—that can (unlike with electrodes) be easily refocused anywhere—of the relevant frequencies, strengths and durations. Hyper fine tuned (per the above techniques) parallel connections of the consciousness- and memory bank relevant corresponding components (supported by the pertinent functional/communications accessories of course) in the two brains would be an additional consideration. Focus should primarily be on the regular communications channels internal to the brain (i.e. generally excluding the external input path components, for speed) so that key input information is laid down in a way that the receiving brain deems optimal, rather than using attempted “forced” communications via channels not ordinarily used by the human brain which could result in the information not being stored properly.

[0085] To the extent necessary, a chemical connection with neurotransmitters, as well as a direct, neuronal connection could and should also optionally be considered, as a catalyst to manifesting and optimizing inter-brain communication.

[0086] Although memory (and hence also the additional allied) data transfer is from a memory subcomponent buildup (i.e. bottom up) perspective (whereby the memory subcomponents are acquired with equal or more priority as/than are the higher memories that those subcomponents make), alternative consideration would be to allow the sending brain to consciously (and separately with altered, typically diminished, and at times raised levels of consciousness) “load” (i.e. become aware of to a degree of clarity that may be perceived by the (other) brain connected to this brain) relevant memories from its data bank that that brain deems relevant to the transfer and then enable only those memories to be transferred to the other brain. The advantage of this process would be that information would be relatively easily recognized by the receiving brain. The shortcoming would be that the process would be slow, often not include much of the memory (because of the sending brain's need to selectively load a memory first), and needs to be appropriately set up to not compromise or otherwise hinder creating the integrated, augmented, logical center of consciousness —i.e. the center of consciousness of the receiving brain must be suitably tuned to not simply consider the perceived (by it—the receiving brain) memory uploaded by (and at) the sending brain akin to just seeing new images and store that information (in it—the receiving brain) without, attempting to integrate with the sending brain.

[0087] Again, the key here for feasibility would be not to reinvent the wheel, but provide a supporting environment (that can be easily optimized per feedback from the two awake brains) conducive to enabling the brains' neurons to do what is natural to them—optimally integrate and communicate.

[0088] Any interbrain communication already patented, or otherwise not patentable, today is excluded from the scope of originality of this section, but such technologies are firmly denied the right to be applied to any aspect described as being within the scope of this Patent Application (Ref. “Fair scope of invention” and “Specific steps in invention”) without permission from this inventor.

[0089] Albeit already adequately clear above in this section appropriate additional technical elaborations on the above connection technologies may be provided with the non-Patent Application.

SPECIAL ADVANTAGES OF INVENTION

[0090] This approach is in principle a guarantee to perpetual continuity of life, provided of course that a transfer is done prior to Mary-I's death. Even terminal physical ailments in Mary-I would not be impediments to that continuity, as long as Mary-I's brain is still reasonably functional. In fact even mental illness too would be naturally corrected as long as the transfer is done to a brain without mental illness.

[0091] This invention pertains not to the speed of the process or emphasize on specific transfer mechanisms, but is the process itself. With time, as the transfer techniques speed up, the procedure can be applied for emergency circumstances when the Mary-I assesses a high likelihood of imminent death, for example when in an airplane that is about to crash, etc. In such scenarios, Mary-I would immediately wirelessly functionally integrate with the other brain located elsewhere outside the risk zone, rendering her brain and the new brain a single functional entity and “transfer” over.

[0092] The invention can subsequently be easily extended to primates or even animals of lower cognitive abilities.

What this Patent Application Does not Cover

[0093] This Patent Application does not cover the supporting technologies by themselves (that, when applied in the context of this Patent Application, would enable the brains to communicate) other than the supporting technologies that have been described in this Patent Application as being original—in particular in the section “Technology enabled interbrain communication”. Unless the applicant subsequently acquires patents on those technologies themselves, other inventors are free to develop and patent those supporting technologies to the extent permissible by law and use them for purposes other than that described in this Patent Application. However, all applications of current and/or future technology/-ies towards the following are obviously included within the lawful scope of this Patent Application: the scope of manifestation of perpetual persistence of human life as defined in the subsection “Fair scope of invention”. Although as earlier affirmed, the entirety of this Patent Application contains the applicant's own views (except of course the already medically affirmed components of consciousness of the brain comprising of the centromedian nucleus and the allied, and when implicitly or explicitly declared otherwise in this Patent Application) this Patent-Application also does not cover any aspect of the justification/validation/proof of this invention that might already have been previously patented by others in any other context, or is not patentable.

[0094] See “Fair scope of invention” for details on the scope of inclusion of just Step A (“Fair scope of invention”) or Step 1 (“Specific steps in invention”) by themselves in this Patent Application.

[0095] The coverage scope as detailed in “Fair scope of invention” will not be superseded by this section or any other section of this Patent Application.

[0096] Proof of enablement in principle of direct communication between human brains (termed “interbrain communication (IBC)”) towards unlimited extension to human lifespan

[0097] This section (extending for the remainder of the “DESCRIPTION OF INVENTION” of this patent application) (hereinafter referred to as “this section” or equivalent) presents the technical enablement of directly linking two human brains to establish viable direct communication between them, termed “interbrain communication (IBC)” by this inventor (and applicant), in the context of the original patent application filed by the same inventor (and applicant) on unlimited extension to human lifespan. The contents of this section elaborate on aspects of that original invention (of title

"Medically perpetual persistence of essential human life"), that (elaborations and aspects) are either expressly or deemed reasonably implicitly included in the original patent application, hence this section's contents are deemed appropriately protected by patent law towards that same prophetic invention as well as towards the same original patent application and therefore also towards this patent application with the original priority. The IBC mechanism and by and large the overall invention also extend to primates and other animals.

Keywords

[0098] IBC (interbrain communication), dendritic spines, corpus callosum, anterior commissure, event related potential (ERP), artificial synapses, stem cells, telencephalon, diencephalon, thalamus (in particular its centromedian nucleus), hippocampus, amygdala. Independent Component Analysis (ICA), (Multi-way/Kernel) Principal Component Analysis (PCA), Parallel Factor Analysis (PARFAC), signal decomposition, theta (4-7 Hz) and alpha (8-12 Hz) frequencies, neuron-to-glial-cell communication, protocadherin, CREB, NR3A NMDAR, entorhinal cortex, basal ganglia, precuneus, MEF2C, channelrhodopsins, synapse strengthening proteins, etc.

BACKGROUND

[0099] The original patent application for the invention that this section primarily aims at explaining the reasoned feasibility of the IBC portion of is PCT International Application No. PCT/IB2009/052355 filed with RO/IB on 3 Jun. 2009 (hereinafter referred to as "original patent application" or equivalent for the remainder of the "DESCRIPTION OF INVENTION" of this patent application (i.e. this section)) that incorporates by reference the entirety of USPTO Provisional Patent Application No. 61058253 filed on 3 Jun. 2008.

[0100] Not only would the invention enable human lifespan to be extended without limit for a healthy individual—it would in most cases even also enable the same for someone who is ordinarily deemed terminally ill or someone who has severe physical disability.

OBJECTIVE

[0101] This section highlights, and explains the reasoned feasibility of, some of the deliberated core technology approaches towards practically achieving IBC towards the stated perpetual persistence of human life objectives of the cited invention. For the reader's maximum comprehension of the most significant core aspects of the aforesaid IBC technologies, technical terms and non-essential technical details have been largely excluded from this section.

Governing Premises of Invention

[0102] As indicated in the original patent application, the invention's key objective is for perpetual persistence of human life to happen neither by attempting in futile to perpetually extend the life of the human body (which will never succeed) nor by attempting to merely create a biological "clone" of the entire human body or of the memory contents, as even theoretically exact biological clones would still be mere copies of, and not, the original and therefore (clones) would have the critical shortcoming of NOT being able to allow the original human deem the clone as herself/himself (i.e. the biological clone will NOT have the same, but will instead have a mere copy of, the sense of "I" that the original human will have) notwithstanding that that original human and others around that clone would correctly identify the clone as an accurate copy of that individual; therefore the original human would remain as mortal as ever with the aforementioned futile attempts at human lifespan extension regardless of whether or not her/his biological clone is created. Instead the invention aims to enable perpetual persistence of human life by transferring the brain's "self identity" (i.e. "consciousness" of the self, inclusive of consciousness-, subconscious- and unconscious awareness components) and allied essential and non-essential memory data (with that "self identity" and memory data, et al together constituting the same, not merely a copy of the, sense of “I”) to another brain, and in time from that second brain to yet another brain and so on in perpetuity. As indicated above, the phrase “consciousness” of the self purports to include not just conscious awareness of the self, but self awareness at the sub- and unconscious levels as well. One of the fundamental inferences, and therefore one among the core proofs/justifications/validations and governing premises and key feasibility controls, of/in the invention, is that any individual's specific self identity—therefore the specific “sense of I” originally belonging to that individual—could never be merely copied to be “active” while the original self identity is already still active, but can in principle be only transferred to (i.e. be rendered “active” in) only one logical center of consciousness (e.g. in one brain (or equivalent)). Another of the fundamental inferences of/in, and one of the key feasibility controls and governing premises of, the invention is that such “self identity” data is never tied to any specific brain (or other) hardware—in other words any brain is no more than a provisional holding/containing environment for, and is not itself (and is not uniquely necessary to hold/contain), the self identity of the individual who has that brain.

[0103] Another fundamental governing premise and a key feasibility control is that the entire original contents of any human brain are not necessary to uniquely and adequately define (i.e. uniquely identify the external manifestations of the functioning of) that brain—and therefore on extension (uniquely identify) the human who has that brain. Therefore, the entirety of a brain's conscious-, subconscious- and unconscious memory data would not need to be transferred to the brain of another human for adequately “transferring” the self identify of the particular human who has/had that (first) brain. Explained simply, just as when a human loses a limb (or surgically adds new limb(s), or grows massive quantities of new cells across the body as anyway naturally happens to extremely significant extents to every healthy human across the lifetime of that human) the remainder (or the partly or fully upgraded augmented rendition) of the human still remains uniquely and reasonably adequately identifiable (both to that specific individual's own self and to others) as being no other than that same original individual and appropriately functioning with/or without added prosthetics, and similarly just as when portions of a human's brain are lost to TBI (traumatic brain injury) or to surgery (or massive quantities of new brain cells are added to the brain as naturally happens to very significant extents to every healthy human brain across the lifetime of that brain) the remainder (or the updated partly or fully augmented rendition) of that human brain can still remain uniquely and reasonably adequately identifiable (both to that specific individual's own self and to others) as belonging to (i.e. manifesting) that same original individual and appropriately functioning without the individual's losing self identity (except in rare situations when conscious self identity is lost when the brain is too damaged, yet even then aspects of the sub-/unconscious identity and other functions of that brain often still remain sub-/unconsciously identifiable to the self, and consciously to others) with or without corrective/other alterations to the brain, the quality of the success of self identity transfer, hence the degree of effective perpetual persistence of life—i.e. the quality of effective biological immortality—of that specific human, would essentially be a function of the extent of the memories, primarily those related to conscious cognition and secondarily also including those that are not (namely sub- and unconscious memory data), defining that human that are transferred.

[0104] This premise is further justified by the fact that albeit every human's conscious and subconscious (and to relevant extents unconscious) memory contents are substantially different from the corresponding renditions 1 minute or 30 days or 1 year or 10-/20-/50 years ago by way of considerable alterations—primarily additive, secondarily modifying and/or subtractive—to the conscious-, subconscious- and unconscious memory content, each of the varying renditions of that same human's overall memory content essentially fully retains her/his identifying (both to that specific individual's own self and to others) uniqueness and to appropriate extents her/his adequacy of functioning.

[0105] Restating the above further, even when a huge volume of new memory content is added, and in most cases when much of the memory content is modified or lost, the person is able to consciously/subconsciously/unconsciously recognize herself/himself as being the same original person, as too do others around that person.

[0106] While the conscious aspects of memory (i.e. declarative memory (comprising of episodic and semantic memory)) would constitute the most prominent parameters uniquely defining any particular human's self identity, the sub- and unconscious memory components, learnt (i.e. procedural memory) and otherwise (i.e. genetically pre-existing sub-/unconscious “memories”, i.e. genetically pre-programmed neural attributes), not entirely or even at all related to conscious behavior, also contribute to uniquely defining that human's self identity—for example by way or the manner the human walks, laughs or otherwise interacts with society, other unique behavior or mannerisms of that individual, and even less significant, involuntary aspects as how that particular human breathes, etc. In other words, the identifying signature; of not just the brain's conscious and sub-/unconscious “memories” but even of the peripheral nervous system, including both its somatic and autonomic components—the latter's both parasympathetic and sympathetic categories—contribute to that human's self identity, although to a considerably lesser extent than the conscious memories. Therefore while IBC on conscious memory components would be the overwhelming core aspect of this invention, IBC on sub-/unconscious memories would also have a role, and to a very minor extent even IBC relevant to the peripheral nervous system.

[0107] It is important to note that the objectives of the IBC would include both to “transfer” (as in copy) memory data as well as to “transfer” (as in move) self identity. See the four steps listed in the original patent application (Ref. section “Specific steps in invention” on pages 10-16 of that original patent application) body for details.

[0108] For purposes of this invention, the areas of the brain that would be primarily, but not only, focused on towards enabling direct IBC with would be the memory and cognition sites in the telencephalon and diencephalon of the prosencephalon.

Feasibility of Invention

[0109] The original patent application cited in this section lists a total of five (5) key bases of feasibility of the invention (Ref. section “Key feasibility controls” on pages 8-10 of that, patent application). Those details are not comprehensively reiterated in this section; some of them have been (e.g. in section “Governing premises of invention” of this section, and in this section).

[0110] The feasibility of IBC itself has been covered at length in this section.

[0111] Albeit, owing to the complexity of the core innovations constituting the invention, the latter's proof of feasibility cannot be comprehensively expressed in simple terms (the entirety, not mere portions, of the original patent application requires the reader's meticulous, competent comprehension towards her/his comprehensive technical understanding of why and how the invention is feasible inclusive, and because of, its innovations), surmised below is the proof of the invention's feasibility in stripped down, simple, non-comprehensive terms constituting another legal proof of the invention's feasibility without detailing on the innovation aspects of the invention (other than naturally reflecting the cogently compelling innovation quantum extant in the following core approach itself towards enabling perpetual persistence of human life):

[0112] Brain neurons are already naturally highly versatile to essentially unlimited extents in terms of their ability to directly link up to (using newly generated intermediate neuronal pathways and/or existing neuronal pathways), and therefore communicate with, other already existing appropriate neurons in that brain, so there's no reason why, with the right, “reasonable” technology “aid” (i.e. with IBC), the neurons of one brain wouldn't naturally be able to directly link up and communicate with appropriate neurons of another brain. Such forms of neuronal communication are also already noted for example with transplanted organs/limbs.

[0113] Every healthy human brain naturally grows, at the appropriate time points in its lifetime (i.e. ranging from a very young age from before birth up to an elderly age), massive quantities of new neurons and integrate such neurons into that (regularly upgrading) brain causing almost every anatomical area of the brain to grow physically larger than it was before (as happens when the brain is still young) or (at least) be modified even when not physically larger (as happens both in young and older ages), allowing the original memory content and new memory content and (other) brain functions to continue to be appropriately integrated across that being-continually-physically-upgraded brain (with all earlier and newer memory data accessible as usual), and the brain still continues to have a single “logical” (as opposed to physical, as various physical locations in that brain are necessarily involved) center of consciousness—i.e. a well integrated single self identity continues to manifest (where the sub-components of self identity from the integrated memory data are all duly integrated, yet are still appropriately duly separately present for easy natural separate access willfully or otherwise). It is also scientifically well recognized that the extent and efficiency of the process of the overall memory encoding and retrieval and other capabilities of any brain can generally be substantially increased by deliberate natural effort/exercises in the brain. Therefore there's no reason why, with IBC and some deliberate natural effort/exercises in two brains, the same cannot happen with those two different brains—forming one integrated, single, “logical” brain (as opposed to one physical brain, since two physical brains are involved) with integrated memory data (i.e. combined memory data from the two brains, yet all memory data individually accessible post integration) and an integrated, single logical center of consciousness (and a well integrated single self identity formed of the two separate self identities (per the memory data) in the original two separate brains, yet those two separate component self-identities still appropriately duly separately present for easy natural separate access willfully or otherwise).

[0114] Because of the typically considerable multi-redundancy of both data storage and functionality within any healthy human brain, including the ability of the human brain to adjust to new data and develop functions anew when necessary, the healthy human brain is reasonably capable of appropriately adequately functioning even when portions of any of its functional/anatomical areas are naturally discarded or even suitably removed surgically. Therefore there's no reason why the integrated, single, “logical” brain of the above paragraph cannot have the first physical brain physically removed from it (by terminating the IBC following the conclusion of the action surmised in the above paragraph) with no loss to the integrated memory data and the integrated single self identity in the second brain. As indicated in the above paragraph the integrated single self identity and integrated memory data will already include memory and self identity from the first brain (integrated with, yet accessible separate from, the second brain's original memory and self identity), per this invention's objective.

[0115] The memory data contents of any healthy brain are being constantly increased (and to a certain extent modified or lost) across the lifetime of the brain; yet there is no loss to self identity (even if normal multiple (i.e. varied flavors of) “personalities” are present, which is a very common normal phenomenon for most humans). Therefore there's no reason why the integrated memory data in the second brain post-IBC-termination of the above paragraph would in any way compromise the integrated single self identity (duly composed of the two separate original self identities, each individually accessible at the integrated will of that integrated single self identity). As indicated above in the earlier two paragraphs the integrated single self identity in the second brain will have self identity from the first brain along with the self identity that the second brain originally had.

Feasibility of Interbrain Communication (IBC)

[0116] The feasibility of IBC is analyzed in this section under two sub-sections, one on the specific areas of the brain to focus IBC on, and the other on the specific technology particulars to use for such IBC. Some readers might prefer to review the IBC technology subsection before reviewing the subsection on brain areas.

Specific Areas of the Brain to Focus IBC On

[0117] The essential approach in the invention is a 1:1 component-mapped IBC simultaneously for all IBC-relevant components of count n in the two brains, where n<N, N being the count of all (i.e. inclusive of non-IBC-relevant) corresponding components in each of two brains. Additional considerations are to simultaneously, spanning all n components, have grouped m:m, m:M or M:m IBC, where m<M<n<N with the groups being functionally relevant, to allow greater efficiency yet ensuring that IBC data integrity would remain as good as in the 1:1 architecture because any irrelevant input signal (from the other brain) received over IBC at any member subcomponent of any group of m or M components would be automatically recognized and discarded by the brain.

[0118] The brain areas listed in this subsection include a majority, but not all, of the core areas to focus IBC on. Certain areas of the brain are mentioned more than once appropriate to their functional relevance to IBC. The areas are not listed in any particular sequence, other than by and large listing the IBC relevant components in the prosencephalon (constituted by the telencephalon and diencephalon, not necessarily covered in that order), mesencephalon and rhombencephalon in that order.

[0119] Before getting into IBC details per the above ordering it may be noted that the prefrontal cortex, amygdala, hippocampus, precuneus and other areas of the prosencephalon play significant roles in declarative memory; hence those regions would be highly relevant to IBC. The basal ganglia and the cerebellum have roles in procedural memory and hence are IBC relevant, albeit not to the extent of the brain components associated with declarative memory.

[0120] The neocortex (neopallium), hippocampus and amygdala of the telencephalon and the thalamus, hypothalamus, subthalamus and epithalamus of the diencephalon are among brain areas to be importantly considered for IBC. The neopallium subcomponents frontal cortex (specifically including and necessarily not limited to its prefrontal cortex), parietal cortex, anterior cingulate and parts of another component of the telencephalon—the basal ganglia—would be of high IBC significance.

[0121] Sections of the limbic system, namely the thalamus (including but not limited to the centromedian nucleus), amygdala, hippocampus, entorhinal cortex, limbic cortex, anterior thalamic nuclei, mamillary body, fornicate gyrus (inclusive of, but not limited to, its cingulate gyrus and the inferior parahippocampal gyrus), fornix, dentate gyrus, orbitofrontal cortex, and its other constituents would be among IBC priorities. It might be noted that there is not a universally accepted defined set of constituents of the limbic system.

[0122] The amygdala, for its role in modulating memory particularly but not limited to in the context of emotions, would have its IBC priority in this order: cortical nucleus, central nucleus, medial nucleus, basolateral nucleus.

[0123] Dentate gyrae, deemed part of the hippocampal formation, would be IBC relevant because neurogenesis occurs here allowing the formation of new memories, for example for the possible distinction between multiple memories of similar incidents.

[0124] The thalamus forms thalamo-cortico-thalamic circuits that are deemed critical to consciousness, and its role towards appropriate inter-brain memory data interchange with IBC towards individuality manifestation for perpetual persistence of human life would be vital. Among the most pertinent areas of the thalamus would be the centromedian nucleus (part of the intralaminar nucleus), also known as the centrum medianum (Cm-Pf/CM). The CM is known to have both excitatory (e.g. over acetylcholine) and inhibitory (e.g. over Gamma-Aminobutyric acid (GABA)) effect on the, corpus striatum. The medial dorsal nucleus is part of the thalamus and is connected to the limbic system and to the prefrontal cortex, and it has key roles in memory, abstract cognition, planning et al and will be part of IBC considerations.

[0125] The hippocampus is among the most important components relevant to memory formation, and would be a key IBC factor. It is believed that with the passage of time long term memories are formed outside the hippocampus. The key circuitry for the hippocampus involves receiving input from the relatively superficial layers (EC2, EC3) of the entorhinal cortex (EC) and sending output to the deeper layers of the EC. The cornus ammonis 3 (CA3) area of the hippocampus receives input from EC2 as well as from the dentate gyrus (DG, deemed part of the hippocampal formation as indicated previously in this section), while the cornus ammonis 1 (CA1) receives input from EC3 as well as from cornus ammonis 3 (CA3) (through the fibers of the “Schaffer collaterals”). The perforant pathway connects the entorhinal cortex to all the CA components of the hippocampus, as well as to both the subiculum and the dentate gyrus areas of the hippocampus. CA1 also receives input from the nucleus reuniens of the thalamus. Output from the CA1 goes to the deeper layers of the EC, either directly or via the subiculum (which is part of the hippocampus). This is represented in the circuit diagram in FIG. 3.

[0126] It is deemed that areas of the neopallium (a.k.a. neocortex/cerebral cortex/isocortex) and the hippocampus synchronize information and functioning in the theta frequency for various cognitive operations, including but not limited to for working memory activities.

[0127] Therefore the theta frequency would be an IBC synchronization basis for those components across the two brains.

[0128] As has been mentioned in greater detail in the IBC technology section of this section, this invention deems it meaningful to tap directly into the signals at inter-hemispheric neuronal pathways for IBC towards easier access into the respective hemispheres. Important among such IBC relevant inter-hemispheric neuronal connections are the corpus callosum, the anterior commissure and the hippocampal commissure (also known as the commissure of fornix).

[0129] The parahippocampal gyrus surrounds the hippocampus and is one among gyri that are part of the temporal lobe of the cerebral cortex (neopallium), and it is relevant to encoding and retrieving memory, hence pertinent to IBC. The parahippocampal cortex is a specific area combining the (medial) fusiform face area (FFA) and part of the (posterior) parahippocampal gyrus. The FFA complements the function of the PPA (which is part of the parahippocampal gyrus) in that the former is functional in the context of recognizing faces, while the latter is functional for scene recognition.

[0130] As with the entire above portion of this subsection, unless otherwise mentioned, all the components listed below in the remainder of this subsection would play a role in IBC.

[0131] Included in the (anterior) parahippocampal gyrus are both the entorhinal and perihinal cortices, both of which merit IBC. Forming the primary input to the hippocampus the entorhinal cortex (EC) (Brodmann areas 28 and 34) preprocesses the signals input to the hippocampus (for familiarity/recognition). Data connection with the EC is with the hippocampus, the prefrontal cortex, the perihineal cortex, etc.

[0132] The fornix of brain is a route for signals to the septal nuclei and mammillary bodies from the hippocampus, and deemed to be relevant to memory, hence is compatible to IBC considerations.

[0133] The mammillary bodies are material to IBC in that, among other functions, they route signals to the thalamus (via the mammillo-thalamic tract) from the hippocampus and amygdala, and are believed to have a role in recognition memory and smell memory.

[0134] The Papez circuit (FIG. 4)—a key circuit of the limbic system deemed significant to long term declarative memory encoding and (deemed by some) to control emotion—surmises some of the overall key connections of relevance to encoding memory, and hence its components are IBC pertinent.

[0135] The orbitofrontal cortex consists of Brodmann areas 11, 47 and 10 in humans, and is involved in decision making. It merits IBC considerations.

[0136] The medial temporal lobe (MTL) overall is thought to be associated with declarative memory, awareness and learning and would be relevant to IBC. Old memories are distinguished from new by the MTL regardless of consciousness state. Along the same lines, learning is facilitated by the MTL regardless of conscious awareness.

[0137] The basal ganglia is (are) highly germane to IBC, including but not limited to in the context of procedural memory. It is part of the telencephalon and is primarily comprised of the subthalamic nucleus, paleostriatum (a.k.a. globus pallidum), striatum (a.k.a. striate nucleus) and the substantia nigra. The caudate nucleus, which is part of the striatum, has learning and memory function. The putamen, which too is part of the striatum, has a role in various forms of learning, in particular but not limited to category learning, and although the exact functional specialization of the putamen is unknown the fact that it is connected to key brain areas and therefore and otherwise is deemed important to learning renders it notably IBC relevant to the project. The subthalamic nuclei, which are part of the basal ganglia, will also be specifically considered for IBC.

[0138] The primary motor cortex, which is part of the frontal lobe of the cerebral cortex, works along with the pre-motor cortex (Brodmann area 6) towards planning and making decisions. The supplementary motor cortex is relevant to memory and learning. The primary-, pre- and supplementary motor cortices will all be part of the IBC scope because the motor skills that they relate to would constitute part of the self identity signature.

[0139] The superior frontal gyrus—a major component of the cerebral cortex and an important IBC focus—has a key role in self awareness. Importantly, the inferior frontal gyrus is associated with verbal skills (Brodmann areas 44 and 45 constitute Broca's area for syntactic/semantic and phonological processing) and on selective decision making, hence it has IBC relevance vis-à-vis speech and decision signatures. While the superior- and inferior frontal gyri would be relatively important IBC candidates of the project, the middle frontal gyrus would be less so. The fusiform gyrus, by use of its FFA (Fusiform Face Area), would be a notable IBC candidate, for the reason of its playing an important role in recognizing faces and other objects.

[0140] Several among Brodmann areas associated with the temporal lobe would be appropriately assessed for IBC considerations. For example, BA20 (deemed to be associated with recognition memory), BA34 (also part of the entorhinal area), etc are relevant in that context.

[0141] The precuneus of the parietal lobe would have IBC relevance on account of its role in episodic memory, consciousness and self-awareness.

[0142] Among the other areas of the parietal lobe, the primary somatosensory cortex (S1, comprised of BA3-1) and the posterior parietal cortex would be low-to-moderately meaningful candidates for IBC on account of the individual identifying signatures they enable in the context of processing sensory and allied stimuli. The former is significant vis-à-vis sensing touch and other stimuli, and the latter enables planning by appropriately integrating motor and sensory functions. The postcentral gyms of the parietal lobe has functions that have some similarity to those of the posterior parietal gyrus, and would be a moderate IBC candidate for the project.

[0143] The insular cortex has several significant roles, including awareness of the body's internals, awareness of the self and control of emotions, control of motor functions, etc. and it would be an IBC candidate.

[0144] The cingulate cortex would be of IBC relevance, and appropriate of its segments—subgenual area 25 (BA25) (plays a role in the hippocampus pertinent to memory), anterior cingulate (essential to working memory), retrosplenial cortex (RSC) (relevant to memory)—would be given due IBC consideration. Both the parahippocampal place area (PPA) and the retrosplenial cortex are critical to spatial navigation, with the former focusing more on spatially interpreting the immediate local visual data while the latter on placing that data in the overall spatial context. The dorsal anterior cingulate cortex (ACC) effects cognition, while the ventral ACC is pertinent to emotion—so while both would be IBC candidates the former would be relatively more significant.

[0145] Brodmann areas 41, 42 and 22p (essentially comprising the primary auditory cortex and Wernicke's area) of the superior temporal gyrus would be IBC considered. The inferior- and middle temporal gyri would be relevant to some extent in as much as their visual processing (i.e. visual memory) signatures.

[0146] The mesocortical-, mesolimbic- and nigrostriatal dopamine pathways would be IBC contemplated.

[0147] The Nucleus Basalis of Meynert (NBM) of the basal forebrain is deemed relevant to attention, and hence would be material to IBC.

[0148] The temporal neocortex would be looked at for IBC, being where long term memory of the initial temporary memory is formed at the hippocampus.

[0149] The mesencephalon (mid brain)'s tectum has functions related to auditory (inferior colliculus of the tectum) and visual information processing (superior colliculus of the tectum), allowing it to carry information processing signatures (as different individuals would uniquely differently process the same visual/auditory information) that would uniquely identify a specific individual, rendering the mesencephalon moderately relevant to IBC. Much of the mesencephalon other than the tectum is the cerebral peduncle, which is often defined as being inclusive of the midbrain pretectum, tegmentum, and the crus cerebri.

[0150] The metencephalon and myelencephalon—of the rhombencephalon—would not be a priority for IBC but they would not be entirely excluded, because the sub- and un-conscious memory signatures they carry are unique to identifying specific humans. Of these two, the pons and cerebellum in the metencephalon have reasonable IBC relevance. Listed below are some of the functional areas where such signatures exist. The pons routes certain sensory data between the cerebellum and the cerebrum, and the pontine tegmentum of the pons has a role in REM sleep (and therefore in consciousness). The density of P-(ponto-geniculate-occipital)-waves in the pontine tegmentum increases following memory training activity, hence the inference that the P-waves are, and hence the pons is, relevant to learning. The parabrachial nucleus (PbN) has a role in taste sensation, including for signals received from the nucleus of the solitary tract (NTS). The pons also has a role in the synchrony between respiration and cardiac activity characteristics, thereby indirectly constituting one among brain centers associated with involuntary identifying signatures pertinent to IBC.

[0151] The cerebellum carries memory signatures by virtue of its important role in procedural memory, hence is relevant to IBC, in that it, among others, contributes to motor control with perception of sensory data, by enabling a coordinated integration of data exchange between the motor cortex of the cerebrum and spinocerebellar tract. The cerebellum in particular the neocerebellum—also has cognitive functions including but not limited to attention, of some IBC pertinence.

IBC Technology

[0152] i. Core Approach

[0153] For purposes of IBC quality and efficiency, every effort would be taken to refrain from reinventing "the wheel" from ground up, but rather by letting the brains maximally naturally communicate and acquire data content by themselves from each other in a signaling technology environment.

[0154] IBC would be an optimized functional and physical (i.e. anatomical) integrative process. In other words, IBC will be undertaken based primarily on anatomically equivalent locations of the two brains, the selection of which (locations) would be suitably optimized or modified based on functional equivalence, as precise functional equivalence might not always be identifiable by only anatomical or only functional equivalence alone. Towards that integrative process, to identify the approximate functionally equivalent locations, the two brains would be subject to a very wide range of categories of external stimuli (e.g. static and video images, language- and non-language audio and video (examples of language related video would be written text, video of people speaking, visually symbolic language), simple through complex logic processing scenarios that would evoke both regular-data-memory and logical-ability-(i.e. unique logic signature)-memory, olfactory input, tactile input (including but not limited to when combined with language), other memory evoking and allied memory relevant external input, etc) and internal stimuli (i.e. primarily electrical and electromagnetic (and optionally biochemical) stimuli applied internally directly into locations of anatomical relevance (including but not limited to information already publicly known on elaborate input/output sites of various neuronal circuits in the human brain) coupled with the aforementioned earlier-stage location conclusions consequent to the external stimuli) and the corresponding integrated locations and the respective brainwave frequencies would be noted. Those integrated locations in the two brains would then be identified with increasing accuracy in several stages by iterating the above process multiple times. Then IBC would be established between the two brains at those locations at (or otherwise compatible/synchronized to) the appropriate wave frequencies (including but not limited to in synchronized theta (4-7 Hz) and alpha (8-12 Hz) frequency ranges, given that those frequencies are deemed highly relevant to memory encoding and retrieval), strengths and durations—including but not limited to as a variable sequence of "signal bursts" of electromagnetic and/or electrical signals, while noting that IBC would (also) be appropriately directed to the respective input/output neural circuit areas—i.e. the output of a component of one brain fed to the input of the equivalent component in the other brain (instead of and/or in parallel addition to naturally feeding that output to the equivalent component in the same brain itself as well) and vice versa. The beta (12-30 Hz) and gamma (>30 Hz) frequencies would also be used for IBC, both when those are the base frequencies of the corresponding brainwaves at those locations as well as otherwise for augmenting IBC efficiency and quality. The categories of synchronizing the IBC signal with the brains that would be considered would be in-phase synchronization where there would he no phase shift and the frequencies match, out-of-phase synchronization where there would be a phase shift that could be greater than zero and less than half of the phase, anti-phase synchronization where the frequencies would be the same but there would be a half-phase shift, only-frequency-synchronization where the phases could be anything but the frequencies match, partial synchronization where in a large group of neurons some (typically the majority) would operate in synchrony but the rest wouldn't and the whole group would still maintain the overall synchrony, coincidental synchronization where there would be no uniform frequency or phase but nevertheless the probability would remain high that specific events (e.g. overall group of maximum or minimum spikes, etc) of the operations would match the corresponding events of the other, virtual modulated synchronization where the frequencies would be in integral multiples and therefore in a virtual phase. The reason for the need to consider all the above frequencies and phases is that two brains will not necessarily operate in the exact same frequencies and phases even at the earlier mentioned considerably precisely identified functionally equivalent sites: hence optimal frequency-phase-intensity-duration combination(s) corresponding to various functionally equivalent sites across the two brains would need to be identified specific to those two brains.

[0155] As mentioned above, external stimulus alone would not be adequate to evoking a sufficiently large domain of memory. The reason for that is that large chunks of memory would not have been originally created based on external stimulus alone, because much of such memory would have been formed consequent to logically variably internally processing (often involving a huge array and layers of internal logical processing and memory accesses) complex-external-input with already existing internal conscious-, subconscious- and unconscious memory data, hence such memory couldn't ordinarily be invoked by external input alone. Another reason for the need for direct internally applied memory retrieval triggers is that even for memories that have been formed primarily (Note: ordinarily it cannot be only) based on external input alone it would not be always practicable to select, all possible relevant combinations of external input as memory retrieval triggers to retrieve those memories, simply because such external input combination possibilities are too huge and too varied for different people. Accordingly, some of the memory would need to be accessed by direct internal stimulus to (i.e. internal signaling at—typically but not always necessarily electrical or electromagnetic) specific functional locations in the brain itself.

[0156] The synchrony in the partial and coincidental synchronization categories, among others, would be determined specifics of with appropriate numerical analysis, Fourier transform, and other processing.

[0157] Neuronal synchronization between the two brains would be across a massive count of neurons in each at the same time, over artificial chemical and/or electrical “synapses” located between each end of the virtual electromagnetic and/or electrical (and/or chemical) communications (for IBC) channel and the group of neurons at the two brains. All that would essentially be necessary, with relative technical ease, is to electrically detect the real (i.e. neuronal) action potential at the final (group of) neuron(s) in the pre-synaptic end(s) in one brain at the point it is connected to one (outbound) end of the IBC channel and transmit that electrical voltage—not at all necessarily at the neuron-typical +70 mV but at an appropriate (other) voltage—signal to the artificial synapse(s) at the other (inbound) end of the IBC channel connecting the other brain, which would result in the artificial synapse(s) at that inbound end of the IBC channel releasing the appropriate neurotransmitters (for an artificial chemical synapse) causing the triggering of, or simply electrically (for an artificial electrical synapse) directly triggering, an action potential in the first (group of) neuron(s) connected to the IBC channel at that receiving end, which should result in the natural chemical and/or electrical synaptic communication down the IBC link from one brain to the other, and back in a similar process.

[0158] These artificial synapses would be created to function at the appropriate oscillation frequencies pertinent to the categories of the pre- and post-synaptic neurons in the IBC link. Artificial synapses would be complimented by appropriate natural synapses that would (naturally) develop during IBC. It is to be noted that in the context of IBC these natural synapses are those that newly develop between neurons at either of the two brains to facilitate IBC per the brains' natural tendency to transfer, receive and assimilate information. While largely, other than the artificial and natural long-/short term synapses, the remainder of the two brains at the two ends would not need to be physiologically modified too much, some IBC effectiveness- and efficiency enhancing techniques, in part listed below in the remainder of this section, would be considered.

[0159] The corpus callosum is deemed in this invention an optional and/or complementing location for IBC connections. The reason for that is that because the corpus callosum already appropriately reaches into the depths of the two hemispheres of each brain, accessing those hemispherical depths would be appropriately relatively easier by directly accessing the corpus callosum itself. The specific connection points on the corpus callosum to enable IBC at would be identified in a mechanism using external and internal input to the two brains and determining which neuronal areas of the corpus callosum activate and integrating that information and the corpus callosum's already known anatomical (including circuitry) information with the corresponding activation and anatomical information for the remainder of the brain. That overall mechanism would be similar to that for identifying IBC connection points in the remainder of the brain as described in this section.

[0160] The anterior commissure which links the two cerebral hemispheres, albeit to an overall extent considerably lower than that for the corpus callosum, would be another area to focus IBC at, with proceedings as with the corpus callosum. Focus on the anterior commissure would be primarily, but not limited to, in the context of the temporal lobes and the amygdala pair, with those being among the primary brain components relevant to IBC that they connect across the two hemispheres.

[0161] In a manner similar to that for the corpus callosum and the anterior commissure, the hippocampal commissure (a.k.a. commissure of fornix) is important in as much as the hippocampus, because it in effect connects the hippocampus across the two hemispheres.

[0162] For IBC between equivalent components in the two brains it would not be necessary for those equivalent corresponding components to be linked in entirety or even to a highly major extent. When the entirety of two equivalent components in the two brains are not directly linked, the communication bandwidth available to the aforementioned directly linked subset of components would be used by the entirety of those equivalent components to communicate with, wherein data in the non-linked portions of the equivalent components of the brains would pass through the linked portions. In fact extreme accuracy in identifying IBC-relevant equivalent components/locations in the brains would not be necessary—reasonable accuracy would suffice—the equivalent components of each brain would know to filter in and filter out relevant and irrelevant signals from the corresponding equivalent and non-equivalent sections respectively of the other brain towards IBC. In fact irrelevant signals exchanged between even equivalent components across the brains would be similarly naturally discarded. However, the efficiency and to a certain extent the integrity (i.e. inclusive of quality) of information transferred (i.e. the extent to which relevant data is not excluded from transfer, and corruption is minimized of pre- and/or post-transferred data) over IBC would be increased with greater accuracy in connecting equivalent locations. A communicating “band” of reasonably high bandwidth, typically using an appropriately large count of virtual synapses, between reasonably equivalent brain components should be sufficient for IBC. Data would be exchanged across those bands between the equivalent areas of the two brains, somewhat akin to, but less extensively than, how the corpus callosum assists the two hemispheres of a brain to communicate. Just as any healthy brain continually naturally learns how to optimally use the corpus callosum depending on the content and other circumstances of the inter-hemispheric data transfer, the two brains linked for IBC would also naturally learn—with the appropriate technology assistance in the directions outlined in this section and in the original patent application—how to optimize the use of that IBC channel. In other words, IBC would happen, albeit inefficiently arid inadequately, towards the invention's objective of perpetual persistence of human Life, even with a relatively rudimentary IBC communications channel. Yet the more advanced the IBC mechanism per the directions outlined in this section and in the original patent application, the more efficient and adequate IBC would be towards the invention's objective of perpetual persistence of human life. The novelty/tangibility/etc—hence the patentability—of the invention is not only in the technology of the IBC mechanism towards that objective, but also significantly in the very fact that perpetual persistence of human life can at all be plausibly feasibly attained with IBC regardless of howsoever rudimentary (i.e. nevertheless always constituting the invention's use of the technology “tool” IBC) or sophisticated that IBC mechanism is.

[0163] Illustratively expanding with an example on the point of patent law on the logic of patentability of any invention, an ordinary nail in itself is not novel/tangible/etc as an invention—hence not patentable—any longer, but even if that ordinary nail with nothing else could be innovatively used for any purpose that newly achieves an extraordinarily significant, meaningful human objective even if a significant quantity of natural human biology constitutes a major proportion (hypothetically, even if as high as or higher than 99.99% as long as that proportion is less than 100%) of the overall technology process of attaining that objective, the use of that simple nail to at all enable that objective would constitute a patentable invention.

[0164] Various categories of event related potential (ERP)—namely potentials measured in the brains consequent to perception, cognition et al (as part of the earlier discussed overall process of external and internal input towards determining equivalent locations in the two brains for IBC)—would be used to identify the IBC relevant functionally equivalent locations in the two brains. Such ERPs would include, but wouldn't be limited to, N100, N400, P300 (P3), SPS (P600), ELAN (early left anterior negativity), late positive potential (LPP), etc. LPP is deemed relevant in the context of managing emotions, and is therefore deemed pertinent in the emotional memory signature transfer context of IBC. ERP P200 (P2) is deemed significant to the process of intent, and therefore and otherwise in memory. N270, N430 are deemed pertinent to conflict identification and processing. P3a and P3b are cognitively important in that while the former is associated with setting attention to something of adequate newness the latter occurs when unlikely events related to the task already being processed occurs.

[0165] Since EEGs contain information from several ERPs and other signals that are superimposed, thereby muffling the independent ERPs, it would be necessary to suitably process the EEGs with Independent Component Analysis (ICA), (Multi-way/Kernel) Principal Component Analysis (PCA) (including the Karhunen-Loève theorem rendition). Parallel Factor Analysis (PARFAC) a.k.a. Canonical Decomposition, Tucker Decomposition, Adomain Decomposition Method (ADM) for solving partial and ordinary non-linear differential equations using non-numerical techniques. Domain Decomposition Methods (DDM), Cholesky Decomposition, Largest Lyapunov Exponent (LLE), Hurst Exponent, Higher Order Spectra (HOS), et al.

[0000] ii. Optimization

[0166] Signal enhancing techniques need be suitably applied to render IBC faster and more adequate. Techniques surmised below would be among those that would be considered towards that objective.

[0167] Embryonic and adult stem cells as well as progenitor cells enabling the growth of new neurons would enhance IBC connectivity.

[0168] The CREB (cAMP response element binding) protein, deemed relevant in the formation of long term memories, would be assessed for optimized use at both the sending and receiving brains in the project. The memory augmenting effect of pregnenolone sulfate injected into the limbic system would be a factor considered towards expediting IBC. The memory consolidation effect of down-regulating NR3A NMDAR(NMDA (N-Methyl-D-Aspartate) receptor)s would be assessed, in particular, but not limited to, because it is understood that NR3A—a type of NMDAR—causes resistance to the formation of long term memories by way of reducing synaptic plasticity, (reducing) synaptic counts and (reducing) synaptic densities. PolyADP-ribosylation would be looked at in terms of maximizing long term memory formation. The interaction between NMDA receptors and D1 receptors would also be studied in the context of long term memory formation. Also would be assessed the effect (on long term memory) of the induction of AMPA receptors into synapses. Further assessment would be on the relevance (to working memory) of hippocampus dependent, configuration-relational (CR) synchrony in the thereabouts of the theta frequency across the temporal and occipital lobes and non-CR (non-hippocampal-dependent) maintenance across the parietal and frontal lobes, and the effect that alpha oscillations have on LTP. The effect of dopamine on LTP would also be considered. The effect of CAM kinase II on hippocampal LTP would be assessed. It is deemed that theta rhythms and interactions between theta and alpha rhythms are critical to encoding and recalling memory. Therefore substantial focus would be on theta and alpha synchronization for optimized IBC.

[0169] The significance of the MEF2C (MADS box transcription enhancer factor 2, polypeptide C a.k.a. Myocyte-specific enhancer factor 2C) protein to learning in the context of IBC would be investigated. In particular, the deemed reduction of memory (and therefore learning) abilities in specific areas of the brain, including but not limited to the hippocampus, (despite a possible consequent) associated increase in the synaptic densities, by under-expressing (i.e. reducing) MEF2C would be looked into.

[0170] Dendritic spines are deemed to be extremely significant to memory. In part because they're based on actin, they are highly plastic—i.e. they change their shape and size (and count) quickly, in particular the former (i.e. shape) which can change in seconds. The key types of receptors that dendritic spines express are receptors for glutamate and receptors for BDNF (Brain-derived Neurotrophic Factor). Examples of glutamate receptors are NMDAR, AMPAR, etc. Dendritic spines are deemed to be highly significant to cognition and short term memory as well, not just long term memory. Accordingly, a brain's ability to communicate effectively and fast would be directly dependent on the efficacy of its use of dendritic spines. The efficiency (i.e. speed) and extent of IBC would be significantly a function of the optimal production and use of dendritic spines in both brains (Note: not necessarily only the use of existing dendritic spines, but the use of dendritic spines specifically created to enable IBC be more efficient and effective).

[0171] The role of specific neuropeptides towards augmented neuronal interconnectivity would be analyzed, including but not limited to

Galanin: Of the three receptor classes GALR1, GALR2 and GALR3 (all of the G Protein Coupled Receptor (GPCR) class), significant would be GALR3 which is deemed relevant to memory and cognition. Galanin coexists with the neurotransmitter norepinephrine.
Neuropeptide Y: This neuropeptide coexists with the neurotransmitter norepinephrine (noradrenalin), GABA, epinephrine (adrenalin), and it is deemed to play a role in memory.
Substance P: This coexists with the neurotransmitters acetylcholine and serotonin (5-Hydroxytryptamine). It is specifically associated with pain reception. Artificially induced pain, at various locations, to various degrees and for varying durations, would be considered as an IBC enhancing factor for this project.

[0175] As indicated earlier in this section, the optimal production and use of dendritic spines would be critical to optimal IBC, so that huge volumes of memory (and related) data are transferred fast and without compromising the integrity of that data. Of high relevance in this context are the spine apparatus (endoplasmic reticulum) found inside some dendritic spines and the synaptopodin protein that constitutes an important part of the spinal apparatus. The factors that affect the morphology/morphogenesis of dendritic spines would be suitably used towards the production and use of dendritic spines for IBC. Such factors include, but aren't limited to, receptors, proteins for scaffolding, cytoplasmic kinases, enzymes, special proteins and chemicals, and electrical, magnetic and other stimulants, et al. For example, in addition to the AMPA receptor, NMDA receptor etc the SIGMA1 receptor (present at the endoplasmic reticulum) that encodes calcium signaling is deemed to be relevant to dendritic spine creation; enzymes, amino acids and tumor suppressor proteins like Scribble modulates the expression of dendritic spines; melatonin affects spine density; the GluN class (including but not necessarily limited to the GluN2B class) of NMDA receptors are deemed to be highly relevant to affecting dendritic spines in the hippocampus and cortex and thereby affect learning—optimally increasing GluN2B for example could augment IBC efficiency; protein kinase (a.k.a. phosphotransferase, which are enzyme(s) that function to transfer phosphate group(s)) that rely on Calmodulin (calcium binding protein) are also deemed important for dendritic spines in the context learning and therefore to IBC; etc. The effect of three of four classes of the oligopeptide angiotensin—namely classes II, III and IV—would be looked into in as much as enhancing adequate growth of dendritic spines and therefore of the efficacy of IBC. The extent to which the

ABI family of genes is able to affect actin polymerization and therefore (its receptors) affect dendritic spine formation would be a consideration in the project. Estrogen would be looked into in as much as its ability to optimize the morphology of dendritic spines, and therefore its use in IBC.

[0176] The molecular mechanism of storing memory would be appropriately IBC relevant. An overall mechanism of interest is the strengthening of synapses by creating proteins of the likes of Lypla, Cam Kinase, et al. The creation of those proteins happens by the relevant RNA that is otherwise blocked (from creating those proteins) with wrapping proteins, which are degenerated or broken down when new signals arrive freeing up the RNA to create the strengthening proteins. The use of this and allied mechanisms would improve IBC.

[0177] The absence of the chloride channel CIC-2 in nerve cells has been found to make them more excitable, hence in principle more capable of either transmitting or inhibiting information (the latter when such neurons are “inhibitory”), rendering that a possible means of controlling IBC.

[0178] The extent of glutamate released and reabsorbed (post signaling) would be a factor to be considered on how effectively neurons communicate with each other in the IBC context.

[0179] Advanced non-rigid ultra-thin electrodes in the 100 to 500 micrometer thickness range that are better able to mould to the human brain and transmit information much better than common rigid electrodes have already been developed, and these would if necessary assist in IBC.

[0180] Special DNA segments, called “enhancer regions”, are known to cause the release of specific RNA called “enhancer RNA” (eRNA) to release proteins that would augment the creation of synapses across neurons post stimulation, thereby enabling learning, making this of relevance to enhancing IBC.

[0181] The significance of “mirror neurons” that fire both when a human performs a task and the human watches another human perform a task, would be considered in the IBC context. The limbic striatum has been determined to be significant to implicit learning, and hence would be given due focus vis-à-vis IBC.

[0182] The effects of the hunger hormone ghrelin, produced in the stomach and pancreas, on memory and learning (by influencing the hippocampus) is of some relevance to IBC. Ghrelin is known to augment dendritic spine formation in the hippocampus and (thereby and/or otherwise) affect long term potentiation (LTP). IBC learning could be expedited and rendered more effective with the optimal administration of ghrelin.

[0183] The effect of neuron-to-glial-cell communication is pertinent, and would be specifically analyzed, in the context of enhancing neuron-to-neuron communication from the IBC perspective. The mechanisms of such neuron-to-glial-cell communication would include but not be limited to the neuron's synaptic and non-synaptic releases of specialized signaling chemicals, as well as other chemicals (e.g. neurotransmitters, ions, etc released into the glia) that ultimately boost neuron-to-neuron communication. Of particular interest would include, but not be limited to, the use of the calcium ions in the 3-way communication between glial cells and post- and pre-synaptic neurons. The glial cells of the greatest significance in this context are the oligodendrocytes and astrocytes of the CNS. Astrocytes are known to be able to regulate synaptic plasticity, not only as small groups on a single synapse but as larger communicating groups of astrocytes that combined affect a network of neurons. Astrocytes are known to be able to generate Ca<2+> signaling in response to neuronal activation, and its activity can be mediated by suitable agonists and antagonists, among others, thereby enabling an element of synaptic transmission control for use in IBC. Of secondary significance would be the ependymal cells and radial glia of the CNS. Schwann cells of the PNS, and to some extent even the role of microglia would be of some significance. Of added pertinence would be the role of P2X- and P2Y purinoceptors in the communication between glial and neuron cells using nucleotides, where gliotransmitter ATP plays a role. In addition, of interest would be determining if ephrin ligands and eph receptors could be optimally utilized towards neuron-glia communication, for enhancing IBC.

[0184] Fluorescence Resonance Energy Transfer (FRET) and/or allied technologies would be considered for IBC towards live observation of chemical synapse operation where necessary.

[0185] Protocadherin gamma-C3 (PCDHGC3), Protocadherin gamma-A11 (PCDHGA11), Protocadherin gamma-B7 (PCDHGB7), Protocadherin gamma-A12 (PCDHGA12), Protocadherin beta-13 (PCDHB13). Protocadherin beta-9 (PCDHB9), Protocadherin beta-16 (PCDHB16). Protocadherin beta-11 (PCDHB11), Protocadherin beta-14 (PCDHB14), Protocadherin beta-10 (PCDHB10). Protocadherin beta-3 (PCDHB3), Protocadherin beta-2 (PCDHB2), Protocadherin beta-4 (PCDHB4), Protocadherin beta-15 (PCDHB15). Protocadherin beta-7 (PCDHB7), Protocadherin beta-12 (PCDHB12), Protocadherin beta-5 (PCDHB5) would be investigated for relevance to neuron-to-neuron communication for IBC.

[0186] The effect of L-serine and other amino acids on aspects of neuronal growth, hence neuronal communication, would be IBC pertinent.

[0187] The use of light sensitive ion channels called Channelrhodopsins (Chr) towards selectively switching off areas of the brain as part of discerning activation for data transmission would be looked into in the IBC context. ChR2 could be among the more promising in that context, with the other options being ChR1 and VChR1—all of them being sensitive to the cations K<+>, Na<+>, H<+ and Ca><++>. Similarly haldosporin (NpHR) is a light sensitive ion channel that is sensitive to only anion (i.e. negative) chloride ions. ChR2 is sensitive to blue light (maximum absorption at wavelength 480 nm), while VChR1 is sensitive to yellow and could potentially trigger neurons around 580 nm. The use of the Arch and Mac genes, to switch off neurons when exposed to yellow and blue lights respectively, is another effective option, whereby those genes could be loaded onto viruses and inserted into neurons without affecting their operations, and when those neurons are exposed to blue or yellow light energy producing proteins in the cells are inhibited, resulting in the overall temporary deactivation of the neuron, constituting an IBC managing mechanism.

The Reversibility and Multi-Candidature Capabilities of Self Identity Transfer

[0188] With the feasibility of IBC already logically established across the above and earlier sections of this section, this section is not directly on IBC's feasibility but instead on some additional highly significant features of the invention, in the context of IBC.

[0189] Here's the gist, followed by summary elaborations:

[0190] Self identity transfer would be reversible, as long as the first human's body is still alive. That reversibility would be possible both at the end of Step 2 (when the self identity of the first human would be provisionally present in both brains (i.e. when the entire "transfer" of self identity (i.e. rendering self identity present in the second brain along with in the first brain and then removing it from the first brain) will have yet not happened, only "transfer" in the sense of its provisional presence in both brains will have happened)) or if elected at the end of Step 3 (when the self identity of the first human would be present in the second brain only).

[0191] The memory data that would be copied to the second brain as part, of Step 2 could be separately copied to the brains of multiple people as a separate set of Steps 1 & 2 for each, without undertaking Step 3 for any of them. The first person's self identity would remain not fully transferred (i.e. not rendered first present in the second brain along with in the first brain and then removed from the first brain) until Step 3 is completed with any one of them, so there'd be no loss of self identity from the first brain regardless of undertaking Step 2 for several different memory-recipient brains. Because Step 3 wouldn't mandatorily need to be undertaken immediately after Step 2, this would enable a choice of candidates to transfer to over Step 3 at the later time when the decision to transfer self identity over Step 3 is taken. That choice would be meaningful because external circumstances might render some of the memory recipient brains (i.e. those for which Step 1 and Step 2 will have been done) subsequently unavailable/unsuitable when Step 3 is decided.

[0192] As may be expressly inferred from the IBC details in this section, the actual IBC link would not need to be over physical wires, and could be entirely over wireless if so chosen.

[0193] It may be importantly noted that IBC proceedings in the invention would first be undertaken to comprehensively complete memory transfer activities (i.e. undertaken primarily as part of Step 2 of the four steps of the invention)—a process that would take time and therefore would need to be commenced adequately in advance of the actual physical body-death of the first human and (as an added procedural bonus) wouldn't require continuous IBC connectivity (i.e. it could be done in several separate sequential IBC sessions/phases) since memory data once transferred and stored in the second brain wouldn't ordinarily need to be retransferred—and only the core self-identity “transfer” (i.e. Step 3 of the invention) (that would not necessitate much memory data (re)transfer, optionally other than for some new latest and/or earlier memory data if so elected) would be left as the final, separate, IBC activity to be undertaken within a short span of time typically not long before the actual physical body-death of the first human. Because this step would be separate, there would be no need for the two human brains to remain IBC (re)connected until just before the point of that quick self identify transfer, thereby allowing the humans complete freedom to go about their own separate lives following conclusion of the memory data transfer of Step 2, until just before the decision is taken for self identity to be transferred from the first human to the second. Appropriate of the already previously created artificial and natural synapses and other hardware connectivity “ports” created for IBC would then be quickly reused to reestablish IBC towards that final step, to transfer self identity. Also, importantly, because largely no new artificial/natural synapse or other “port” hardware would need to be created for Step 3 of the invention, and since that final act (per Step 3) of self identity “transfer” would essentially constitute enabling access to already-transferred-and-stored-memory at the second brain, temporary simultaneous presence in both brains of the intended-to-be transferred self identity (i.e. the logical unification of the two logical centers of consciousness in the two brains into a single one), and then “switching off” the first brain's component of self identity, the process of self identity transfer would be reversible as long as the first body is physically alive.

[0194] Furthermore, multiple candidates for self identity transfer could be readied in advance (by completing extensive memory transfer to each) to reasonably ensure the availability of at least, one candidate when self identity transfer is finally elected.

[0195] These reversibility and multi-candidature aspects of self identity transfer would be of enormously significant practical benefit, as they would allow anticipatory full transfer (or simultaneous presence in two brains in preparation for full transfer) of self identity (i.e. in reasonable anticipation of possible physical death of the first body, for example if the first human is at the end stages of any terminal illness and therefore the body is likely to die in the imminent/near future, or if that first human is on an airplane that develops critical engine failure en route and appears unlikely to be able to land safely, so self identity is quickly simultaneously established in the second brain (i.e. simultaneous to that self identity also remaining in that human's own brain) over wireless IBC (to prevent disease transmission in the first example (of the terminally ill person), and wireless IBC would anyway be logistically mandatory in the second example (of the airline passenger)) for any one of multiple candidates who is healthy and who is then safely on the ground or elsewhere not on that particular airplane, and that self identity is either deliberately not fully transferred—if ever—until at the last, moment to maximally wait to complete Step 3 to be sure on the likelihood of any impending physical body-death or transferred anyway without waiting further, completing Step 3), and then if so elected reverse the process later while still in the simultaneous-self-identity-in-two-brains stage (i.e. with Step 3 in progress but not completed) or even at a post transfer stage (i.e. with Step 3 completed) should the anticipated physical death of the body doesn't actually happen (e.g. if the person in the above first example somehow recovers from that terminal illness, or if the airplane in the above second example is able to land safely). As indicated above, even if self identity is fully transferred, as long as the first body is still alive self identity can be transferred back in a mechanism similar to but significantly less cumbersome than how the identity was transferred out in the first place.

The Minimalism Option of Self Identity Transfer

[0196] An optional, overall much faster but less comprehensive, form of perpetual persistence of life with this invention using IBC would be to in large part forego the extensive non-essential memory transfer component, and undertake primarily just the self identity transfer component (inclusive of the fundamental, core essential memory absolutely mandatory for self identity transfer) over IBC. Post self identity transfer the individual would still be consciously able to recognize herself/himself in the second brain and also retain the minimal core sub-/unconscious memory (e.g. behavioral) traits and “adjust” into a modified, yet always acceptable (see the final two items of “Feasibility of invention” earlier in this section), rendition of herself/himself with selections of the already preexisting memory data in the second brain, albeit that second brain would lack most of the non-essential memory data that was present in the first brain.

CONCLUSION

[0197] IBC is logically reasonably feasible substantially exceeding the thresholds necessary for medically perpetual persistence of essential human life. That feasibility can be practically demonstrated by implementing the enablement principles outlined in the original patent application and in this section, in an R & D process that would take its due resources and time.

DESCRIPTIVE LEGENDS ON FIGURES

[0198] FIG. 1

[0199] Towards creating the integrated, augmented, single, logical center of consciousness, each of the 7 brains within the dashed box has in this example been shown to be linked only to Mary-I's brain. However, in reality some links could also be chosen to be among themselves (i.e. contained within the dashed box) and not all need to be directly linked to Mary-I. Ultimately, upon delinking them all, ordinarily at most one brain could have Mary-II-B, and the rest Mary-II-A.

[0200] FIG. 2

[0201] In this example, the 7 brains in the dashed box are selectively directionally interlinked among themselves and with Mary-I's brain, towards the formation of the integrated, single, logical, augmented center of consciousness. Note that the directions indicate information transport (hence consciousness transport prospect) direction. Again, upon delinking, ordinarily at most ONE Mary-II-B brain may be formed, and at the rest at most Mary-II-A. Some can choose to retain solely their original identities.

PREPARATION 2 FOR ETERNAL YOUTH AND IMMORTALITY WITH OUT-OF-THE-BODY EXPERIENCE APPLICATION BY TAKING KETAMINE...

Inventor:KAJISA ISAO

[0001]

The present invention relates to a ketamine dose-body application protein memory material transplant immortality Production Method 2 of human iPS rejuvenation body system drugs.
[0002]

Traditionally, there were technology related to ketamine dose-body application immortality preparation of human iPS rejuvenation body system drugs had no memory material transplantation.
[0003]

"Nikkei Science" January 2008 issue, 21 pages from 20 pages, 76 pages from 68 pages "Mainichi Shimbun" November 21, 2007, page 1 and page 3.
"Separate Nikkei Science perceived phantom" October 15, 2010, "Opening the door of iPS cells regenerative medicine" 114 pp -117 October 13, 2009, 202 pages from the 197-page "Mu" in November 2011 Pat, 85 pages from 60 pages
[0004]

Conventionally, to be achieved through state-of-the-art technology, since there were technology related to ketamine dose-body application immortality preparation of human iPS rejuvenation body system drugs had no memory material transplant.
[0005]

Hemishinku technology or right brain right corner gyrus electrode stimulation and right brain auditory cortex near the electrode stimulation and a video camera system and drug awareness energy that was out of body with ketamine taken by fixing put in infrared sensor in human iPS rejuvenation body body man with similar action is assumed to be all.
In addition it wants to perfect in protein storage material transplant.
[0006]

Body and memory consciousness of iPS immortality becomes possible in reliably-body can be stored substance portable ketamine dose of medicine.
[0007]

Below, it described in the series logically sentence when the embodiment of the present invention. First, two video camera back in Hemishinku technology or right brain right corner gyrus electrode stimulation or right brain auditory cortex near the electrode stimulation or special headset, the right side of the camera to the left of the camera image to the right eye to the left eye, from the body and at the same time stroking the chest of body can be immediately, the two consciousness energy can-body to a different location in a separate experiment ready-body.

Also I can surely-body with ketamine dose of medicine.

In human iPS technology to create a whole body such as organs and nerve to resemble me of young days is allowed to rejuvenation to make the outside of the cyborg.

The human iPS body to consciousness energy to realize the infrared sensor in the rejuvenation in the human iPS flesh and induction to the fixed all can do the same thing as human beings this new universal cells in their skin cells immortality because it can sense the infrared .

The retrovirus culture and cancer gene I prevent from becoming cancer in ultraviolet B wave or vitamin D.

Note To move the storage to young flesh long-term memory in the hippocampus of the brain transplant or aged brain is injected into young flesh of the brain that were made since the memory material is a kind of protein in iPS to extract the proteins of this total storage to memory also I want to transplant.

Human iPS rejuvenation ketamine dose-body application protein memory material of the body system drugs transplant immortality process 2 with the feature as more.

PROTEIN BEVERAGE ORAL DRUG 2 FOR IMMORTALITY OF LIFE USING HUMAN IPS CELL INITIALIZATION 4 GENE

Inventor: KAJISA ISAO

PROBLEM TO BE SOLVED: To provide a drug which completely achieves immortality of life by recent scientific application. ;SOLUTION: A human iPS cell initialization 4 gene is introduced into a human cultured cell to produce a protein for promoting a change to an iPS cell. The protein is extracted to permeate through the cell of the whole body of an aged man and an adult and to initialize each aged cell as to return it to a young cell. Therefore, immortality of life are achieved by orally drinking, while preventing injury to a brain and a human body, a protein beverage oral drug 2 for immortality of life using the human iPS cell initialization 4 gene

[0001]
The present invention relates to a human iPS cell initialization 4 gene utilization protein beverage oral immortality drugs.

[0002]
Traditionally, there was no technology for human iPS cell initialization 4 gene utilization protein beverage oral immortality drugs.

[0003]
"Nikkei Science" January 2008 issue, 76 pages from 68 pages.
"Newton" February 2008, 75 pages from 70 pages.
"Asahi Shimbun" May 30, 2009, page 9, evening

[0004]
Conventionally, to be achieved through state-of-the-art technology because there was no technology for human iPS cell initialization 4 gene utilization protein beverage oral immortality drugs.

[0005]
Human iPS cell initialization 4 gene to make a protein to promote changes to the introduced iPS cells to cell cultures of human.
It was taken out and drink in a manner harmless to the brain or body is for oral to return until the initialization of the cell aged spreads to cells throughout the body of the elderly human adult young cells.

[0006]
It kept the body of immortality.

[0007]
Below, it described in the series logically sentence when the embodiment of the present invention.
First, let me make a protein that encourages a change in the human iPS cell initialization 4 gene to

introducing iPS cells in cell cultures of human.
From the cultured cells of the entire body of the elderly adult human extract was taken, including the protein cells in the oral order to return until the young cells the initialization of each cell that was aging spreads ride in blood as a protein the brain and the human body harm drink out as no. Human iPS cells initialization 4 gene utilization protein beverage oral immortality drugs 2 with the feature as more.

[0008]
It is carried out as described above.

US2011137782

SYSTEM AND METHOD OF RECORDING, SHARING, AND STORING DATA AND MATERIALS FOR SELECTIVE RETRIEVAL

A method, a process, and a location for a customer to store life-time memories, feelings, emotions, and consciousness, or any other mental activity in a permanent database, based on a financing plan, aided by a collection of personal physical artifacts and personal biological data and materials in permanent physical storage, to share personal and communal information and physical collection with others, to build virtual and permanent personal and collective identities, and to prepare for the possible and probable human immortality where evocation of personal and communal consciousness and information is required when technology avails itself to make our consciousness alive again, either in biological form, in electronic form, in electro-biological form, or in any other possible form, so that our individual consciousnesses will live on both as separate entities and possibly form a unity with one another, in a state of community or singularity, thus achieving immortality.

BACKGROUND OF THE INVENTION

Field of Invention

[0002] This invention relates to a system and method of recording, sharing, and storing data and materials for selective retrieval.

BACKGROUND OF THE INVENTION

[0003] While much debate goes on about the reality and future of human immortality, the latest thinking not only points to its possibility, but almost inevitable probability. To understand the probability of human immortality in one form or another, let's start with the discovery and assertion of Francis Crick, the co-discoverer of DNA, who says this about human consciousness (or the “soul”) in his seminal book The Astonishing Hypothesis: The Scientific Search for the Soul:

[0004] The astonishing Hypothesis is that “You,” your joys and your sorrows, your memories and your ambitions, your sense of personal identity and free will, are in fact no more than the behavior of a vast assembly of nerve cells and their associated molecules.

[0005] Nothing more hopeful has ever come out of human existence than expressed in the quote above. What Francis Crick has pointed out is that, as humans, we will no longer need to rely on the existing 3 biological form we have taken to prolong our existence. Why? If our consciousness can be understood to be “the behavior of a vast assembly of nerve cells and their associated molecules,” then who is to say that this assembly of nerve cells and their associated molecules cannot be recreated or duplicated and then maintained to sustain our consciousness forever, thus enabling us to live forever? Who is to say that this behavior of a vast assembly of nerve cells and molecules cannot be achieved and maintained in some electronic or electro-biological form?

[0006] Ray Kurzweil, of Kurzweil Industries, has authored numerous books on the future development of the human race and on how technology will soon enable us to live forever. To his credit, he is widely known to have predicted the fall of Communism in Eastern Europe in his hooks; and there are many other predictions by him that have come truth. Bill Gates declares Ray Kurzweil to be the best person I know at predicting the future of artificial intelligence."

[0007] Here is the prediction of Ray Kurzweil about how technology will usher in human immortality in his best-selling book The Singularity Is Near:

[0008] . . . within several decades information-based technologies will encompass all human knowledge and proficiency, ultimately including the pattern-recognition power, problem-solving skills, and emotional and moral intelligence of the human brain itself.

[0009] . . . We will gain power over our fates. Our immortality will be in our own hands. We will be able to live as long as we want . . . . We will fully understand human thinking and will vastly extend and expand its reach. By the end of this century, the non-biological portion of our intelligence will be trillions of trillions of times more powerful than unaided human intelligence.

[0010] [When we reach the state of Singularity,] it will represent: the culmination of the merger of our biological thinking and existence with our technology, resulting in a world that is still human but that transcends our biological mots. There will be no distinction, post-Singularity, between human and machine or between physical and virtual reality. If you wonder what will remain unequivocally human in such a world, it's simply this quality: ours is the species that inherently seeks to extend its physical and mental reach beyond current limitations.

[0011] Essentially, these two experts, along with numerous others, have pointed to one unavoidable course of human development: our biological existence will soon be augmented or replaced by a non-biological or electro-biological existence, in one way or another, which may well usher in the age of immortality.

SUMMARY OF THE INVENTION

[0012] Essentially, Immordata is a method, a process, and a venue for our customers to store their electronic and biological data, as well as personal physical artifacts and biological data, for the purpose of creating an immortal consciousness, to share personal and communal information with others, to build virtual and permanent personal and collective identities, and to prepare for the possible and probable human immortality where evocation of personal and communal consciousness and information is required.

BRIEF DESCRIPTION OF THE DRAWINGS

[0013] FIG. 1 is a schematic diagram illustrating an exemplary system for data gathering, storing, and sharing;

[0014] FIG. 2 is an exemplary website for the system interface between customers and data;

[0015] FIG. 3 is an exemplary website interface where customers can to in to access the customer's account;

[0016] FIG. 4 is an exemplary website interface where customers may choose a data category to enter or retrieve the customers' data;

[0017] FIG. 5 is an exemplary website interface where customers may designate the category in which the customers may enter data;

[0018] FIG. 6 is an exemplary website interface where customer may record, enter, and retrieve audio data;

[0019] FIG. 7 is an exemplary website interface where customers may record, upload, and retrieve visual data;

[0020] FIG. 8 is an exemplary website interface where customers may record, upload, and retrieve other electronic data;

[0021] FIG. 9 is an exemplary website interface where customers may store and retrieve personal physical artifacts;

[0022] FIG. 10 is an exemplary website interface where customers may store and retrieve personal biological data and materials;

[0023] FIG. 11 is an exemplary website interface where customers may create various communities of any kind and size; and

[0024] FIG. 12 is a flowchart: detailing the method and system in which customers create accounts and communities, store data, share data, and retrieve data.

DETAILED DESCRIPTION

[0025] Here is the detailed description of how the Immordata will work, referring to the drawings, wherein like reference numbers refer to like components, a selective storage and retrieval system is shown at 100 in FIG. 1. The selective storage and retrieval system includes a network 102 operatively connected to a database 103. One or more users 101, such as a User A 101A, a User B 101B, a User C 101C, and a User N 101N, are in communication via a network with a network engine 102. The network engine 102 may include a website, one or more servers operating the networking website, or any other device or application capable of providing networking services via the network 102. The users 101 can access the services provided by the network engine via the network 102. Optionally, one or more of the users 101 may be able to access the network engine 103 directly.

[0026] The users 101 can access the network engine 102 via a computing device, such as a laptop or desktop computer, a cellular telephone, a personal digital assistant (PDA), a set top box, and so forth. The users 101 can view data about social network members via the network engine 102, enter data about themselves and possibly others, join network groups, and so forth. The users 101 are typically members of a networking website associated with the network engine 102, for example, and thus include the network members.

The Immordata Process, Method, and Other Elements:

[0027] 1. Immordata customers enter the website by using the process detailed below:
1.1. When customers enter the Immordata website, Immordata's home page will greet them, as shown in FIG. 2.
1.2. Immordata customers will sign in by using the sign-in website set up for the customers, where customers will need to use a User Name or an Email Address and also a User Password in order to enter the website, as shown in FIG. 3.
2. The Immordata Website: Immordata will establish the website for data storage, data sharing, and the building of Immordata individuals, families, communities, cities, states, ethnicities, countries,

the United Nations, and possibly the entire immordata humanity:
2.2. Web portals will be established as portals for customers to enter 1201, store, update, and share their written, audio, video, and all other electronic and personal data via the web interface, as shown in FIG. 12 at 1205. The data will be segmented into three distinct categories as shown in FIG. 12 at 1204: 1) one for public sharing, so others may have access to various published data, 2) one for sharing only within circles of family, friends, or any other community, and 3) one for private documentation that will only be viewed by each individual who enters the data and can be brought up as permitted by the executors of Immordata in the future for eventual establishment of individual immortality, as authorized by the individual in legal agreements.
2.3. Data submitted for publication will be subjected to data administrators' censorship as in FIG. 12 at 1220 and 1222. Once the submitted data passes censorship, the data will be published either to the general Internet public 1214 or to communities 1221 lithe submitted data does not pass censorship, the data will be permanently deleted 1218 and 1229 and the customer will be notified 1210.
2.4. Customers will be reminded to store their data permanently 1211 and customers can then submit data for permanent storage as in FIG. 12 at 1213 and 1215, but customers must sign up for financing plan, as shown at 1216, 1217 and 1223. If the financing plan is set up, then data is stored permanently 1213 and 1215
2.5. The websites will also enable our customers to build their communities 1226 as specified below, be they families, communities, races, ethnicities, countries, or all of humanity. As shown in FIG. 12, customers will be able to share their personal information to build communities of their own as they see fit at 1202. The data for these communities can be permanently stored or not, depending on the agreements between Immordata and these communities.
2.6. The websites will also direct our customers to store their Personal Physical Artifacts in storage centers across the globe in secure, locked-down, fire-proof, and quake-resistant facilities and the websites will also direct customers to store biological materials in biological storage in Immordata biological storage centers across the globe in secure lockdown, fire-proof, and quake-resistant facilities as shown in FIG. 12 at 1203 and 1225. Customers will be required to set up a financing plan 1224. If the customer does not have a financing plan set up, the customer will be rejected and notified 1227; if the customer has a financing plan, then the customer will be able to store physical artifacts and biological materials 1230 and the customer will be notified of the storage 1228.
3. Immordata process and method: This is the process and method for customers to store their daily activities, memories, feelings, emotions, and reflections, etc. Furthermore, Immordata customers will be able to save their personal physical artifacts and biological data as instructed by Immordata. The process and methods are listed below and shown in FIG. 4:

[0028] Data Category 1: Diaries Eternal

[0029] Data Category 2: Audios Eternal

[0030] Data Category 3: Visuals Eternal

[0031] Data Category 4: Other Personal Electronic Data

[0032] Data Category 5: Personal Artifacts Eternal

[0033] Data Category 6: Biological Data Eternal

3.1. Immortal Individuals:

[0034] 3.1.1. Immortal Written Entries: this is probably the best, the most direct, and the most intimate way to record one's consciousness for eternity. Customers' written entries of their memories and feelings, completed daily or otherwise, shall be stored permanently, to be used by our customers to build their own eternal consciousness and to build immortal communities of various kinds and sizes. As shown below, the contents of the immortal written entries will be categorized into three: 1)

Public, 2) Access Only for Families and Friends and Communities, and 3) Private. This function and the categorization will define all other data below to be stored with Immordata as shown in FIG. 5. The descriptions of the three categories will be further defined later in this patent application.

3.1.2. Immortal Audios: This shall be the voice recordings of our customers or other sounds and voices; the data is less direct, but it has dimensions unavailable in written words; it also records our biological vocal dimension and enriches the contents of the recorded consciousness. The contents of this kind of data will also have three categories: Public, or Access Only for Families and Friends and Communities, or Private. The audio recordings shall be stored permanently, to be used by our customers to build their own eternal consciousness and to build immortal communities of various kinds and sizes. Immordata customer will enter, modify, or retrieve their data by using the Immordata website as shown in FIG. 6.

3.1.3. Immortal Visuals: These are pictures or videos of customers; this data adds an even richer form of recording our consciousness, especially when we are recorded to discuss our memories, feelings, emotions, and reflections, or when they record other activities and observations. It also adds physical dimensions unavailable in audio and written recordings. The contents of this kind of data will also have three categories: Public, or Access Only for Families and Friends and Communities, or Private. These data elements are valuable in case our immortality may require sonic physical dimensions to establish our immortality. The visual recordings shall be stored permanently to be used by our customers to build their own eternal consciousness and to build immortal communities of various kinds and sizes. Immordata customer will enter, modify, or retrieve their data by using the Immordata website as shown in FIG. 7.

3.1.4. Other Electronic immortal Data: Customer may record any other electronic data they deem necessary to record their consciousness, such as medical records, publications of relevant subjects or events, or whatever electronic data. This data will enrich recordings of customers' consciousness. The contents of this kind of data will also have three categories: Public, or Access Only for Families and Friends and Communities, or Private. These recordings shall be stored permanently to be used by customers to build their own eternal consciousness and to build immortal communities of various kinds and sizes. Immordata customer will enter, modify, or retrieve their data by using the Immordata website as shown in FIG. 8.

3.1.5. Immortal Personal Artifacts: This will be a collection of personal physical artifacts, in limited spaces, to aid in the revival of personal consciousness of our customers. These personal physical artifacts, be they scrapbooks, old photos, letters, small collections, samples of any materials things with personal connections, will be stored permanently for customers, to be used by our customers to build their own eternal consciousness and to build immortal communities of various kinds and sizes. Immordata customer will enter, modify, or retrieve their data by using the Immordata website as shown in FIG. 9.
3.1.6. Biological Data Eternal: This will be a collection of personal biological data, to aid in the revival of personal consciousness of our customers. This personal biological data, whatever form it may take (DNA, tissue, MRI, etc.), will be stored permanently for customers, to be used by our customers to build their own eternal consciousness and to build immortal communities of various kinds and sizes. Immordata customer will be able to update their biological information continuously. The process for biological data storage is shown in FIG. 10.

3.2. Immortal Families: The data for the Immordata Families can be permanently stored or temporarily stored, based on the agreements between Immordata and the families:

3.2.1. Family Trees: Families can use the Immordata website and process to build their family trees, to share their activities, news, thoughts, photos, videos, physical artifacts, or any other such information as specified in the content categories later in this application. Access to the data can be categorized to allow different access permissions, such as public or family only.

3.2.2. Family Rooms: Families can use the Immordata website and process to share information on their family trees, to conduct live gathering on the web and record their activities, thoughts, feelings, voices, and all other information as specified in the content: categories later in this application. Families may also use the Family Rooms to record their birthdays, anniversaries, special events, etc., and Immordata will provide the service to send reminders to specified customers for those dates and events. Families may also use the Family Rooms to plan travels, events, and gatherings; and then they may use the Family Rooms to upload event photos, videos, audio recordings, and descriptions, etc., to be share among family members. Access to the data can be categorized to allow different access permissions, such as public or family only.

3.9.3. Family Eternal Child-Raising: As children, up to a certain age, cannot record their activities, families can use the Immordata website and process to record the activities of their children, to be shared with the children when they are old enough to record their own activities, memories, feelings, thoughts, knowledge, etc.

3.2.4 Family Reunions: Families can use the Immordata website and process for electronic family reunions, via web casts, live videos, or conference calls, on the web and then record their activities, thoughts, feelings, voices, and all other information as specified in the content categories later in this application. Access to the data can be categorized to allow different access permissions, such as public or family only.

3.2.5. Family Medical and Genetic Records: Families or individuals can use the Immordata website and process to record medical and genetic information, which will be accessible only to the individuals themselves or to others who are given the access by the collective family or their doctors who are granted the access by the collective family decisions.

3.2.6. Family Living Will: Families can use the Immordata website and process to record their will. This data will be accessible only to the family members who are given the access by the collective family or their lawyers who are granted the access by the collective family decisions or the government as mandated by the applicable law under the appropriate and applicable jurisdiction.

3.2.7. Families Immortal: Families can use the Immordata website and process to record and store immordata for the entire family and record their activities, thoughts, feelings, voices, and all other information as specified in the content categories later in this application. Access to the data can be categorized to allow different access permissions, such as public or family only.

3.3. Immortal Communities:

[0035] 3.3.1. Immortal Hoods: Individuals can use the Immordata website and process to build their immortal communities, be they neighborhoods, groups and communities of whatever specialty, such as artists, engineers, writers, inventors, etc., to share their products, activities, news, thoughts, photos, videos, physical artifacts, or any other such information as specified in the content categories later in this application and record their activities, thoughts, feelings, voices, and all other information as specified in the content categories later in this application. They may also use the immordata website to plan events and make announcements. Access to the data can be categorized to allow different access permissions, such as public or community only.

3.3.2. Immortal Cities: Individuals or cities can use the Immordata website and process to build their immortal cities, to share their products, activities, news, thoughts, photos, videos, physical artifacts, or any other such information as specified in the content categories later in this application and record their activities, thoughts, feelings, voices, and all other information as specified in the content categories later in this application. They may also use the Immordata website to plan events and make announcements. Access to the data can be categorized to allow different access

permissions, such as public or community only.
3.3.3. Immortal States: Individuals or states can use the Immordata website and process to build their immortal states or provinces or prefectures or whatever administrative regions, to share their products, activities, news, thoughts, photos, videos, physical artifacts, or any other such information as specified in the content categories later in this application and record their activities, thoughts, feelings, voices, and all other information as specified in the content categories later in this application. They may also use the Immordata website to plan events, conduct business, and make announcements. Access to the data can be categorized to allow different access permissions, such as public or specific community only.

3. Immortal Universities:

[0036] 3.4.1. As one of the purposes of Immordata is to establish a world in which learning will be for eternity for all interactive immordata individuals, it is fit and proper that Immortal Universities are to be established to benefit Immordata individuals. The purpose here may not be a diploma, but, instead, the Immordata individuals will matriculate into better beings all around, transcending the biological limitations.

3.4.2. Existing colleges and universities will set up their Immordata Colleges, Institutes, Universities, or any learning institutions of all kinds at the Immordata website to offer their education, for a fee, and to become a part of the Immordata world.

3.4.3. They may also use the Immordata website to plan events and make announcements. Access to the data can be categorized to allow different access permissions, such as public or community only.

3.4.4. Immordata will have the option to create its own Immordata University or any other higher education institution and offer its higher education services to Immordata customers and individuals.

3.5. Immortal Races and Ethnicities:

[0037] 3.5.1. Immortal races: Individuals or collective races can use the Immordata website a id process to build their racial communities, to share their cultural data, activities, news, thoughts, photos, videos, physical artifacts, or any other such information as specified in the content categories later in this application and record their activities, thoughts, feelings, voices, and all other information as specified in the content categories later in this application. They may also use the immordata website to plan events, conduct their business, and make announcements. Access to the data can be categorized to allow different access permissions, such as, public or community only.

3.5.2, Immortal ethnicities individuals or collective ethnicities can use immordata website and process to build their ethnic communities, to share their cultural data, activities, news, thoughts, photos, videos, physical artifacts, or any other such information as specified in the content categories later in this application and record their activities, thoughts, feelings, voices, and all other information as specified in the content categories later in this application. They may also use the immordata website to plan events, conduct their business, and make announcements. Access to the data can be categorized to allow different access permissions, such as public or community only.

3.6. Immortal Countries:

[0038] 3.6.1. Immortal countries: Sovereign countries or states can use the Immordata website and process to build their country or state communities, to share their data, activities, news, thoughts, photos, videos, physical artifacts, or any other such information as specified in the content categories later in this application and record their activities, thoughts, feelings, voices, visuals, and all other information as specified in the content categories later in this application. They may also use the Immordata website to plan events, conduct their business, and make announcements. Access to the data can be categorized to allow different access permissions, such as public or community only.

3.6.2. Immortal United Nations: The United Nations can use the Immordata website and process to share their data, activities, news, thoughts, photos, videos, physical artifacts, or any other such information as specified in the content categories later in this application and record their activities, thoughts, feelings, voices, and all other information as specified in the content categories later in this application. They may also use the Immordata website to plan events and make announcements. Access to the data can be categorized to allow different access permissions, such as public or community only.

3.7. Immortal Humanity:

[0039] 3.7.1. This is far-sighted, but if the Singularity occurs, as predicted by Ray Kurzweil, the entire Singularity may use the Immordata website and process to share their data, activities, news, thoughts, knowledge, photos, videos, physical artifacts, or any other such information as specified in the content categories later in this application and record their activities, thoughts, feelings, visuals, voices, and all other information as specified in the content categories later in this application.

3.7.2. Were that to happen, the Singularity may use the Immordata website and its process for whatever purposes, but within the confines of the law at the time when the Singularity occurs.

[0040] In FIG. 11, there is a preliminary webpage that enables Immordata customers to form their Immortal Families, Communities, Neighborhoods, Groups, Cities, Countries, Ethnicities. States/Provinces/Prefectures, United Nations, or whatever community, or the Singularity, as shown in FIG. 11.

[0000] In FIG. 12, a high-level flow chart delineates the process that governs the operations of Immordata process.

4. The Data Base Storage: Data storages will be established to permanently and securely store our customers' data resulting from our customers' writings, recordings, and collections.

4.1. Electronic data will be stored at the secure sites. Security will be of the uttermost importance, so the data storage will be established in the most secure locations.

4.1.1. Legal agreements will be established with customers on how data is to be shared or protected, and on how the eventual data will be used to establish individual immortality by using the data of their consciousness. The latest technology is available to store electronic data for thousands of years, and future technology will avail itself to preserve the data permanently.

4.1.2. Data Integrity: Immordata will establish a process in which the data will be stored permanently; Immordata will make sure Immordata data will forever be securely stored and will be safe to retrieve by ensuring all technological updates for the data storage.

4.2. Physical collections of Immordata customers will be stored in secured, fire-proof, water-proof, quake-resistant, and damage-proof storage facilities, to aid in the eventual evocation or retrieval of the consciousness data, in order to establish individual immortality by using their data of their consciousness. Security will be of the uttermost importance, so the data storage will be established in the most secure location.

4.3. Biological data: In case the future requires biological data, permanent DNA data and other biological data will be stored to enable customers to store their biological data, in case the eventual building of individual immortality needs the biological data. At the suitable time, Immordata may choose to form its own biological data storage company, so our customers will trust that their biological data is secure with Immordata, like the other data they have storied with Immordata,

4.4. Financing Plan:

[0041] 4.4.1. A financing plan will be established as an option for Immordata customers to enable the permanent data storage, until such a time as it is viable to transfer the Immordata from storage to a non-biological or altered biological form to let it: live permanently. The financial cost for permanent storage of all this data will be born by the principal amount in the form of an endowment and the resulting interest, as established by the financing plan.

4.4.2. Some of the Immordata costs will be borne by the income from advertising revenues as part of the Immordata is made public for viewing, discussion, and exchange.

5. Evocation of Immordata to Build Immortal Individuals, Families, or Communities of Varying Scales

[0042] 5.1. immordata will select an executive committee of the best scientists, community leaders, and prominent citizens in the world and form the Immordata Congress, whose responsibility is to assess the maturity of the technology to build and sustain immortal individuals in the future. The structure and decision-making process shall be determined by Immordata.
5.2. The decision of the Immordata Congress will be the decision Immordata will follow to evoke the private and public data to build immortal individuals.
5.3. The process to execute this decision will be outline by the Immordata Board of Directors and its executive officers, to be detailed in its company charter.
5.4. Immordata shall abide by all laws in the community in which it operates for all its operations and activities, without exception.

Further Definition of Immordata Contents:

[0043] This section is to detail some of the contents of the immordata, but not exclusively, so the patent's utility and its ease of application can be easily understood.

[0000] 1. Life Story: Below is a potential but not exhaustive list of events, things, people, places, and any other information, that: the Immordata customers may record, update, and store:
1.1. Memories of events at different stages in life:
1.1.1. early childhood
1.1.2. mid childhood
1.1.3. late childhood
1.1.4. teenage years
1.1.5. beginning of adulthood
1.1.6, college years
1.1.7. early professional years
1.1.8. middle professional years
1.1.9. middle age
1.1.10. conclusion of work life
1.1.11. retirement
1.1.12. any other events, real or imaginary or in dreams
1.2. People you know:
1.2.1. family members
1.2.2. friends
1.2.3. colleagues

1.2.4. neighbors
1.2.5. acquaintances
1.2.5. others you have met and known
1.2.7. any other people, real or imaginary or in dreams
1.3. Accomplishments of your life:
1.3.1. tasks you have accomplished with pride
1.3.2, plans for accomplishing future tasks
1.3.3. awards, prizes, certificates, diplomas, etc.
1.3.4. any and all accomplishments
1.3.5. things you wish you could accomplish
1.4. Knowledge you have:
1.4.1. things you have learned in school
1.4.2. things you have learned for your jobs
1.4.3. things you have learned about life's daily activities
1.4.4. things you have learned about the world
1.4.5, trivia
1.4.6. any other knowledge
1.5. Places where you have lived:
1.5.1. birth place
1.5.2. cities or villages or whatever place you have lived in
1.5.3, places where you have worked
1.6. Places you have visited:
1.6.1. places you have visited
1.6.2. recollections of those places that you have visited
1.7. Places you have dreamt about:
1.7.1. dreamscape: places you have dreamt up in sleep
1.7.2, places you have conjured up in daydreaming
1.7.3. imaginary communities or places you have conjured up creatively
1.7.4. any other place that has come to your mind or conscience
1.8. Places you wish to visit:
1.8.1. places you have read about and wish to visit
1.8.2. places you have seen visually but wish to visit in person
1.8.3. any other place you wish to visit

2. Feelings, Emotions, Thoughts, or any other mental activity or state: Immordata customers can use the Immordata website and databases to build their consciousness; that is, everyone can continuously make entries under each feeling, emotion, and thought in the categories (though not exclusive) listed below. This will enrich the volume of the consciousness, making sure that your consciousness is entirely you, beautifully you, and glorious you, rich, plentiful, detailed, and fully dimensioned. Furthermore, all the rich experiences, emotions, wisdom, and knowledge, etc., will build a collective human consciousness that is more interactive than otherwise possible. The vision is that, as an aggregate whole, this collective human consciousness, as supported by the individual consciousness, will evolve into something far greater than anything that we have thus far witnessed in human civilization. And, if we have the far-reaching vision of billions of years from now, we will need this collective human consciousness and knowledge to jump out of this universe, as this universe is, based on scientific consensus, to collapse in one way or another. If that is to happen, the most probable way to escape this universe is the electronic collective consciousness that Immordata and its customers and users will be able to start building.

2.1. Below is a list of possible but not exhaustive feelings, memories, emotions, thoughts, etc., which an Immordata customer can record and store:
2.1.1. happiness
2.1.2. joy
2.1.3. sympathy
2.1.4. understanding of humor
2.1.5. feeling of humor

2.1.6. empathy
2.1.7. ponderings
2.1.8. outrage
2.1.9. emotional discoveries
2.1.10. hatred
2.1.11. arrogance
2.1.12. regrets
2.1.13. pride
2.1.14, shame
2.1.15. disappointment
2.1.16. bias
2.1.17. resentment
2.1.18. envy
2.1.19. jealousy
2.1.20. yearning
2.1.21. dreams
2.1.22. wishes
2.1.23. desires
2.1.24. urges
2.1.25, anxiety
2.1.26, concerns
2.1.27. worries
2.1.28. peeves
2.1.29, love
2.1.30. bitterness
2.1.31, pain
2.1.32. suffering
2.1.33. frustration
2.1.34. depression
2.1.35. trivial and useless thoughts
2.1.36. musings
2.1.37. arrogance
2.1.38, snobbery
2.1.39. boredom
2.1.40. sweetness
2.1.41. bliss
2.1.42. exaltation
2.1.43. tedium
2.1.44. orgasm
2.1.45. sexual sensations
2.1.46, comfort
2.1.47. tactile touch and sensations
2.1.48. feel of different materials
2.1.49. athletic movements and reflexes
2.1.50, moral judgment
2.1.51, social responsibilities
2.1.52. communal duties and obligations
2.1.53. what you deem as the norm of society
2.1.54. what: to you is not acceptable social behavior
2.1.55. what you wish to know
2.1.56, what you wish to improve
2.1.57. what you would change about the world
2.1.58. how to build consensus and the importance of it
2.1.59. political opinions

2.1.60. uneasiness
2.1.61. fainting feeling
2.1.62, queasiness
2.1.63. madness
2.1.64. drunken feeling
2.1.65, elation
2.1.66, sadness
2.1.67. bewilderment
2.1.68, panic
2.1.69. sensations of heat, cold, chill, dryness, humidness, etc.
2.1.70. curiosity
2.1.71. embarrassment
2.1.72. hole-in-the-ground moments
2.1.73. earliest memories
2.1.74. betrayal
2.1.75. stubbornness
2.1.76. vengeance
2.1.77. all tastes
2.1.78. cowardice
2.1.79. hole-in-one feeling
2.1.80. being discriminated
2.1.81, being celebrated
2.1.82. any other feeling, emotion, knowledge, wisdom, thought, or mental activity that is “You”—specific to each individual Immordata customer
2.2. At the same time, Immordata customers can keep an Immordata diary, making daily entries and going back to the entries to make updates. This will be convenient and will help Immordata customers to build a habit of daily entries, which will enable the Immordata customers to detail their daily activities, feeling, emotions, reflections, etc., on a daily basis, thus making the collection of Immordata detailed, complete, rich, and comprehensive.

3. Building a Future:

[0044] 3.1. Community Forming: Using existing data, Immordata customers can build their communities of various kinds and levels, such as families, neighborhoods, cities, counties, states, provinces, prefectures, cantons, countries, or even the virtual United Nations.
3.2. Explorations of New Frontiers: Using existing data, Immordata customers can explore new potentials that are not yet thought of by the greatest theorists. But the data stored and operated by Immordata will build a base for them to spring from and provide a venue for such explorations.

The Different Levels of Data Storage:

[0045] Immordata data will be categorized into three different databases, as shown in FIG. 12: public data, limited-access data, and private data (1204), to be detailed below. The purpose of three different levels of data is that some Immordata data can be shared with the public; some may be shared only with families, friends, or authorized legal entities; but some will be private to the individuals only, and, as such, should be use only to be evoked at such a time as deemed appropriate by Immordata and the Immordata Congress to build individual immortality when such technology avails itself.

[0000] 1. The Public Immordata Data: Immordata customers will store data here that, is made public to varying groups:
1.1. Data public to everyone: This is the kind of data the Immordata customers will choose to be made public to anyone browsing the Immordata public information areas.
1.2. Data to be shared only with varying circles: This is the kind of data the Immordata customers

will choose to be made available only to people he/she will give consent to, such as friends, families, special groups, clubs, organizations, or whomever.
2. The Confidential Immordata Data for Families, Friends, Groups, and Communities of Their Choice: Immordata customers will store data here that will be shared with families and friends or authorized legal entities, such as doctors and lawyers, who have access to it. The data will not be available to the general public, but will be shared among Immordata customers who are granted the access by the Immordata customer, so that data can be shared within limited circles. The access can be granted or revoked by the Immordata customer who has created the data, but Immordata and the Immordata Congress will have the ultimate decision on whether the access should be granted, based on the power it is granted by the concurrent law.
3. The Private Immordata Data: Immordata customers will store data here that is guarded and will not be shared with anyone, as in the case of lawyer-client or physician-patient privileges, to be only used to build immortality for Immordata customers. Even when such information is used to build immortality for Immordata customers, this information will be used only for the immortal individual, not shared with anyone else in any situation for any purpose. It shall never be made public forever. This database is the crux of the trust between Immordata and its customers, without which Immordata cannot function or survive as a viable venue, method, or process to store our customers' data for purposes of immortality.

How It Benefits Mankind

[0046] The benefits of the present invention are many:

1. Learning Forever

[0047] 1.1. In the electronic form this Immordata existence will enable every consciousness or soul to learn forever, when the technology makes it possible for the immortal consciousness or soul to be live again.
1.2. The assumption is that all human short comings of the mind are rooted in the fact that the biological and neurological mind was constrained and confined within the biological boundaries of the human brain. A fully developed mind, in a form other than biological, will transcend its biological roots and rise above them to great heights of enlightenment, understanding, capabilities, and unlimited achievements.

2. Full Utilization of Latent Human Intelligence:

[0048] 2.1. We know much knowledge, wisdom, and creativity pass with the passing of a great mind or any mind. The recording or storage of these great minds could prevent such passing or loss. Just imagine, how many more ideas were still floating in Einstein's mind when he passed? And how many patent examiners like Einstein have passed without: writing down his or her great ideas? What would have happened if Leonardo de Vinci had written down his helicopter idea in more detail before his passing? Could the modern helicopter have been invented centuries earlier? Just imagine all the great ideas and minds of the billions of humans that have not been made known. How do we know those hidden or private ideas will not transform humanity entirely? What if suddenly we can harvest all those ideas and communicate all those ideas to each other for further advances? Could the human civilization see quantum leaps forward as a result?
2.2. I think it is a sure bet that, with the establishment of Immordata and later the evocation of Immordata to form immortal individuals and communal human immortality, this sea of knowledge, the vast collection of ideas, the immense wisdom, the endless scientific and technological know-how, and all that the human minds possess will make the human race not only a better race, but also a far more powerful race, enabling it: to achieve things one cannot even possibly imagine at this point in time.

3. Next Stage of Human Development

[0049] 3.1. Humans will probably no longer form prejudices related to physical attributes because the ultimate existence is in the realm of bio-electronics or some other advanced form.
3.2. It is possible that all souls will be connected in some form, thus forming a collective consciousness, which, as a part of the collective whole, is far more powerful, potent, productive, and beneficial than otherwise.
3.3. The probable immortal world in a form other than biological, such as the Singularity, also has a higher level or survivability, if we are to survive the disintegration of the universe in, say, 30 billion years, or in any length of time in which our universe will last.
3.4. This immortal world will enable souls or consciousness to continue to learn.
3.5. Because of this continuous learning, the souls and consciousnesses will evolve into higher beings with higher moral standards and better understanding, thus improving the souls and consciousnesses. Because of all that development, evil spirits and debased souls will transform to become better souls and consciousnesses.
3.6. Souls and consciousness will then command vast reservoirs of knowledge, thus being able to make better decisions, make new discoveries, improve the world tremendously, and eventually even find ways to survive the collapse of this universe and transport into another universe, were that to happen, to continue the human race and the human consciousness.

US2009062677

Method of Recording and Saving of Human Soul for Human Immortality and Installation for it

Inventor:BOLONKIN ALEXANDER ALEXANDROVICH

The inventor shows that a human soul is only the information in human brain. He offers a method for re-writing the human brain on electronic chips. This method allows for the modeling of a human soul in order to achieve man immortality. This method does not damage the brain but works to extend and enhance it. This method of writing and saving of Human Soul includes: writing of views which person see in during his life by a micro video recorder to a portable memory; writing of sounds which person speaks and hears by microphone; writing of person physical conditions by micro sensors; writing of time and dates; writing of person body position and so on. An Installation utilized the Method is comprising devices: micro video camera located at man head, microphone, computer (chip) for data processing, portable memory located at an person body and connected to the portable memory; portable recorder for writing of life film located at the man body and connected to the computer and to the portable memory; micro sensors for writing of person physical and environment conditions; a clock for writing of time, the micro sensors for writing of men body positions; navigation system, long time memory high capability storage and so on.

BACKGROUND OF THE INVENTION

1. Field of the Invention

[0005] The inventor shows that human soul is only the information in human brain. He offers a new method for re-writing the human brain on electronic chips. This method allows for the modeling of a human soul in order to achieve immortality. This method does not damage the brain but works to extend and enhance it.

[0006] 2. Description of the Related Art

[0007] Immortality is the most cherished dream and the biggest wish of any person. People seldom think about it while they are still young, healthy, and full of energy. But when they get some incurable disease or become old, then there is no bigger wish for them than to live longer, put off the inevitable end. And no matter what heavenly existence in the after-life is promised to them by religion, the vast majority of people want to stay and enjoy life here, on Earth, as long as possible. The inventor shows a real immortality can be only electronically.

Medical Science and the Issue of Immortality

[0008] A great many of doctors and scientists are currently working on the problems of health and longevity. Substantial means are spent on it, about 15-25% of all human labor and resources. There are certain achievements in this direction: we have created wonderful medications (e.g. antibiotics); conquered many diseases; learnt to transplant human organs; created an artificial heart, kidneys, lungs, limbs; learnt to apply physiological solutions directly into the blood stream, and to saturate blood with oxygen. We have gotten inside the most sacred organ—the human brain, even inside its cells. We can record their signals, we can agitate some parts of the brain by electric stimuli inducing a patient to experience certain sensations, images, and hallucinations.

[0009] We can attribute the fact that the average life span has increased two times in the last two hundred years to the achievements of modern medicine.

[0010] But can medical science solve the problem of immortality? Evidently, it cannot. It cannot do that in principle. This is a dead-end direction in science. Maximum it can achieve is increasing the average life expectancy another 5-10 years. An average person will be expected to live 80 years instead of 70. But what kind of person will it be? A very old one, capable of only existing and consuming, whose medical and personal care will demand huge funds.

[0011] The proportion of the elderly and retirees has increased steeply in the last 20-30 years and continues to grow depleting the pension funds and pressuring the younger generation to support them. So it is hard to say whether the modern success of medicine is a blessing or a curse from the point of view of the entire humankind, even though it is definitely a blessing from the point of view of a separate individual.

[0012] Humanity as a whole, as a civilization, needs active, able to work and creative members, generating material wealth and moving forward technology and science, not the elderly retirees with their numerous ailments and a huge army of those tending to them. It dreams not of the immortality of an old person, but of the immortality of youthfulness, activity, creativity, enjoying life.

[0013] Now there are signs of a breakthrough, but not in the direction the humankind has been working on all along, since the times of the first sorcerers to modern-day highly-educated doctors. Striving to prolong his biological existence, man has been chiseling, so to speak, at the endless stone wall. All he has been able to accomplish is only a dent in that wall—increased life expectancy, conquering some diseases, relieving suffering. As a payoff, the humanity has received a huge army of pensioners and retirees and gigantic expenditure on their upkeep.

[0014] Of course, one can continue chiseling at the dent in the wall further on, make it somewhat bigger, aggravating side effects. But we are already approaching the biological limit, when the cause of death and feeblemindedness is not a certain disease which can be conquered, but general deterioration of the entire organism, its decay on the cellular level, when the cells stop to divide. A live cell is a very complex biological formation. In its nucleus it has DNA—biological molecules consisting of tens of thousands of atoms connected between themselves with very fragile molecular links. Suffice it to say, that temperature fluctuation of only a few degrees can ruin these links. That is why a human organism maintains a certain temperature—36.7 C. Raising this temperature only 2-3 degrees causes pain, and 5-7 degrees leads to death. Maintaining the existence of human cells also presents a big problem for humanity involving food, shelter, clothes and ecologically clean environment.

[0015] Nevertheless, human cells cannot exist eternally even under ideal conditions. This follows from the atomic-molecular theory. Atoms of biological molecules permanently oscillate and interact with each other. According to the theory of probability, sooner or later the impulses of adjacent atoms influencing the given atom, add up, and the atom acquires enough speed to break loose from its atomic chain, or at least to transfer into the adjacent position (physicists say that the impulse received by the atom has surpassed the energy threshold which retains the atom in its particular place in the molecular chain). It also means that the cell containing this atom has been damaged and cannot any longer function normally. Thus, for example, we get cancer cells which cannot fulfill their designated functions any more and begin to proliferate abnormally fast and ruin human organs.

[0016] This process accelerates manifold when a person has been exposed to a strong electromagnetic radiation, for instance, Roentgen or X-rays, a high-frequency electric current or radioactive materials.

[0017] Actually, the process of deforming of the hereditary DNA molecule under the influence of weak cosmic rays can take place from time to time, leading sometimes to birth defects, or it may turn out to be useful for the survival properties. And this plays a positive role for a particular species of plants or animals contributing to their adaptability to the changed environment and their survival as a species. But for a particular individual such aberration is a tragedy as a rule, since the overwhelming majority of such cases are birth defects, with only few cases of useful mutations. And human society in general is suspicious of people who are radically different in their looks or abilities.

BRIEF SUMMARY OF THE INVENTION

[0018] The inventor shows that a human soul is only the information in human brain. He offers a method for re-writing the human brain on electronic chips. This method allows for the modeling of a human soul in order to achieve immortality. This method does not damage the brain but works to extend and enhance it.

[0019] This method of writing and saving of Human Soul includes: writing of views which person see in during his life by micro video recorder to portable memory; writing of sounds which person speaks and hears by microphone; writing of person physical conditions by micro sensors; writing of time and dates; writing of person body position, etc.

[0020] An Installation used the Method comprising devices: portable memory located at an person body; computer (chip) for data processing located at the person body and connected to the portable memory; micro camcorder (micro video camera) for writing of life film located at the person body and connected to the computer and to the portable memory; microphone for writing all sounds, which person speaks and hears, located at the person body and connected to said computer and to said portable memory; micro sensors for writing of person physical conditions located at the person body and connected to the computer and to the portable memory; micro clock for writing of time located at the person body and connected to the computer and to the portable memory; micro sensors for writing of person body positions located at the person body and connected to the computer and to the portable memory; long time memory high capability storage.

[0021] Writing of human soul is absolutely new idea of modeling, re-writing, and saving of human soul and using it for person immortality. No any materials about this method and installation.

BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWINGS

[0022] FIG. 1. Principal scheme of the installation (equipment) of writing human soul (full information about human life) for man immortality. The cells contain:

1) micro devices (micro video camera, microphone, computer (chip), portable recorder, portable power source, portable memory, etc.);
2) micro sensors and devices for writing of brain impulses, oscillation, fluctuation and a state of man health and person physical conditions (for example: sensors of blood press, heart palpitation, skin resistance, perspiration, skin temperature, respiration activity, mouth water, chill, rigor-like tremor, catarrh, muscle stress, blood mixture, pain, brain oscillation and so on);
3) micro sensors for writing of body positions (for example: sensors of motion, acceleration, distance, angle, mutual position, and so on);
4) devices for measure of outer environment conditions about man such as air temperature, pressure, humidity, gas composition, smells, wind, illumination, radiation, and so on;
5) devices of a portable navigation system for measure of a person position at Earth surface (for example, GPS navigation system);
6) emergency 911 communication;
7) portable power source (for example: chemical, solar, nuclear batteries, and so on);

[0030] FIG. 2. Re-writing the information from the portable memory to the high capability long-term storage,

[0031] FIG. 3. Location of video camera at human head (forehead).

DETAILED DESCRIPTION OF THE INNOVATION

1. Brief Description of Previous Works by the Inventor

[0032] In a series of articles (see referenced list at the end) the inventor shows that the purpose of Nature is to create Super Intelligence (SI). With its ability to understand the Universe, advanced entities with SI Power will be able to survive major cataclysms. There is the Law of Increasing Complexity (in opposition to the Entropy Law—increasing chaos). This Law created biological intelligence (people). Human have since became a sovereign entity on the Earth and in Nature above all other creatures.

2. Electronic Immortality. Advantages of Electronic Existence

[0033] In the noted works the author has shown that the problem of immortality can be solved only by changing the biological human into an artificial form. Such an immortal person made of chips and super-solid material (the E-man, as was called in his articles) will have incredible advantages in comparison to conventional people. An E-man will need no food, no dwelling, no air, no sleep, no rest, and no ecologically pure environment. His brain will work from radio-isotopic batteries (which will work for decades) and muscles that will work on small nuclear engines. Such a being will be able to travel into space and walk on the sea floor with no aqualungs. He will change his face and figure. He will have super-human strength and communicate easily over long distances to gain vast amounts of knowledge in seconds (by re-writing his brain). His mental abilities and capacities will increase millions of times. It will be possible for such a person to travel huge distances at the speed of light. The information of one person like this could be transported to other planets with a laser beam and then placed in a new body.

[0034] Such people will not be awkward robots as in the movies. An artificial person will have the opportunity to choose his or her face, body and skin. It will also be possible for them to reproduce and then avoid any period of adolescence including the need for education. It will be impossible to destroy this entity with any kind of weapons, since it will be possible to copy the information of their minds and than keep such information backed up in separate distant locations. As was written in the science fiction book, “The Price of Immortality”, by Igor Getmansky (Moscow, Publish House ECSMO, 2003, Russian) an artificial person will have all of these super-human abilities.

3. What are Men and Intelligent Beings

[0035] All intelligent creatures have two main components: 1. Information about their environment, about their experience of interacting with nature, people, society (soul) and 2. Capsule (shell), where this information is located (biological brain, body). The capsule supports existence and stores information and programs for all of its operations. The capsule also allows the creature to acquire different sensory information (eyes, ear, nose, tongue and touch) and it moves to different locations in order to interact with the environment.

[0036] The main component of an intelligent being is information (soul). The experiences and knowledge accumulated in the soul allows the entity to interact more efficiently in nature in order to survive. If the being has more information and better operational programs (ability to find good solutions), then it is more likely thrive.

[0037] For an intelligent being to save its soul it must solve the problem of individual immortality. Currently man creates a soul for himself by acquiring knowledge from parents, educational systems, employment and life experiences. When he dies, most knowledge is lost except for a very small part which is left through works, children and apprentices. Billions of people have lived on Earth, however, we know comparatively little about ancient history. Only after the invention of written language did people have the capacity to easily save knowledge and pass it on to the next generation.

[0038] As discussed earlier, the biological storage (human brain) of our soul (information) is unreliable. The brain is difficult to maintain and requires food, lodging, clothes, a good environment and education, etc. To support the brain and body, humans spend about 99% of their time and energy, and eventually what knowledge is gained is taken to the grave in death.

[0039] There is only one solution to this problem—re-write all of the brain information (our soul) in more strongly based storage. We must also give the soul the possibility to acquire and manipulate information from the world. This means we must give sensors to the soul so it may have communication and contact with people and other intelligent beings. We must give the soul a mobile system (for example, legs), systems for working (hands), etc. thus giving the soul a new body in which to LIVE.

[0040] The reader may ask—these ideas seem interesting, but how does one we re-write a human soul to live within a new carrier, for example, in electronic chips?

4. The Main Problem With Electronic Immortality—Re-Writing Brain Information (Soul) to Electronic Chips is That it's Impossible to do This With Current Technology

[0041] At present scientists are working to solve this problem. They know that the brain has about 15 billion neurons, and every neuron has about ten connections to neighboring neurons. Neurons gain signals from neighboring neurons, produce signals and then send these signals to others neurons. As a result, humans are able to think and find solutions. On the bases of this way of thinking, humans can come to solutions without exact data. (Concepts of brain were described in my previous articles. For example, see “Locate God in Computer-Internet Networks” or “Science, Soul, Heaven and Supreme Mind”. See also my articles on the Internet and references at end of this article.).

[0042] Scientists are learning how to take individual neurons on micro-electrodes and record their impulses. The ideas of scientists are very simple—study how single neurons and small neuronal network work and then model them by computer. They hypothesize that if we can model 15 billion neurons in a computer they will learn how the brain works, and then they will have Artificial

Intelligence equaling the human brain.

[0043] In my previous work I show this as a dead-end direction for Human Immortality. It's true that we'll create an Artificial Intelligence (AI) that will be more powerful than the human mind. However, it will be HIS AI, and a NEW entity altogether. Our purpose is focused on preserving the CONCRETE PERSON now (more exactly—his SOUL) in a new body in order to achieve immortality.

[0044] Why is it impossible to directly write the information of the human brain onto a chip? Because the human brain is constantly changing and neurons permanently change their states. Imagine you want to record the state of a working computer chip. The chip has millions of logical elements which change their state millions of times per second. It is obvious that if you write in series (one after other) the current state of the chip (it is impossible to instantly write ALL states of the chip's elements). To instantly write all neurons one would need to insert a microelectrode into EVERY neuron, this would destroy the human brain before the writing was complete.

[0045] I offered another method for the solution of the Main Problem of Immortality.

5. Modeling of Soul for a Concrete Person

[0046] As said, straight re-writing of a human mind (human soul) to chips is very complex. Straight re-writing is not possible in the near future. All scientific works studying the work of human brains at the present time are useless for the main problem of immortality. They are also unworkable for the problem of artificial intelligence (AI) in the near term, because the brain solves problems by way of general estimations. AI solves problems based on more exact computation and logical data.

[0047] To solve the Main Problem of Immortality (MPI) the author offers a method of "MODELLING SOUL" of a concrete person. This method does not require interventions into the brain of a given person. This method may be applied IMMEDIATELY at the present time. But an accurate modeling is needed depending on the modeling period.

[0048] Before describing this method, let us analyze the human soul and what components are important for each person and his environment. All information in the human brain (soul) may be separated in two unequal groups: 1. the Memory (permanent knowledge) about the person's life (all that has been seen, heard, made, felt, people which he has met, his (her) behaviors, opinions, wishes, dreams, programs of activity, etc.), environment, and 2. Methods of processing this information, i.e. producing new solutions and new behaviors based on this knowledge.

[0049] The first part (knowledge) is very large. It fills most of the memory and remains relatively constant (you remember your life, history and you can only fill it by what was in the past). The second part (methods for deciding, producing solutions based in your knowledge) is relatively small and constantly changing because of new information, facts and life experiences.

[0050] However, the most important part of a human soul can be written without any problem now. Industry is producing cheap micro-video recorders as small as a penny, microphones at grain size, and micro-sensors for vital signs (breathing, palpitation, blood pressure, skin resistance, perspiration, movement of body parts, etc.). These measurements allow for easy recording of not only the physical state, but of his moral state (joy, pleasure, grief, trouble, anxiety, nervousness, etc). For example, lie detectors are able to define not only the state of a man, but also the truth of his words. Now we can measure and record brain commands and we can produce small cards with four gigabytes of memory.

[0051] It would be easy to attach a video recorder and microphone to a man's forehead and then attach sensors to the body and record all that he sees, hears, speaks, his feelings, reactions, and activity. And then re-write this information into a personal hard drive (long-term memory of high capacity storage) at the end of each day. As a result, there is a record of the most important part our soul—history of life, feelings, environment, behaviors and actions. This would be more detailed than what is captured by the real man, because the humans forget many facts, feelings, emotions, and personal interactions. The electronic memory would not forget anything in the past. It would not forget any person or what they were doing.

[0052] But what about the second smaller part of the human soul—producing solutions based on personal knowledge—perhaps asks the meticulous reader.

[0053] This could be restored by using past information from the real man in similar situations. Moreover, an electronic man could analyze more factors and data in order to throw-out and exclude actions and emotions that happened under bad conditions. The electronic man (named E-being in my previous works) would have a gigantic knowledge base and could in a matter of second (write to his brain) produce the right answer, much faster than his biological prototype. That means he would not have the need for the second smaller part of memory.

[0054] Considering the environment and friends, the following is an important part of a man's soul: his relationship with parents, children, family, kin, friends, known people, partners and enemies. This part of his soul will be preserved more completely than even his prototype. Temporary factors will not influence his relationship with his enemy and friends as would happen with his former prototype.

[0055] There is one problem which may be troubling for some: if we were to record every part of a person's life, how do we keep intimate moments a secret? There are (will be) ways to protect private information which could be adapted from current usage, for example, the use of a password (known only by you). Also there may be some moments you choose not to record information or decide to delete the information from memory.

[0056] The offered system may become an excellent tool for defense again lies and false accusations. You may give the password in one given moment of your life, which proves your alibi or absence from the accusations.

[0057] Some people want to have better memory. Video takes 95% of storage capacity, sound takes 4% and the rest takes 1%. In usual situations, video can record only separate pictures, sound only when it appears. This type of recording practice decreases the necessary memory by tens of times. But every 1.5-2 years chip storage capacity doubles. There are systems which will compress the information and then may select to record the most important information (as is done in the human brain). During your life, the possibility to record all information will be available for all people. This type of recording apparatus will be widely available and inexpensive. It's possible now. The most advanced video recorder or DVD writes more information than a CD.

[0058] This solution (recording of human souls) is possible and must be solved quickly. By mass production (large productions) the apparatus will become inexpensive. The price will drop to about $300-1,000. If we work quickly we can begin recording and then more fully save our souls. The best solution is to begin recording in children when they become aware of “I”. But middle and older people should not delay. Unrecorded life periods may be restored by pictures, memories, notes, diaries and documents. Soul recovery will only be partial but it's better than nothing.

[0059] These records will also be useful in your daily life. You can restore recorded parts of your life, images of people, relatives, and then analyze and examine your actions for improvement.

6. Disadvantages of Biological Men and Biological Society

[0060] People understand Darwin's law, “survival of the fittest”. For a single person, this law is the struggle for his/her personal existence (life, well-being, satisfaction of requirements, pride, etc.). In a completely biological world built on Darwinian law the strongest survives and reaches his goal. Though they may be intelligent, humans are members of the animal world. They operate as any other animal in accordance with animal instincts of self-preservation. If one is poor, at first he struggles for food (currently half of world's population is starving), dwelling, and better living conditions. When one reaches material well-being, he may struggle for money, job promotion, reputation, renown, power, attractive women (men), and so on. Most people consider their activities (include official work) in only one way—what will I receive from it? Only a small number of people are concerned with the idea of sacrificing themselves to the well-being (seldom giving up their life) of society at large.

[0061] As a result, we see human history as a continuation of wars, dictatorships, and repression of people by power. Dictators kill all dissidents and opponents. Most people try to discriminate against opponents and play dirty against their enemy. There are murders, rapes, violence, robbery, underhand actions, fraud, and lying at all levels of society especially in lesser developed countries. Each person only cares for himself and his family and does not care how his actions effect other people or society.

[0062] Democratic countries try to cultivate a more civilized society. They create laws, courts, and have police. Dictator regimes, on the other hand, make only the law they want. I could give thousands of examples to verify this concept. But hundreds of millions of people are killed by war, aggressive campaigns, repressions, genocides, and thousands of criminals in the everyday world are a good illustration of this.

[0063] The human brain allows us to reach great success in science and technology. However, as a biological heritage, struggling for his INDIVIDUAL existence in a bloody, dangerous world, humans spend much of their resources on mutual extermination of intelligent beings. Moreover, humans have created ever powerful weapons (for example, nuclear and hydrogen bombs), which could wipe out humanity. In time, existence may depend on the volition of one man—perhaps the dictator of a nuclear state.

[0064] The second significant drawback to the biological body—is that it spends 99.99% of its effort and resources simply to support existence. Such as food, lodgings, clothing, sex, entertainment, relaxation, environment, ecological compatibility. Only a very small part is uses for scientific development and new ideas and technology. The reader may see something wrong here.

[0065] States use a parentage of their revenue for research into science and technology. This percent is used NOT for NEW ideas, but is used to commercialize modern processes All research is included in the state budget under the name, “Science and New Technology”. But much of this research has little relation to real new scientific progress. Even it the US, states spend only a small part of the assigned money on new science because state officers do not understand the research. People, organizations, and companies fight for a piece of the pie. Geniuses are rare and usually don't have the capacity to move forward because they must promote and pay for new ideas from their own empty packets.

[0066] Yet, science and technology has seen success. Most advancement (90%) was made recently in the 20th century, when governments started to finance a few scientific projects (compared with the millions of years of human existence). However, our current knowledge and new technologies are far from what we will eventually have. The first government of an industrialized country to understand and realize the leading role of new science and innovation will become powerful.

7. Electronic Society

[0067] The electronic society will be a society of clever electronic beings (or E-being, as they named in my articles). Most of the reasons and stimulus which incite men to crime, will be absent in E-beings. E-beings will not need food, shelter, sex, money, or ecology, which are the main factors in crime. E-people will not have intense infatuations or be distracted by behaviors, because they will have vast knowledge about the open electronic society. Their main work will be in science, innovations, and technologies. They will save their mental capacity for the production of chips and bodies, scientific devices, experimental equipments, space ships and space station, etc. They will need a number of robots, which do not need a big brain. It is likely they will award these robots better minds and memory. It is also likely that E-man will unite in a common distributed hyper-brain, which will become a sovereign of the Universe (God).

[0068] Nature is infinite and the development of a Super Brain (God) will not be limited. On the other hand, biological people will have limited mental capabilities. It will be difficult for them to image and predict the development and activity of Super beings, which we will generate.

[0069] Many, especially religious people, object because they say electronic beings will not have human senses such as love, sympathy, kindness, humanism, altruism, and the capacity to make mistakes, etc. E-beings are not people. Look back at human history. Human history shows that kindness played a very small role in human life. All human history is the history of human vices and human blood: struggle for power, authority, impact, money, riches, territory, and states. All human history is filled with fraud, underhanded actions, and trickery. Ordinary people were only playthings, flock of sheep for the tyrants and dictators.

[0070] Some people object that with an electronic face humans will loss the joy of sex, alcohol, narcotics, appreciation of art, beauty, nature, etc. My answer to this question is in my article “Science, Soul, Heaven, and Supreme Mind” (http://Bolonkin.narod.ru). The brief answer is that electronic humans will enjoy all this in a virtual world or virtual paradise. Time will run millions of times faster in the virtual World. E-man will spend a few seconds of real time and live millions of years in the paradise. He will enjoy any delight imaginable, include sex with any beautiful women (or handsome men), feel the emotions of any commander, leader, criminal, or even a dog.

8. Lot (Fortune) of Humanity

[0071] Biological humanity will be gradually transformed to electronic beings. Old people, when their biological bodies can not support their brains, will continue their existing in electronic bodies after death. They will become young, handsome, robust, and. Fertility in biological men will decrease. Birth-rates are less than death-rates in many civilized countries now (for example in France). Population growth is mainly supported by emigration from lesser developed countries. When education levels increase, birth-rates will fall.

[0072] For a time, biological and electronic people will exist together. However the distance between their capabilities will increase very quickly. Electronic people will reproduce (multiple) by coping, learn instantly, and will not need food or dwellings. They will work full days in any condition such as in space or on the ocean floor. They will gain new knowledge in a short time. They will pass this knowledge on to others who do not have enough time. The distance between biological and artificial intellects will reach a wide margin so that biological people will not understand anything about new science as monkeys do not understand multiplication now even after much explanation.

[0073] It is obvious, clever people will see that there will be a huge difference between the mental abilities of biological and electronic entities. They will try to transfer into electronic form and the ratio between biological and electronic entity will quickly change in electronic favor. A small number of outliers will continue to live in their biological body in special enclaves. They will not have industrial power or higher education and will begin to degrade.

[0074] Naysayers may promote laws against transferring into an electronic man (as cloning is forbidden now in some states). However, who would renounce immortality for themselves, especially while they are young and healthy? One may denounce immorality as blasphemy, but when your (parents, wife, husband, children) die, especially if you are near death yourself, one comes to understand that life is extremely important. The possibility to live forever, to gain knowledge that improves life, will also allow one to become a sovereign force in the Universe.

[0075] We summarize all said in the following steps and devices:

Method

[0000]
1. A method of writing and saving of Human Soul for man immortality comprising of steps:
(a) positioning a micro video camera at a man head;
(b) positioning a portable recorder at a man body;
(c) positioning a portable memory at said man body;
(d) positioning a microphone at said man body;
(e) positioning a portable computer at said man body;
(f) positioning a portable power source at said man body;
(g) connecting said micro video camera, said microphone to said micro computer, said portable recorder, said power source and said portable memory;
(h) programming said computer for writing needed data from said micro video camera, microphone whereby said portable recorder to said portable memory;
(i) writing of views which said man see in during his life whereby said micro video camera, said portable computer, said portable recorder to said portable memory;
(j) writing of sounds which person speaks and hears in during his life whereby said microphone, said portable computer, said portable recorder to said portable memory;
(k) writing of time and dates whereby said portable computer, said portable recorder to said portable memory;
(l) connecting said portable memory to a stationary long term high capability memory;
(m)periodical rewriting an information from said portable memory to said stationary long term high capability personal memory;
(n) read-protecting said information.
Note: The simplest method can contain the parts of these steps, for example, writing only video and sound.
2. The Method of writing of Human Soul for man immortality as recited above comprising at least one of the following additional steps:
(a) writing of brain impulses, oscillation, and a state of a man health and person physical conditions whereby micro sensors, said computer, said recorder to said portable memory;
(b) writing of a person body position whereby micro sensors, said computer, said recorder to said portable memory;
(c) writing of outer, environmental conditions around said man whereby micro sensors, said computer, said recorder to said portable memory;
(d) writing person position at Earth surface whereby portable navigation system, said computer, said recorder to said portable memory;
(e) permanently writing said conditions and information to said portable memory;
(f) permanently writing said condition and information to said portable memory except slipping time;
(g) periodically writing said condition and information to said portable memory;
(h) writing said condition and information only in selected time to said portable memory;
(i) data processing before writing to said portable memory;
(j) data compressing before writing to said portable memory;
(k) data coding of said information;

(l) transferring of said information to stationary receiver.
3. The Method of writing of Human Soul for man immortality as recited above comprising at least one of the following additional steps:
(a) writing of said man physical conditions includes at least one of the following: opening of man eyes, body temperature, blood press, heart palpitation, skin resistance, perspiration, skin temperature, respiration activity, mouth water, chill, rigor-like tremor, catarrh, muscle stress, blood mixture, pain;
(b) writing of said outer conditions includes at least one of the following: air temperature, pressure, humidity, gas composition, smells, wind, illumination, radiation;
(c) computer analyzing of said man physical and outer conditions;
(d) informing about emergency situation said man and an outer authority;
(e) long time saving whereby said high capability long-term memory.

Installation (System)

[0000]
4. An Installation utilized the Method of writing and saving of Human Soul for human immortality comprising devices:
(a) micro video camera located at man head for writing of views which said man see in during his life;
(b) microphone located at said man body for writing all sounds which person speaks and hears in during his life;
(c) portable computer for data processing located at said man body and connected to said micro video camera and said microphone;
(d) portable clock for writing of time located at man body and connected to said computer;
(e) portable recorder located at man body and connected to said computer, said micro video camera and said microphone;
(f) portable memory located at an said man body and connected to said recorder;
(g) portable source located at said man body and connected to said computer, said micro video camera, said microphone and said memory;
(h) stationary high capability long-term memory for rewriting of information from said portable memory;
(i) communications located at said man body and connected said micro video camera, said microphone, said computer, said recorder, said memory, said power source in a common net.
Note: The simplest instillations can contain the parts of these devices, for example, devices for writing video and sound.
5. The Installation recited above comprising at least one of the following devices:
(a) micro sensors for writing of brain impulses, oscillation, fluctuation and a state of a man health and man physical conditions located at said person body and connected to said computer and to said portable recorder;
(b) micro sensors for writing of man physical conditions located at said person body and connected to said computer and to said portable recorder;
(c) micro sensors for writing of a state of a man health and person body positions located at said person body and connected to said computer and to said portable recorder;
(d) devices for measure of outer environment conditions located at man body and connected to said computer;
(e) devices of a portable navigation system for measure of a person position at Earth surface located at said man body and connected to said computer and said recorder;
(f) devices for emergency communications located at man body and connected to said computer;
(g) portable power source located at said person body and connected to said micro sensors, said devices, said computer, and said portable memory.
6. The Installation recited above comprising at least one of the following devices and features:
(a) said micro video camera is located in man spectacles or on head decoration;
(b) said computer is programmed chip for writing of said data in selected time, data processing and

re-writing them to said high capability long-term data storage;
(c) memory card used as said portable memory;
(d) said physical condition sensors are at list one of the following: blood press, heart palpitation, skin resistance, perspiration, skin temperature, respiration activity, mouth water, chill, rigor-like tremor, catarrh, muscle stress, blood mixture, open eyes, pain;
(e) said body position sensors are motion, acceleration, distance, angle, mutual position;
(f) said devices for measuring of the outer environmental conditions includes at least one of the following values: air temperature, pressure, humidity, gas composition, smells, wind, illumination, radiation;
(g) said power source is at least one of the following: chemical, solar, nuclear batteries;
(h) said high capability long-term date storage is recorder used CD, DVD, type devices, memory carts.

Process of love

Inventor:KNAUER GEORGE

This invention combines God's gift of reincarnation with love resulting in immortality.This invention combines God's gift of reincarnation with love resulting in immortality

that they are complete, up-to-date or fit for specific purposes.

SUMMARY OF THE INVENTION

[0001] This invention resulted from my combining God's gift of reincarnation with love.

[0002] In Chapter 4 of the London translation of the Holy Bible, paragraph 8 says "He that loveth not knowth not God; for God is love." and paragraph 16 says "And we have known and believed the love that God hath to us. God is love; and he that dwelleth in love dwelleth in God, and God in him."

[0003] The scope and extent of my invention is defined in the following claim:

[0004] 1. The process of combining God's gift of reincarnation with love resulting in immortality.

US2004005535
Process of reincarnation

Inventor: KNAUER GEORGE

SUMMARY OF THE INVENTION

[0001] This invention resulted from my combining Einstein's Theory of Relativity and Newton's Second Law of Physics.

[0002] Reincarnation is defined in Webster's Third New Inernational Dictionary as "rebith". Thus my invention is a process of rebirth or in other words immortality.

JP2008178692
IMMORTALITY DEVICE 3, ADOPTING REJUVENATION METHOD WITH APPLICATION OF-OUT-OF-BODY EXPERIENCE...

Inventor: KAJISA ISAO

PROBLEM TO BE SOLVED: To provide an immortality device. ;SOLUTION: The immortality device includes processes as follows: (a) Conscious energy is placed to be out of body by a Hemi-Sync technology, right brain right angular gyrus electrode stimulation, or special video-camera; (b) Organs and nerves are generated from the pluripotent stem cells of adult human fibroblasts, and an outer body is generated from the pluripotent stem cells of the adult human fibroblasts is formed on a cyborg's bones made of a protein so that an external cyborg could be formed like oneself of its youth; (c) The conscious energy is lead to and fixed in the cyborg body generated from the pluripotent stem cells of the human adult by an infrared sensor.

[0001]

The present invention relates to a human adult skin universal cell-based protein made cyborg rejuvenation method-body application immortality device 3.
[0002]

Traditionally, there was no technology for human adult skin universal cell-based protein made cyborg rejuvenation method-body application immortality device 3.
[0003]

"Nikkei Science" January 2008 issue, 21 pages from 20 pages, 76 pages from 68 pages "Mainichi Shimbun" November 21, 2007, page 1 and page 3.
[0004]

Conventionally, to be achieved through state-of-the-art technology because there was no technology for human adult skin universal cell-based protein made cyborg rejuvenation method-body application immortality device 3.
[0005]

Body human similar behavior plus the artificial intelligence by the conscious energy that was out of body in Hemishinku technology or right brain right corner gyrus electrode stimulation and a video camera system to be fixed and put in the infrared sensor to a human adult skin universal cell-based protein made cyborg and it shall be all.
[0006]

Of immortality with human consciousness body also becomes possible to cyborg close endlessly in human beings.
[0007]

Below, it described in the series logically sentence when the embodiment of the present invention. First, two video camera back in Hemishinku technology or right brain right corner gyrus electrode stimulation or special headset, the left side of the camera image to the right eye to the left eye the right side of the camera, from the body and at the same time stroking the chest-body can immediately, another The two consciousness energy can-body to another location in the experiment ready-body.
The gist of the protein made cyborg made from human adult skin cells, such as universal organs and nerve from the human adult skin universal cells resemble me of young days is allowed to rejuvenation to make the outside of the cyborg.

This universal that human adult skin universal cell-based protein made cyborg body to consciousness energy can be the same thing all human beings are fixed by inducing in the human adult skin universal cell-based protein made cyborg body in the infrared sensor because it can sense the infrared We realize the rejuvenation immortality in their own skin cells in the cell.
The retrovirus culture and cancer gene I prevent from becoming cancer in ultraviolet B wave or vitamin D.
Human adult skin universal cell-based protein made cyborg is guided by the above as logical rejuvenation method-body application immortality device 3.
[0008]

It is carried out as described above.
[0009]

the industrial applicability of the demand of this device in human adult skin cells universal use and aging made even greater progress of body applied technology by the infrared sensor to the protein made cyborg advances is understood to be high.

JP2007135597
IMMORTALITY APPARATUS PRODUCED BY APPLYING PROTEINACEOUS CYBORG-TYPE OUT-OF-BODY EXPERIENCE 2

Inventor:KAJISA ISAO

PROBLEM TO BE SOLVED: To produce a complete proteinaceous cyborg for an immortality device produced by applying out-of-body experience. ;SOLUTION: Consciousness energy isolated from the body by a Hemi-sync technique or right brain right angular gyrus is introduced into a proteinaceous cyborg to make the cyborg to be closest possible to human being and produce an immortal cyborg.

[0001]

The present invention relates to a protein made cyborg method-body application immortality device.
[0002]

Traditionally, protein made cyborg method-body application immortality device technology was not.
[0003]

Conventionally, to be achieved through state-of-the-art technology because the protein made cyborg method-body application immortality device technology did not.
[0004]

Body Human Similar behavior plus artificial intelligence by putting the cyborg and fixed that made consciousness energy and of body at Hemishinku technical or right brain right corner gyrus electrodes stimulated protein is assumed to be all.
[0005]

Of immortality with human consciousness body also becomes possible to cyborg close endlessly in human beings.
[0006]

Below, it described in the series logically sentence when the embodiment of the present invention.

First, it is only in conscious energy that was out of body in Hemishinku technology or right brain right corner gyrus electrode stimulation.
It makes a raw material of the protein material in the nitrogen in the air.
Same cyborg body with it and protein human and make their organs and nerves, or the like.
Fixed to Put the consciousness energy that was outside the body removed from the body human in the cyborg.
Artificial intelligence plus body also becomes Cyborg close endlessly in human human similar behavior with the human consciousness of the strongest of immortality in this consciousness energy, it is assumed that it is possible to all.
Protein made cyborg method-body application immortality device 2 is guided by the above as logic.
[0007]

It is carried out as described above.
[0008]

Artificial intelligence also the industrial applicability of the demand of this device in the advance is aging achieved even greater progress cyborg been trying to exceed the human technology is understood to be high.

JP2006055651
FUTURE REJUVENATION DEVICE APPLYING OUT-OF BODY EXPERIENCE OF CONSCIOUSNESS AND BODY SUSPENDED ANIMATION STATE

Inventor:KAJISA ISAO

PROBLEM TO BE SOLVED: To realize immortality by applying out-of body experience of consciousness and a suspended animation state. ;SOLUTION: The out-of body experience of consciousness is carried out by electrode stimulation of right brain right angular gyrus or Hemi-Sync (R) technique to bring the body of a person approaching his/her life into suspended animation state by exposing the body to hydrogen sulfide and repairing the body to rejuvenation by clone technique, or the like, of future science and then returning the external consciousness to the body. Such procedures are repeated to realize the immortality.

[0001]

The present invention relates to a rejuvenation resuscitation to the future in-body awareness and physical state of suspended animation.
[0002]

Conventionally, the right corner gyrus of the electrode stimulation and Hemishinku technology capable of body has been discovered invention was not its application.
(For example, see Non-Patent Document 1.).
Further, although there is a corpse refrigeration technology it was not a state of suspended animation technology.
[0003]

"Ne~icha", September 19, 2002, 270 pages from the 269-page "Nikkei Science" September 2005, 23 pages from 16 pages
[0004]

Traditionally, there was no application of extracorporeal withdrawal and the state of suspended animation technology.

[0005]

Life consciousness that is outside the body withdrawal by returning the consciousness into the body is allowed to resuscitation after you rejuvenation repair the body in cloning technology such as the future of science is in suspended animation by exposing non-lethal dose in the body of hydrogen sulfide before life Matase in vitro me extend.
[0006]

Physically body to return many times that it was resuscitated-body consciousness from the rejuvenated state of suspended animation also made it possible to immortality by repeating.
[0007]

Below, it described in the series logically sentence when the embodiment of the present invention.
Consciousness by electrode stimulation or Hemishinku technology the right corner gyrus of the right cerebral cortex leaves the body.
Using a glass airtight container and exposing the body to hydrogen sulfide in non-lethal amount.
The extent and the rate of reduction of the human body temperature and metabolic rate shows the correlation between hydrogen sulfide concentration in the vessel.
Normally, the suspended animation-like state similar to hibernation in mammals that do not hibernate (human beings included) can be induced by hydrogen sulfide.
And at the same time resuscitation When the human body has been repaired to return the consciousness to the human body.
Life becomes the resuscitation revival can immortality also possible as the human body that have been repaired younger clone technology, etc. by future science in the state of suspended animation in order to extend the close of human life.
[0008]

It is carried out as described above.
[0009]

Western after death in each country, such as dead bodies from the frozen saved as a second method no pain without euthanasia and death with dignity of the baby-boom because it is state of suspended animation without dying not only the methods but rely on future science generation of life INDUSTRIAL APPLICABILITY it is understood that high in Japan.

JP2006021053
EXTERNAL DEPARTURE APPLIED IMMORTALITY APPARATUS

Inventor:KAJISA ISAO

PROBLEM TO BE SOLVED: To provide an apparatus to apply external departure consciousness and to realize immortality. ;SOLUTION: External departure consciousness energy is followed in an 11-dimensional space and regarded and interpreted as graviton. The frequency of a gravitational wave is guided and fixed in a humanoid cyborg with its graviton, allows the same behavior as human beings, and realizes immortality.

[0001]

The present invention relates to immortality that fixed in the cyborg to induce out of body consciousness.
[0002]

Conventionally, the right corner gyrus of the electrode stimulation and Hemishinku technology capable of body has been discovered invention was not its application.
(For example, see Non-Patent Document 1.).
[0003]

"Nature", September 19, 2002, 270 pages from the 269-page "The Lancet" December 15, 2001, 2045 pp. 2039
[0004]

Conventionally, there has been found the invention to be able of body was not immortality technique by applying it.
[0005]

It interpreted mainly to be aware that the graviton energy fraction was out of body together with the graviton the frequency of the gravitational wave is chasing in the gravity wave in 11-dimensional space in which it is going to induce the cyborg can be the same behavior as human beings in it.
[0006]

The physically-body consciousness made it possible to immortality by putting the cyborg.
[0007]

Below, it described in the series logically sentence when the embodiment of the present invention.
Consciousness by electrode stimulation or Hemishinku technology the right corner gyrus of the right cerebral cortex leaves the body.
It is the use of the 11-dimensional cosmology from going Planck scale that was rounded from one-dimensional of the six-dimensional minute it will be interpreted as a graviton that can pass through the six-dimensional from a one-dimensional (graviton).
Subject to further awareness brain waves can be interpreted as a thing that can survive in the flat is the same as the subject to be aware of the graviton from where it is known from the example of the near-death experience.
It is carried out in accordance with the frequency of the graviton and tunes gravitational wave gravity waves can pass through the 11-dimensional universe in to communicate with the graviton of the entity that this consciousness.
Further to realize the awareness of the possible human similar movement to the cyborg by inducing fixed to consciousness for the human type in the cyborg in the gravitational wave immortality.
[0008]

It is carried out as described above.
[0009]

Western postmortem in each country, such as is understood to have high industrial applicability as a second method not only the process but relies on future scientific and stored frozen bodies.

(57) **ABSTRACT**

An energy collection system may collect and use the energy generated by an electric field. Collection fibers are suspended from a support wire system supported by poles. The support wire system is electrically connected to a load by a connecting wire. The collection fibers may be made of any conducting material, but carbon and graphite are preferred. Diodes may be used to restrict the backflow or loss of energy.

ENERGY COLLECTION

CROSS REFERENCE TO RELATED APPLICATIONS

[0001] This application is a continuation in part application of U.S. patent application Ser. No. 12/255,130 filed on Oct. 21, 2008, which is a continuation application of U.S. patent application Ser. No. 11/358,264, filed on Feb. 21, 2006, which are both incorporated by reference herein.

TECHNICAL FIELD

[0002] The present disclosure is generally related to energy and, more particularly, is related to systems and methods for collecting energy.

BACKGROUND

[0003] The concept of fair weather electricity deals with the electric field and the electric current in the atmosphere propagated by the conductivity of the air. Clear, calm air carries an electrical current, which is the return path for thousands of lightening storms simultaneously occurring at any given moment around the earth. For simplicity, this energy may be referred to as static electricity or static energy. FIG. **1** illustrates a weather circuit for returning the current from lightning, for example, back to ground **10**. Weather currents **20**, **30** return the cloud to ground current **40**.

[0004] In a lightening storm, an electrical charge is built up, and electrons arc across a gas, ionizing it and producing the lightening flash. As one of ordinary skill in the art understands, the complete circuit requires a return path for the lightening flash. The atmosphere is the return path for the circuit. The electric field due to the atmospheric return path is relatively weak at any given point because the energy of thousands of electrical storms across the planet are diffused over the atmosphere of the entire Earth during both fair and stormy weather. Other contributing factors to electric current being present in the atmosphere may include cosmic rays penetrating and interacting with the earth's atmosphere, and also the migration of ions, as well as other effects yet to be fully studied.

[0005] Some of the ionization in the lower atmosphere is caused by airborne radioactive substances, primarily radon. In most places of the world, ions are formed at a rate of 5-10 pairs per cubic centimeter per second at sea level. With increasing altitude, cosmic radiation causes the ion production rate to increase. In areas with high radon exhalation from the soil (or building materials), the rate may be much higher.

[0006] Alpha-active materials are primarily responsible for the atmospheric ionization. Each alpha particle (for instance, from a decaying radon atom) will, over its range of some centimeters, create approximately 150,000-200,000 ion pairs.

[0007] While there is a large amount of usable energy available in the atmosphere, a method or apparatus for efficiently collecting that energy has not been forthcoming. Therefore, a heretofore unaddressed need exists in the industry to address the aforementioned deficiencies and inadequacies.

SUMMARY

[0008] Embodiments of the present disclosure provide systems and methods for collecting energy. Briefly described in architecture, one embodiment of the system, among others, can be implemented by a support structure wire elevated above a ground level, at least one collection fiber electrically connected to the support structure wire; a load electrically connected to the support structure wire; and a diode electrically connected between the load and at least one collection fiber.

[0009] Embodiments of the present disclosure can also be viewed as providing methods for collecting energy. In this regard, one embodiment of such a method, among others, can be broadly summarized by the following steps: suspending at least one collection fiber from a support structure wire elevated above ground level, the fiber electrically connected to the support structure wire; providing a load with an electrical connection to the support structure wire to draw current; and providing a diode electrically connected between the collection fiber and the load.

[0010] Other systems, methods, features, and advantages of the present disclosure will be or become apparent to one with skill in the art upon examination of the following drawings and detailed description. It is intended that all such additional systems, methods, features, and advantages be included within this description, be within the scope of the present disclosure, and be protected by the accompanying claims.

BRIEF DESCRIPTION OF THE DRAWINGS

[0011] Many aspects of the disclosure can be better understood with reference to the following drawings. The components in the drawings are not necessarily to scale, emphasis instead being placed upon clearly illustrating the principles of the present disclosure. Moreover, in the drawings, like reference numerals designate corresponding parts throughout the several views.

[0012] FIG. **1** is a circuit diagram of a weather energy circuit.

[0013] FIG. **2** is a perspective view of an exemplary embodiment of many energy collectors elevated above ground by a structure.

[0014] FIG. **2**A is a side view of an energy collection fiber suspended from a support wire.

[0015] FIG. **2**B is a side view of an exemplary embodiment of an energy collection fiber suspended from a support wire and with an additional support member.

[0016] FIG. **2**C is a perspective view of a support structure for multiple energy collection fibers.

[0017] FIG. **2**D is a side view of an exemplary embodiment of a support structure for multiple energy collection fibers.

[0018] FIG. **2**E is a side view of a support structure for an energy collection fiber.

[0019] FIG. **2**F is a side view of an exemplary embodiment of a support structure for an energy collection fiber.

[0020] FIG. **2**G is a side view of a support structure for multiple energy collection fibers.

[0021] FIG. **3** is a circuit diagram of an exemplary embodiment of a circuit for the collection of energy.

[0022] FIG. **4** is a circuit diagram of an exemplary embodiment of a circuit for the collection of energy.

[0023] FIG. **5** is a circuit diagram of an exemplary embodiment of an energy collection circuit for powering a generator and motor.

[0024] FIG. **6** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy and using it for the production of hydrogen and oxygen.

[0025] FIG. **7** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy, and using it for driving a fuel cell.

[0026] FIG. **8** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy.

[0027] FIG. **9** is a flow diagram of an exemplary embodiment of collecting energy with a collection fiber.

[0028] FIG. **10** is a system diagram of an exemplary embodiment of a windmill with energy collectors.

DETAILED DESCRIPTION

[0029] Electric charges on conductors reside entirely on the external surface of the conductors, and tend to concentrate more around sharp points and edges than on flat surfaces. Therefore, an electric field received by a sharp conductive point may be much stronger than a field received by the same charge residing on a large smooth conductive shell. An exemplary embodiment of this disclosure takes advantage of this property, among others, to collect and use the energy generated by an electric field in the atmosphere. Referring to collection system **100** presented in FIG. **2**, at least one collection device **130** may be suspended from a support wire system **120** supported by poles **110**. Collection device **130** may comprise a diode or a collection fiber individually, or the combination of a diode and a collection fiber. Support wire system **120** may be electrically connected to load **150** by connecting wire **140**. Supporting wire system **120** may be any shape or pattern. Also, conducting wire **140** may be one wire or multiple wires. The collection device **130** in the form of a fiber may comprise any conducting or non-conducting material, including carbon, graphite, Teflon, and metal. An exemplary embodiment utilizes carbon or graphite fibers for static electricity collection. Support wire system **120** and connecting wire **140** can be made of any conducting material, including aluminum or steel, but most notably, copper. Teflon may be added to said conductor as well, such as non-limiting examples of a Teflon impregnated wire, a wire with a Teflon coating, or Teflon strips hanging from a wire. Conducting wire **120**, **140**, and **200** may be bare wire, or coated with insulation as a non-limiting example. Wires **120** and **140** are a means of transporting the energy collected by collection device **130**.

[0030] An exemplary embodiment of the collection fibers as collection device **130** includes graphite or carbon fibers. Graphite and carbon fibers, at a microscopic level, can have hundreds of thousands of points. Atmospheric electricity may be attracted to these points. If atmospheric electricity can follow two paths where one is a flat surface and the other is a pointy, conductive surface, the electrical charge will be attracted to the pointy, conductive surface. Generally, the more points that are present, the higher energy that can be gathered. Therefore, carbon, or graphite fibers are examples that demonstrate exemplary collection ability.

[0031] In at least one exemplary embodiment, the height of support wire **120** may be an important factor. The higher that collection device **130** is from ground, the larger the voltage potential between collection device **130** and electrical ground. The electric field may be more than 100 volts per meter under some conditions. When support wire **120** is suspended in the air at a particular altitude, wire **120** will itself collect a very small charge from ambient voltage. When collection device **130** is connected to support wire **120**, collection device **130** becomes energized and transfers the energy to support wire **120**.

[0032] A diode, not shown in FIG. **2**, may be connected in several positions in collection system **100**. A diode is a component that restricts the direction of movement of charge carriers. It allows an electric current to flow in one direction, but essentially blocks it in the opposite direction. A diode can be thought of as the electrical version of a check valve. The diode may be used to prevent the collected energy from discharging into the atmosphere through the collection fiber embodiment of collection device **130**. An exemplary embodiment of the collection device comprises the diode with no collection fiber. A preferred embodiment, however, includes a diode at the connection point of a collection fiber to support system **120** such that the diode is elevated above ground. Multiple diodes may be used between collection device **130** and load **150**. Additionally, in an embodiment with multiple fibers, the diodes restricts energy that may be collected through one fiber from escaping through another fiber.

[0033] Collection device **130** may be connected and arranged in relation to support wire system **120** by many means. Some non-limiting examples are provided in FIGS. **2**A-**2**G using a collection fiber embodiment. FIG. **2**A presents support wire **200** with connecting member **210** for collection device **130**. Connection member **210** may be any conducting material allowing for the flow of electricity from connection device **130** to support wire **200**. Then, as shown in FIG. **2**, the support wire **200** of support system **120** may be electrically connected through conducting wire **140** to load **150**. A plurality of diodes may be placed at any position on the support structure wire. A preferred embodiment places a diode at an elevated position at the connection point between a collection fiber embodiment of collection device **130** and connection member **210**.

[0034] Likewise, FIG. **2**B shows collection fiber **130** electrically connected to support wire **200** and also connected to support member **230**. Support member **230** may be connected to collection fiber **130** on either side. Support member **230** holds the fiber steady on both ends instead of letting it move freely. Support member **230** may be conducting or non-conducting. A plurality of diodes may be placed at any position on the support structure wire. A preferred embodiment places a diode at elevated position at the connection point between collection fiber **130** and support wire **200** or between fiber **130**, support member **230**, and support wire **200**.

[0035] FIG. **2**C presents multiple collection fibers in a squirrel cage arrangement with top and bottom support members. Support structure **250** may be connected to support structure wire **200** by support member **240**. Structure **250** has a top **260** and a bottom **270** and each of the multiple collection fibers **130** are connected on one end to top **260** and on the other end to bottom **270**. A plurality of diodes may be placed at any position on support structure **250**. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support structure wire **200**.

[0036] FIG. **2**D presents another exemplary embodiment of a support structure with support members **275** in an x-shape connected to support structure wire **200** at intersection **278** with collection fibers **130** connected between ends of support members **275**. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**.

[0037] FIG. **2**E provides another exemplary embodiment for supporting collection fiber **130**. Collection fiber **130** may be connected on one side to support member **285**, which may be connected to support structure wire **200** in a first location and on the other side to support member **280**, which may be connected to support structure wire **200** in a second location on support structure wire **200**. The first and second locations may be the same location, or they may be different locations, even on different support wires. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support wire **200**.

[0038] FIG. **2**F presents another exemplary embodiment of a support for a collection fiber. Two support members **290** may support either side of a collection fiber and are connected to support wire **200** in a single point. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**.

[0039] FIG. **2**G provides two supports as provided in FIG. **2**F such that at least two support members **292**, **294** may be connected to support structure wire **200** in multiple locations and collection fibers **130** may be connected between each end of the support structures. Collection fibers **130** may be connected between each end of a single support structure and between multiple support structures. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support structure wire **200**.

[0040] FIG. **3** provides a schematic diagram of storing circuit **300** for storing energy collected by one or more collection devices (**130** from FIG. **2**). Load **150** induces current flow. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. A plurality of diodes may be placed at any position in the circuit. Switch **330** may be electrically connected between load **150** and at least one collection device (**130** from FIG. **2**) to connect and disconnect the load. Capacitor **320** maybe connected in parallel to the switch **330** and load **150** to store energy when switch **330** is open for delivery to load **150** when switch **330** is closed. Rectifier **340** may be electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. Rectifier **340** may be a full-wave or a half-wave rectifier. Rectifier **340** may include a diode electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. The direction of the diode of rectifier **340** is optional.

[0041] In an exemplary embodiment provided in FIG. **4**, storage circuit **400** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **410**. If charging capacitor **410** is not used, then the connection to ground shown at capacitor **410** is eliminated. A plurality of diodes may be placed at any position in the circuit. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. Diode **440** may be placed in series with load **150**. The voltage from capacitor **410** can be used to charge spark gap **420** when it reaches sufficient voltage. Spark gap **420** may comprise one or more spark gaps in parallel. Non-limiting examples of spark gap **420** include mercury-reed switches and mercury-wetted reed switches. When spark gap **420** arcs, energy will arc from one end of the spark gap **420** to the receiving end of the spark gap **420**. The output of spark gap **420** may be electrically connected in series to rectifier **450**. Rectifier **450** may be a full-wave or a half-wave rectifier. Rectifier **450** may include a diode electrically connected in parallel to transformer **430** and load **150**, between the receiving end of spark gap **420** and ground. The direction of the diode of rectifier **450** is optional. The output of rectifier **450** is connected to transformer **430** to drive load **150**.

[0042] FIG. **5** presents motor driver circuit **500**. One or more collection devices (**130** from FIG. **2**) are electrically connected to static electricity motor **510**, which powers generator **520** to drive load **150**. A plurality of diodes may be placed at any position in the circuit. Motor **510** may also be directly connected to load **150** to drive it directly.

[0043] FIG. **6** demonstrates a circuit **600** for producing hydrogen. A plurality of diodes maybe placed at any position in the circuit. One or more collection devices (**130** from FIG. **2**) are electrically connected to primary spark gap **610**, which may be connected to secondary spark gap **640**. Non-limiting examples of spark gaps **610**, **640** include mercury-reed switches and mercury-wetted reed switches. Secondary spark gap **640** may be immersed in water **630** within container **620**. When secondary spark gap **640** immersed in water **630** is energized, spark gap **640** may produce bubbles of hydrogen and oxygen, which may be collected to be used as fuel.

[0044] FIG. **7** presents circuit **700** for driving a fuel cell. A plurality of diodes may be placed at any position in the circuit. Collection devices (**130** from FIG. **2**) provide energy to fuel cell **720** which drives load **150**. Fuel cell **720** may produce hydrogen and oxygen.

[0045] FIG. **8** presents exemplary circuit **800** for the collection of energy. Storage circuit **800** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **810**. If charging capacitor **810** is not used, then the connection to ground shown at capacitor **810** is eliminated. A plurality of diodes may be placed at any position in the circuit. The voltage from capacitor **810** can be used to charge spark gap **820** when it reaches sufficient voltage. Spark gap **820** may comprise one or more spark gaps in parallel or in series. Non-limiting examples of spark gap **820** include mercury-reed switches and mercury-wetted reed switches. When spark gap **820** arcs, energy will arc from one end of spark gap **820** to the receiving end of spark gap **820**. The output of spark gap **820** may be electrically connected in series to rectifier **825**. Rectifier **825** may be a full-wave or a half-wave rectifier. Rectifier **825** may include a diode electrically connected in parallel to inductor **830** and load **150**, between the receiving end of spark gap **820** and ground. The direction of the diode of rectifier **825** is optional. The output of rectifier **825** is connected to inductor **830**. Inductor **830** may be a fixed value inductor or a variable inductor. Capacitor **870** may be placed in parallel with load **150**.

[0046] FIG. **9** presents a flow diagram of a method for collecting energy. In block **910**, one or more collection devices may be suspended from a support structure wire. In block **920**, a load may be electrically connected to the support structure wire to draw current. In block **930** a diode may be electrically connected between the support structure wire and the electrical connection to the load. In block **940**, energy provided to the load may be stored or otherwise utilized.

[0047] A windmill is an engine powered by the energy of wind to produce alternative forms of energy. They may, for example, be implemented as small tower mounted wind engines used to pump water on farms. The modern wind power machines used for generating electricity are more properly called wind turbines. Common applications of windmills are grain milling, water pumping, threshing, and saw mills. Over the ages, windmills have evolved into more sophisticated and efficient wind-powered water pumps and electric power generators. In an example embodiment, as provided in FIG. **10**, windmill tower **1000** of suitable height and/or propeller **1020** of windmill tower **1000** may be equipped with energy collecting fibers **1030**, **1040**. Collecting fibers **1030**, **1040** may turn windmill **1000** into a power producing asset even when there is not enough wind to turn propellers **1020**. During periods when there is enough wind to turn propellers **1020**, collecting fibers **1030**, **1040** may supplement/boost the amount of energy the windmill produces.

[0048] Windmill **1000**, properly equipped with ion collectors **1030**, **1040**, such as non-limiting example carbon fibers, can produce electricity: 1) by virtue of providing altitude to the carbon fiber to harvest ions, and 2) while the propeller is turning, by virtue of wind blowing over the carbon fiber producing electricity, among other reasons, via the triboelectric effect (however, it is also possible for the triboelectric effect to occur, producing electricity, in winds too weak to turn the propeller).

[0049] There are at least two ways that energy collectors may be employed on or in a windmill propeller to harvest energy. Propellers **1020** may be equipped with energy collectors **1030**, **1040** attached to, or supported by, propeller **1020** with wires (or metal embedded in, or on propeller **1020**) electrically connecting energy collectors **1030**, **1040** to a load or power conversion circuit. There may be a requirement to electrically isolate energy collectors **1030**, **1040**, which is added to propeller **1020**, from electrical ground, so that the energy collected does not short to ground through propeller **1020** itself or through support tower **1010**, but rather is conveyed to the load or power conversion circuit. Energy collectors may be connected to the end of propellers **1020** such as collectors **1030**. Alternatively, energy collectors may be connected to the sides of propellers **1020** such as collectors **1040**.

[0050] Alternatively, propeller **1020** may be constructed of carbon fiber or other suitable material, with wires (or the structural metal supporting propeller **1020** may be used) electrically connecting to a load or power conversion circuit. In the case of propeller **1020** itself being constructed of carbon fiber, for example, the fiber may be 'rough finished' in selected areas so that the fiber is "fuzzy." For example, small portions of it may protrude into the air as a means of enhancing collection efficiency. The fuzzy parts of collectors **1030**, **1040** may do much of the collecting. There may be a requirement to electrically isolate carbon fiber propeller **1020** from electrical ground, so that the energy it collects does not short to ground through metal support tower **1010**, but rather is conveyed to the load or power conversion circuit. Diodes may be implemented within the circuit to prevent the backflow of energy, although diodes may not be necessary in some applications.

[0051] In an alternative embodiment, windmill **1000** may be used as a base on which to secure an even higher extension tower to support the energy collectors and/or horizontal supports extending out from tower **1010** to support the energy collectors. Electrical energy may be generated via ion collection due to altitude and also when a breeze or wind blows over the collectors supported by tower **1010**.

[0052] Any process descriptions or blocks in flow charts should be understood as representing modules, segments, or portions of code which include one or more executable instructions for implementing specific logical functions or steps in the process, and alternate implementations are included within the scope of the preferred embodiment of the present disclosure in which functions may be executed out of order from that shown or discussed, including substantially concurrently or in reverse order, depending on the functionality involved, as would be understood by those reasonably skilled in the art of the present disclosure.

[0053] It should be emphasized that the above-described embodiments of the present disclosure, particularly, any "preferred" embodiments, are merely possible examples of implementations, merely set forth for a clear understanding of the principles of the disclosure. Many variations and modifications may be made to the above-described embodiment(s) of the disclosure without departing substantially from the spirit and principles of the disclosure. All such modifications and variations are intended to be included herein within the scope of this disclosure and the present disclosure and protected by the following claims.

Therefore, at least the following is claimed:

1. A method of collecting energy comprising:

suspending at least one collection device with a high density of points per area of the device from a windmill, the at least one collection device electrically connected to the windmill; and

providing a load with an electrical connection to the at least one collection device to draw current.

2. The method of claim **1**, wherein the collection device collects energy by triboelectric effect.

3. The method of claim **1**, wherein the collection device comprises a collection fiber.

4. The method of claim **1**, wherein the collection device comprises a diode and a collection fiber and the diode is electrically connected between the collection fiber and the load.

5. The method of claim **1**, further comprising storing energy provided to the load.

6. The method of claim **5**, wherein storing energy provided to the load comprises storing energy in a capacitor or an inductor.

7. The method of claim **3**, wherein the collection fiber comprises carbon fiber or graphite fiber.

8. A system of energy collection comprising:

a windmill;

at least one collection device with a high density of points per area of the device electrically connected to the windmill; and

a load electrically connected to the at least one collection device.

9. The system of claim **8**, wherein the collection device collects energy by triboelectric effect.

10. The system of claim **8**, wherein the collection device comprises a collection fiber.

11. The system of claim **8**, wherein the collection device comprises a collection fiber and a diode electrically connected between the load and the collection fiber.

12. The system of claim **9**, wherein the diode is elevated relative to the ground level.

13. The system of claim **10**, wherein the collection fiber comprises a carbon fiber or a graphite fiber.

14. The system of claim **8**, further comprising a diode electrically connected between the at least one collection device and the support structure.

15. The system of claim **8**, further comprising: a switch connected in series between the at least one collection device and the load; and a capacitor connected in parallel with the switch and the load.

16. The system of claim **15**, wherein the switch comprises an interrupter connected between the plurality at least one collection device, and wherein the interrupter comprises at least one of a fluorescent tube, a neon bulb, an AC light, and a spark gap.

17. The system of claim **8**, further comprising: a motor for providing power, the motor connected between the at least one collection device and the load; and a generator powered by the motor.

18. The system of claim **8**, further comprising a fuel cell between the support structure and the load.

19. The system of claim **18**, wherein the fuel cell produces hydrogen and oxygen.

20. A system of collecting energy comprising:

means for suspending at least one collection device with a high density of points per area of the device from a windmill structure, the at least one collection device electrically connected to the means for suspending;

means for inducing current flow, the means for inducing current flow electrically connected to the means for suspending; and

means for restricting the backflow of charge carriers, the means for restricting the backflow of charge carriers electrically connected between the at least one collection device and the means for inducing current flow.

IONOSPHERIC BATTERY

Leslie G. Smith, Waltham, Mass., assignor, by mesne assignments, to the United States of America as represented by the Administrator of the National Aeronautics and Space Administration

Filed Mar. 9, 1962, Ser. No. 178,721
11 Claims. (Cl. 310—5)

This invention relates to a method and apparatus for tapping the enormous reservoir of energy existing in the ionosphere and more particularly for furnishing electrical power to space vehicles.

Within recent years various space probes and space vehicles such as satellites have been launched by man in an effort to learn more about the earth and the solar system within which he lives. Each of these various space craft has employed numerous electrical circuits which are utilized to detect and transmit back to earth certain information ascertained by the craft as it moves through space. In view of the presence of such electrical circuits, some source of electrical power must be made available whereby these circuits can be energized. In the past there have been three main sources of electrical power carried by space vehicles for energizing these circuits, namely, (1) conventional storage batteries, (2) solar batteries and (3) a combination of the conventional storage and solar batteries. Although these various electrical power sources have functioned with some degree of success each has certain serious limitations which cannot be readily overcome.

In the first instance, the conventional storage battery may be of either the wet or dry type but, due to its superior storage capacity, the wet cell type is used nearly exclusively in space vehicles. This additional storage capacity of the wet cell battery is of great importance since the useful life of the vehicle is usually dependent upon the proper operation of its electrical circuits which are, in turn, directly dependent upon the capacity and life of the available power source. Use in space vehicles of a storage battery that utilizes a liquid electrolyte presents several problems that have not been completely solved, however, nor is there any apparent solution to some of these problems. For example, to increase the output capacity of the battery and thereby extend the useful life of the satellite a greater amount of electrolyte must be carried by the battery. But to increase the quantity of electrolyte carried by the battery results in both an increase in size and weight of the power source and space vehicle which cannot, in most instances, be tolerated. Furthermore, the electrolyte may not function correctly if it is subjected to the extreme conditions of space such as, for example, the changes in temperature that are normally encountered. Thus, to insure the proper operation of the wet cell battery involved in powering a space vehicle and to prevent any leakage that might occur should the battery be damaged, some shielding or insulating of the battery is usually involved which, needless to say, adds materially to the cost and weight of the vehicle.

To overcome the space, weight and leakage problems encountered when storage batteries of the conventional wet cell type are used, space engineers have turned to the recently developed solar cell or battery which converts the light rays received from the sun directly into electrical energy. While these solar batteries do not require any type of electroylte and are, therefore, relatively light in comparison to the wet cell storage battery, they are expensive and their inherent principle of operation presents one problem which cannot be overcome, namely, the inability of the solar cell to produce power while the space vehicle is shaded from the sun such as occurs when a satellite is in the shadow cast by the earth.

In an effort to overcome this loss of power which occurs each time a satellite passes into the shadow cast by the earth or some other heavenly body, a storage battery of the wet cell type was added to the vehicle. While the satellite is in the sunlight the solar battery powers the various electrical circuits and charges the storage battery so that, once the sunlight is no longer available, the storage battery can be switched on to furnish the necessary electrical power to the vehicle. While this combined system functions satisfactorily, there is added to the already existing problems of weight, size and electrolyte leakage the problem of incorporating a battery charging and switch-over system between the solar and storage batteries. The addition of this type of system to the power source is undesirable since it adds unduly to the complexity, sensitivity and cost of the space vehicle.

According to the present invention, it has been found that some of the foregoing disadvantages of space vehicle power sources can be overcome by employing an ionospheric type battery which utilizes the ionosphere or other ionized medium existing in outer space as a supplemental source of energy. Since power is a scarce commodity essential for the operation of the space vehicle and for the proper functioning of its experiments, any means for supplying additional power while adding only slightly to the weight of the vehicle, increases the efficiency and life of the space vehicle. Although it has been known for some time that the ionosphere contains an enormous reservoir of energy in the form of excited and ionized atoms and molecules, no practical method has heretofore been found whereby this energy could be utilized as a source of power for earth satellites even though much thought has been given to this problem. The operation of the present invention is based upon the discovery that the ionosphere can be utilized as a part of supplemental power source for the load circuit in a space vehicle when said vehicle is equipped with electrodes having different work functions which, in turn, are electrically connected through the load circuit.

Accordingly, a primary object of this invention is to provide a method of producing electrical power from ionized media existing in nature.

Another object of this invention is to provide a simple, highly reliable supplemental power source for space vehicles.

Yet another object of this invention is to provide an ionospheric battery for use by satellites.

Still another object of this invention is to provide an ionospheric battery which utilizes the ionosphere as an electrolyte.

A further object of this invention is to provide a supplemental power source for space vehicles that will operate when shielded from the sun.

Yet a further object of this invention is to provide a power source for a satellite that is light and inexpensive to produce.

Another object of this invention is to provide a satellite with various shaped electrodes constructed of metals having different contact potentials.

These and further objects and advantages of this invention will become more apparent upon reference to the following description, claims and the appended drawings wherein:

FIGURE 1 is a cross sectional view of an orbiting satellite equipped with a power source constructed in accordance with one embodiment of the present invention; and

FIGURE 2 is a view in partial section of an orbiting satellite equipped with a power source constructed in accordance with a second embodiment of the present invention.

With continuing reference to the accompanying drawings wherein like reference numerals designate similar parts throughout the various views, and with initial attention directed to the embodiment of FIGURE 1, reference numeral **10** is used to generally designate a space satellite which is orbiting or otherwise passing through an ionized layer or medium such as, for example, the ionosphere which surrounds the earth. As is well known, the ionosphere contains an enormous number of excited and ionized atoms and molecules which are generated or produced when the gasses surrounding the earth are subjected to bombardment by high energy particles and rays such as, for example, ultra-violet or cosmic rays that originate throughout the solar system. Although these various ionized particles created by this bombardment are invisible to the eye they are represented pictorially by the various dots **12** for purposes of clarity.

The satellite **10** consists of an envelope or outer skin surface **14** which may be constructed of metal, ceramic or any other like material which is suitable for space vehicles of this type. As seen in FIGURE 1, a plurality of electrically conductive electrodes **16–18**, which are shown in the form of rods and are constructed of materials having different contact potentials (work functions), are mounted in a spaced relationship in the medium **12** through apertures **20** in the envelope **14** of the satellite. In order to prevent a leak from occurring between the normally pressurized interior **22** of the satellite and the ionosphere, which is a near vacuum, and to insulate the electrodes in case a metal is used for the envelope **14**, vacuum tight insulator feed-through elements **24** are fitted around the electrodes **16–18** and are securely mounted within the aperture **20**. These feed-through elements may be of any suitable type so long as they are constructed to withstand the changes in environmental conditions encountered in space without losing their insulative and sealing qualities.

Carried within the cavity or interior **22** of the satellite **10** is a load circuit **26** which may be, for example, a transmitter or any other electrical device that requires a source of electrical power for its proper operation. The load circuit **26** is mounted to the interior wall of the satellite by suitable means (not shown) and has its positive and negative power input terminals **28–30** connected to the various electrodes **16–18** respectively, by suitable electrical conductors **32–34**.

The overall principle and operation of the ionospheric battery in relationship to the satellite **10** can be explained substantially in the following manner. While the satellite remains on earth prior to its being hurled into or through an ionized medium, the electrodes **16–18** are at substantially the same potential since very few ionized particles are present. Thus, no current will flow through the load circuit **26**. However, once the satelllite is launched and it enters an ionized medium a potential difference will be established between the electrodes **16–18** and an electrical current will begin to flow through the load circuit **26**. This difference in electrical potential that exists between the electrodes **16–18** while the satellite is in an ionized medium is attributed to the fact that the electrodes **16** are constructed of a material having a different contact potential or work function from that of the electrodes **18**. This difference in contact potential between the electrodes **16–18** will result in the free electrons of the ionized medium being collected on one group of electrodes, for example the electrodes **16**, while the positive ions produced when the gas is ionized will be collected on the other electrodes **18**. With the electrodes **16** charged to a negative potential in relationship to electrodes **18**, a predetermined amount of current will flow through the load circuit **26** and can thus be utilized to power an electrical circuit such as the transmitter mentioned above.

The exact material from which the two types of electrodes **16** and **18** are constructed will depend upon several factors such as, for example, the amount of output power desired, the material readily available for constructing the electrodes, the susceptibility of the material to damage or destruction when exposed to the environmental conditions existing in space, and various other considerations that will be readily apparent to a worker in the battery field.

While the electrodes **16–18** used in the ionospheric battery of FIGURE 1 have been described as rods or whip-like elements it is to be realized that the electrodes may take other shapes. By way of example, a plurality of flat, plate-like electrodes **36–38** are shown mounted on a satellite in FIGURE 2. These electrodes are constructed of materials having different contact potentials and are insulated from the outer surface **14** of the satellite when this is necessary by an insulative layer **40** of any suitable material having the desired insulative properties under the severe conditions existing in space. The use of these plate electrodes **36–38** has the advantage of increasing the surface area exposed to the ionized medium thus permitting a larger output current to be produced without the necessity of using excessively long electrodes as might be the case if the rod electrodes of FIGURE 1 were used.

The output current of the battery is dependent upon the degree to which the medium is ionized and to the extent that the electrode surface area is exposed to the medium. An increase in either results in an increase in the efficiency of the battery. From an analysis of various experiments it is expected that a current of about two microamps per cm.^{2} of electrode surface at a potential of one volt would be produced if the satellite is orbiting in the ionosphere at an altitude of approximately 350 km. and electrodes of gold and platinum are used.

It will also be readily apparent that the envelope of the satellite itself could be constructed in sectional form and of materials having different contact potential thus eliminating the necessity of attaching different electrodes to the satellite or the slight increase in weight necessarily involved. Of course the various sections of material making up the envelope of the satellite would have to be insulated from one another to prevent electrical shorting from occurring.

It will be apparent from the foregoing that the power source of this invention is extremely light, rugged and involves a minimum of cost to construct. By using the vast natural reservoir of energy existing in the form of ionized gases for producing the electrical power necessary to energize the various electrical circuits of a space vehicle a practically indefinite source of electrical power is made available to the vehicle. An ionospheric battery constructed in accordance with this invention is also much more reliable in operation than other heretofore known power sources since no liquid electrolyte is involved which can leak, deteriorate or otherwise become spent, nor is the operation of the battery dependent upon its position in relationship to a source of light.

The invention may be embodied in other specific forms without departing from the spirit or essential characteristics thereof. The present embodiments are therefore to be considered in all respect as illustrative and not restrictive, the scope of the invention being indicated by the appended claims rather than by the foregoing description, and all changes which come within the meaning and range of equivalency of the claims are therefore intended to be embraced therein.

What is claimed and desired to be secured by United States Letters Patent is:

1. A space vehicle equipped with a generator of electrical energy operable in the ionosphere as a supplemental source of potential for a load thereof, said generator comprising at least two electrode means on said vehicle and positioned to contact said ionosphere when said vehicle is in said ionosphere, said two electrode means each having different contact potentials, one of said two electrode means being gold and the other being

platinum, and electrical connector means connecting said two electrode means to said load.

2. Apparatus for generating electrical energy from the ionosphere comprising, a pair of spaced electrode means having different contact potentials positioned to contact said ionosphere so that a direct-current electric potential is established between said electrode means, load circuit means, and means electrically connecting said load circuit means to said electrode means whereby said load circuit means is powered by the direct-current electrical potential existing between said electrodes.

3. Apparatus for generating electrical energy from the ionosphere comprising, carrier means, a first electrode having a first contact potential mounted on said carrier means, a second electrode having a second contact potential spaced from said first electrode and mounted on said carrier means, said first and second electrodes being positioned on said carrier means so that they will be in contact with said ionosphere when said apparatus is placed in the ionosphere so that a direct-current electric potential is established between said first and second electrodes, and an electrical load circuit connected between said first and second electrodes, said load circuit being powered by the direct-current potential produced by said first and second electrodes.

4. Apparatus according to claim 3 wherein said first and second electrodes extend away from said carrier means.

5. Apparatus according to claim 3 wherein said first and second electrodes form a portion of said carrier means.

6. In a space vehicle adapted to pass through ionized areas in space, a power source for said vehicle while it is passing through said ionized areas comprising, a plurality of electrode means located on the outer surface of said vehicle, said electrode means being constructed of materials having different contact potentials, and means connecting said electrode means together through a load circuit whereby said circuit receives a source of direct-current as said space vehicle passes through said ionized areas.

7. In a space vehicle according to claim 6 wherein said electrode means are rod shaped.

8. In a space vehicle according to claim 6 wherein said electrode means are plate shaped.

9. A satellite comprising an envelope, electrical load means carried in said envelope, apertures extending through said envelope at spaced points, electrode means having different contact potentials, said electrode means passing through said apertures, means in said aperture for insulating said electrode means from said envelope, and electrical conductor means connected between said electrode means and said electrical load means whereby said electrical load means is energized by the direct-current electric potential established when said electrode means passes through an ionized medium.

10. A space satellite comprising an envelope, an electrical load circuit carried in said envelope, a power supply for said electrical load circuit comprising a first electrode having a first contact potential connected to said electrical load circuit and extending through said envelope and a second electrode having a second contact potential connected to said electrical load circuit and extending through said envelope, said first and second electrodes being insulated from one another so that said electrical load circuit is powered by the direct-current electric potential established by said first and second electrodes coming in contact with an ionized medium.

11. The method of powering electrical circuit means carried by a space vehicle comprising the steps of positioning first and second electrode means having different work functions on said vehicle, passing said vehicle through the ionosphere so that said first and second electrode means are in contact therewith and produce a direct-current potential between them, and connecting said first and second electrodes to said electrical circuit means by means of electrical connector means, whereby said direct-current potential is made available for operating said circuit.

ION COLLECTOR FOR MASS SPECTROMETRY

Donald G. Tipotsch, Fullerton, Calif., assignor to Beckman Instruments, Inc., Fullerton, Calif., a corporation of California

Application March 26, 1956, Serial No. 573,874

5 Claims. (Cl. 250—41.9)

The present invention relates in general to mass spectrometry and, more particularly, to an ion collector for radio frequency mass spectrometers, which may, for example, be of the type disclosed and claimed in the copending applications of George H. Hare and David R. Margetts, Serial No. 370,582, filed July 27, 1953, and Serial No. 378,756, filed September 8, 1953, now U.S. Patent 2,769,093 granted October 30, 1956.

As general background, mass spectrometers of this general type include: an ion source; ion analyzer means for selectively varying the kinetic energies of the ions emitted by the source in accordance with their respective masses, or more accurately, in accordance with their respective charge-to-mass ratios; and selective ion collector means. The analyzer provides selected ions of a selected charge-to-mass ratio with an optimum kinetic energy level while providing nonselected ions of other charge-to-mass ratios with other kinetic energy levels differing from the optimum. The ion collector separates the selected ions from the non selected ions on the basis of the energy level differences produced by the analyzer means, the ion collector providing a collecting electrode, or collecting electrode means, for collecting the selected ions. The optimum kinetic energy level with which the selected or preferred ions are provided may be either a maximum or a minimum, the ion collector of the present invention having particular utility with an instrument which maximizes the kinetic energy of the preferred ions, although it is useful also with one which minimizes the kinetic energy thereof. Further, while the ion collector of the invention is particularly applicable to a radio frequency mass spectrometer, and is considered with particular reference to a radio frequency instrument herein, it will be understood that it may be utilized in any instrument which selectively alters the kinetic energy level of ions of a preferred mass, or preferred mass-to-charge ratio, relative to nonpreferred ions of other charge-to-mass ratios.

Basically, the operation of an ion collector of the type to which the present invention relates involves projecting the ion beam emerging from the analyzer means into a substantially uniform electrostatic deflecting field at an angle of substantially 45° to the equipotential planes of such field and at an initial position in a plane of low field potential so that the ions traverse planes of successively higher field potentials. The ions constituting the beam accordingly execute parabolic trajectories within the deflecting field space varying in altitude and range in accordance with the respective entrant kinetic energies thereof. An ion having a high entrant energy level tends to attain both a higher altitude and a greater range than one of low entrant energy. This variation in trajectory makes it possible to separate ions having a selected entrant kinetic energy from those ions having different entrant kinetic energies, the selected entrant energy level corresponding to the preferred charge-to-mass ratio.

In the ion collectors of this general character which are described in the aforementioned copending applications, the ions are separated on the basis of the maximum or peak altitudes they attain in the electrostatic deflecting field. For example, in one prior ion collector, used in an instrument which imparts the maximum energy level to the selected ions, these ions are collected at the crest of their parabolic trajectory by means of a collecting electrode which intercepts only the ions attaining the highest peak altitude, but which does not intercept ions having lower maximum or peak altitudes. On the other hand, if the analyzer means of the instrument is such that it imparts the minimum energy to the selected ions, an electrode is provided in the region of maximum trajectory altitude for intercepting all ions attaining higher altitudes than that of the selected ions, the latter attaining only a minimum peak altitude and clearing the mentioned intercepting electrode to impinge on a separate, collecting electrode.

The foregoing prior ion collectors take advantage of a focusing action which causes parallel, equal-energy rays of the ion beam to converge within a narrow band at the crest of the trajectory. The lateral separation of such parallel rays results from the finite width of the ion entrance aperture through which ions are admitted into the electrostatic deflecting field. However, it has been found that while this focusing action compensates effectively for lateral displacements of the selected ions in the ion beam, it does not compensate for slight deviations in the angle at which the selected ions, or any single-energy ions, enter the deflecting field. In fact, the effect of such entrant angle deviations on resolution, and on the useful ion current obtainable at the collecting electrode, may be much more serious than the effect of lateral spacing due to the width of the entrance aperture. Thus, in an instrument wherein the maximum energy is imparted to the selected ions, it is possible for ions of lower energy than that of the preferred ions to impinge on the collecting electrode if they enter the field at an angle of less than 45° with respect to a line perpendicular to the equipotential planes of the field. Similarly, in an instrument which imparts the minimum energy to the preferred ions, ions of an energy higher than the selected ions, but entering the deflecting field at an angle of more than 45°, may miss the intercepting electrode adapted to block the nonpreferred ions and may impinge together with the preferred ions on the collecting electrode. In either event, mass resolution is seriously impaired. In some instances (in instruments wherein selected ions attain maximum energy) it has been necessary in order to fully resolve adjoining masses above mass 40, for example, to reduce the deflecting potential and accept only the 10% of the available ions of the selected mass which attain the maximum trajectory altitude and which are free from interfering ions of the adjoining mass. Obviously, this drastically reduces the ion current available at the collecting electrode.

Another disadvantage of prior ion collectors which operate on the basis of ion trajectory altitudes is that when a mass spectrum is scanned, i.e., when the instrument is made responsive to successive masses as by varying the resonant frequency in radio frequency instruments, the ions of successive masses may enter the ion collector at a continuously varying angle, the reasons for this phenomenon being only incompletely understood at the present time. Thus, when collecting on the basis of variations in trajectory altitude with ion mass, the proportion of the preferred ion beam collected varies somewhat with mass. This would not be objectionable except for the fact that it is desirable to vary the deflecting potential in order to change the resolution, e.g., in order to collect a larger portion of the available current where the mass resolution is inherently high, as at low mass numbers. When this is done, it is found that the fractionating pattern, or distribution of ion fragments of various masses for a given simple molecule, changes also. For maximum operating convenience however, this should remain independent of resolution.

A primary object of the present invention is to eliminate the foregoing and various other disadvantages of prior ion collectors, irrespective of the type of mass spectrometer with which the ion collector of the invention is used.

More particularly, an important object of the present invention is to provide an ion collector which separates the selected ions from the nonselected ions on the basis of the differences in the range of the trajectories which the ions execute, instead of on the basis of the differences in the altitudes thereof.

In other words, an important object of the present invention is to separate the selected and non-selected ions at the ends of their trajectories within the deflection space, instead of at the crests thereof. As will be shown hereinafter, variations in trajectory range with variations in entrant angle are much smaller than variations in trajectory altitude with such angular variations. This permits the ion collector of the invention to achieve superior resolution and increased ion current, these being important features of the invention.

Another object of the invention is to provide an ion collector which includes electrode means defining a substantially uniform electrostatic deflecting field, means for admitting ions into such field in a beam at a mean inclination of substantially 45° to the equipotential planes of the field and at an initial position in a plane of low potential, whereby ions of different masses execute different trajectory ranges in returning to terminal positions in a plane of substantially the same low field potential, means adjacent the terminal position of the trajectory range executed by the selected ions for intercepting ions deviating therefrom in range by more than a predetermined small amount, and collecting electrode means adjacent such intercepting means for collecting selected ions which are not intercepted by the intercepting means.

A further object is to provide an ion collector which includes two spaced, parallel electrodes disposed at an angle of substantially 45° to the ion beam, one of these electrodes being maintained at a lower potential than the other to provide a substantially uniform electrostatic deflecting field therebetween. A related object is to provide the lower-potential electrode with an ion entrance aperture and to provide it with an ion intercepting edge spaced from the ion entrance aperture, such ion intercepting edge preferably being formed as an edge of an ion exit aperture. Still another object is to provide an ion collecting electrode external to the space between the deflecting electrodes and so positioned with respect to the ion exit aperture that ions not intercepted by the ion intercepting edge of such deflecting electrode impinge on the collecting electrode as a beam of substantially selected ions only.

The foregoing objects, advantages, features and new results of the present invention, together with various other objects, advantages, features and new results thereof which will be evident to those skilled in this art in the light of the present disclosure, may be attained with the exemplary embodiment of the invention illustrated in the accompanying drawings and described in detail hereinafter. Referring to the drawings:

Fig. 1 is a semidiagrammatic, longitudinal sectional view of a mass spectrometer which incorporates the ion collector of the invention;

Fig. 2 is a graph comparing variations in ion trajectory altitude and ion trajectory range with variations in entrant angle into an electrostatic deflecting field;

Fig. 3 is a graph illustrating the distribution of ion current density in the region of the ion trajectory peaks in the electrostatic deflecting field; and

Fig. 4 is a graph illustrating the variation in ion current density near the position of maximum ion trajectory range in the electrostatic deflecting field.

An instrument 9 embodying an ion collector 10 of the present invention is illustrated in Fig. 1 of the drawing, this instrument being similar in principle to that described in said applicaton Ser. No. 370,582. The means for ionizing the sample, for imparting different energies to the ions of different mass, and for collecting a selected ion species are enclosed in a vacuum-tight housing 11 connected to a vacuum pumping system, not shown, via a duct 12. More specifically, the sample, in the form of a gas or vapor, is introduced into an ion chamber 14 at a suitable pressure through an inlet tube 13. A filament 15 powered by a transformer 15*a* provides an electron stream 16 which is directed through the ion chamber 14 and collected by a positively charged electrode 17. A portion of the sample material is ionized under bombardment by the electron stream. Two sets of perforated electrodes, 19 to 21, and 22 to 24, connected to points of suitable potential on a power supply 32′, draw the ions out of the ion chamber, giving them an initial acceleration and collimating them into a narrow beam 18. The perforations in these and all subsequent electrodes may either be holes or, preferably, elongated slits. Thus, Fig. 1 may be interpreted as showing slits which are oriented perpendicularly to the plane of the drawing. In this case, however, it would be preferable to reorient the electron beam so that it too is perpendicular to the plane of the drawing.

The ion chamber 14, the electron beam forming means 15, 17 and the electrodes 19 to 24 constitute what may be termed the ion source. This is followed by a so-called analyzer means or analyzer section which comprises an array of perforated plates, 25, 25*a*, . . . 25*n*, connected alternately to one terminal of a variable radio frequency oscillator 27′ and an oscillator return point. e.g., ground, as shown. For a given accelerating potential at the ion source, and any given frequency and amplitude of the radio frequency oscillator 27′, only particles of a particular mass, or, strictly speaking, of a particular charge-to-mass ratio, will pass through the analyzer plates in resonance with the radio frequency signal. Ions of this selected mass are accelerated in phase with the alternating voltage through each of the successive analyzer stages and thus acquire a maximum kinetic energy, whereas particles of different mass, higher or lower, fall out of phase and either do not emerge from the analyzer section or, at best, emerge with energies less than that of the preferred particle.

The ion collector 10 of the invention comprises two parallel electrodes or plates 26 and 27 inclined at an angle of substantially 45° to the entrant ion beam 18. The base plate 26 is at a low potential, for example, ground, and may be connected to the last analyzer plate 25*n* as shown. The plate 27 is at a relatively high potential, e.g., about one-half the ion beam energy in electron volts, or about 500 volts. Thus, there is provided between the plates 26 and 27 a substantially uniform electrostatic field having a plane of minimum field potential at the base plate 26. The ions from the analyzer section enter the space between the plates 26 and 27 through a relatively narrow entrance slit 28 in the plate 26, each ion traversing a parabolic trajectory and returning to the base plate 26, where ions of the predetermined charge-to-mass ratio pass through an ion-selective exit slit 29 in the plate 26 positioned at the point of maximum range. Particles traversing the slit 29 impinge on a collecting electrode or electrode means 30 at or near ground potential. Ions of lower or higher mass, and therefore of lower energy, fall short of the slit 29 and impinge on an ion intercepting means formed by the base plate 26 adjacent an edge 29*a* of the slit 29. The numerals 32 and 33 represent, respectively, the paths of preferred and nonpreferred ions. An indicating and/or recording means 31, connected to the electrode 30, indicates and/or records the relative abundance of the selected ions.

The ion collector 10 operates on the principle that, for ions of any given energy, those which enter at 45° attain the maximum range. Particles of the same given energy, but of an initial entrant angle either larger or smaller than 45°, return to the base plate **26** within a shorter distance. However, the variation in range, for varying entrant angle, is extremely small compared with the corresponding variation in the maximum attained altitude. Accordingly, by collecting at the position of maximum range, the overlapping of the paths of ions of adjacent masses due to deviations in the entrant angle, when more than one ion species enters the collector, is greatly reduced and resolution and useful ion current are corrpesondingly increased.

The foregoing principle is illustrated in Fig. 2. The origin, lower left, corresponds to a point on the entrance slit **28**, and the base line $y=0$ corresponds to the surface of the base plate **26**. The curve a is the trajectory of a particle entering at $\alpha=45°$, and the curves b and c are the trajectories for particles of the same energy deviating in either direction by 0.1 radian, or about 5.7°. This is a relatively large angular deviation and is shown for purposes of illustration only. Taking the peak trajectory value of y for $\alpha=45°$ as unity, the range, or maximum value of x, is 4. For particles entrant at any angle α,

$$x=v_o t \sin \alpha,$$

and

$$y=\tfrac{1}{2} at^2+v_o t \cos \alpha,$$

where v_o is the entrant velocity, t is time and a is the acceleration, a being equal to $-Ee/m$ where E is the deflecting field strength, and e/m the ionic charge-to-mass ratio.

Eliminating t, expressing a in terms of the deflection field and v_o in terms of the effective total voltage V accelerating the ion before entering the collector **10**, the following equation results:

$$y=\frac{-Ex^2}{4V \sin^2 \alpha}+\frac{x}{\tan \alpha}$$

It is found that y has a maximum value, or altitude, at the peak of the trajectory given by

$$y_{\max}=\frac{V \cos^2 \alpha}{E}$$

and that $x_{\max}$, or maximum range, is

$$x_{\max}=\frac{4V}{E} \sin \alpha \cos \alpha$$

The trajectory for a value of α less than 45° crosses the trajectory for $\alpha=45°$ at a value of x given by

$$x_c=\frac{-4V}{E}\left(\frac{\cos \alpha-\sin \alpha}{2 \sin \alpha-\csc \alpha}\right)$$

The incremental changes of maximum altitude and range with change of initial angle are respectively given by

$$\frac{dy_{\max}}{d\alpha}=\frac{-V}{E} \sin 2\alpha$$

and

$$\frac{dx_{\max}}{d\alpha}=\frac{4V}{E} \cos 2\alpha$$

It is noted that at $\alpha=45°$, $dx_{\max}/d\alpha$ is zero, i.e., x is a maximum, and that for even relatively large deviations from $\alpha=45°$, only very small changes in $x_{\max}$ may be expected. On the other hand, $dy_{\max}/d\alpha$ has a finite value at $\alpha=45°$, and for given deviations of α, the deviaation in $y_{\max}$ may be many time that of $x_{\max}$. This is borne out in Fig. 2, where, for the entrant angle deviation of ±0.1 radian, the total deviation in $y_{\max}$ is 0.396, and the total deviation of $x_{\max}$ is only 0.08, a ratio of approximately five to one. Taking smaller angles of deviation, closer to those encountered in practice, the ratio of the total deviation of $y_{\max}$ to that of $x_{\max}$ is rapidly increased. Thus, at a deviation of ±1°, total deviations in $y_{\max}$ and $x_{\max}$ are 0.068 and 0.0024, respectively, a ratio of approximately 28 to 1.

It will be noted that for any pair of rays deviating in entrant angle symmetrically from 45°, the deviation in $y_{\max}$ is symmetrical, and the range, or $x_{\max}$, values are identical. Thus the curves b and c of Fig. 2 have a common terminus on the x axis.

Other conditions being equal, the collector **10** of the present invention makes possible, in a typical instrument of the type described, an increase in the ion signal current by a factor of five or more, or for the same current, a substantial increase in resolving power. The reason for the current gain is explained by the schematic curves of Figs. 3 and 4. In Fig. 3, the curves m_1 and m_2 show the ion current density distribution, attributable to each of two adjoining masses, along the "vertical" or y direction, in the vicinity of the trajectory peaks, where prior ion collectors have operated. The preferred mass is represented by m_1 and, for simplification, the relative total abundance of the masses is assumed equal. The long "skirts" on these curves are largely the effect of ions entering the deflection space at angles which deviate in either direction from 45°. To obtain a signal for the ion m_1 which is substantially independent of the ion m_2, only that portion of the m_1 current may be collected which falls to the right of the dotted line and is indicated by the shaded area. Thus, because the right-hand skirt of m_2 overlaps a major portion of the range of m_1, only a small portion of m_1 may be collected to give a useful signal.

Fig. 4 shows the improvement achieved in the present invention by collecting in the region of maximum range. Since the distribution for each ion species tails off primarily in one direction only, i.e., to the left as shown in this figure, a much larger portion of the available current of the preferred ion, again shown by the shaded area, may be collected without interference by the adjoining ion. The leading (right-hand) edges of the curves of Fig. 4 are not perfectly vertical because particles of a given mass entering the collector **10** at 45° vary slightly in energy, and because of the particular shape of the energy distribution curve for such particles.

The effect of the invention is that aberration due to angular deviation is no longer a dominant factor in restricting attainable resolution or ion current. Instead, this effect is made at least comparable to, and usually smaller than, other effects which limit performance, such as energy separation of adjacent mass peaks, energy spread for a given mass, collector slit-width effects, etc.

Referring again to Fig. 1, it will be seen that additional advantages result from the fact that the collecting or sensing electrode **30** is now adjacent the deflection plate, **26**, which is at the lower potential, i.e., at or near ground potential, rather than near the high voltage plate **27**. For example, transients formerly appearing when the deflection voltage was changed, due to capacitive coupling between the deflector plate and the sensing electrode, are substantially eliminated. The fractionating pattern becomes substantially independent of the deflection voltage, because of the relative insensitivity to variations in the entrant angle. Moreover, the electrostatic deflection field in the vicinity of the sensing electrode **30** is now substantially free of distortion, and this further improves resolution. Additionally, the problem of electrical leakage between the relatively high-potential deflection electrode and the low-potential sensing electrode is substantially eliminated, since the sensing electrode now adjoins the deflection plate of lower potential. Finally, the lower potential deflection plate **26** may, if desired, be made about 20 volts negative with respect to the collector electrode **30**. This permits the plate **26** to act as a suppressor for secondary electrons originating at the collector electrode **30** by returning them to this electrode.

Because the present invention increases the ion current available at the sensing electrode, it is possible, if desired, to reduce the width of the entrance slit **28** appreciably, and thereby reduce the lateral spread in initial ion position. A suitable entrance slit width may be 0.015 inch. The collector or exit slit **29** is made somewhat larger, e.g., 0.040 inch, so that the beam of preferred ions may still impinge on the collector electrode **30** despite any residual angular deviation effect and the small energy spread for preferred ions entering at 45°. The resolution, in general, of the collector **10** is a function of the ratio of the entrance slit width to the distance between the slits **28** and **29**.

It will be apparent that the significant functional portion of the exit slit **29** is the inner edge **29*a*** thereof. For example, the base plate **26** could terminate at **29*a***, and the outer edge, **29*b***, of the slit could be omitted. In general, however, it is desirable to use an actual slit and thereby maintain a more nearly undisturbed deflection field in the exit slit region.

It will be apparent also that in a mass spectrometer where the analyzer section decelerates the selected ions instead of accelerating them, the collector of the invention may also be useful in certain cases. The exit slit or exit slit edge of the collector in this case is positioned to select ions of minimum, rather than maximum, energy.

Although I have disclosed an exemplary embodiment of my invention herein for purposes of illustration, it will be understood that various changes, modifications and substitutions may be incorporated in such embodiment without departing from the spirit of the invention as defined by the claims hereinafter appearing.

I claim as my invention:

1. In an ion collector for an ion sorting device comprising an ion source and analyzer means for imparting maximum energy to selected ions of a particular charge-to-mass ratio emitted from said source relative to non-selected ions emitted therefrom; the combination of: means providing a substantially uniform electrostatic deflecting field; means for admitting a beam of ions from said analyzer means to said field at a mean inclination of substantially 45° to the equipotential planes of said field and at an initial position in a plane of low field potential, the ions of said beam executing varying trajectories in said field and returning to terminal positions in a plane of substantially the same low field potential, said selected ions attaining a particular, maximum range greater than the range executed by said non-selected ions; means adjacent the terminal position of said maximum range for intercepting ions executing ranges shorter than said maximum by more than a predetermined small amount; and collecting electrode means adjacent said intercepting means for collecting substantially only said selected ions.

2. An ion collector as defined in claim 1 wherein said means providing said deflecting field comprises a pair of spaced, parallel electrodes and means for maintaining said electrodes at different electrode potentials, respectively, said ion admitting means including an ion entrance aperture in that electrode of said electrode pair which is at the lower of said electrode potentials.

3. An ion collector as defined in claim 2 wherein said ion intercepting means comprises an ion intercepting edge of said lower-potential electrode.

4. An ion collector as defined in claim 3 wherein said ion intercepting edge comprises an edge of an ion exit aperture located in said lower-potential electrode and spaced from said ion entrance aperture.

5. An ion collector as defined in claim 4 wherein said collecting electrode means is located external to the space defined by said electrodes and adjacent to said ion exit aperture.

This causes electrical current to flow, driven by the atmospheric voltage, so that power is generated at the ground. The rate of this current is governed by complex physics in the boundary layer of the collector material, doubtless because of its very high surface area. Ionization can occur on this collector at extremely low voltages because of the sharp, needle-like protrusions on its surface. This understanding of the physics suggests that power generation can be scaled as surface area

Ion Power works as shown in the following diagram. The voltage source behind this power system is the Earth's global electric circuit. The Ion Collectors are positioned in the atmosphere to couple with the high voltage, pulling current to a lower voltage where it does electrical work through the electrical power grid. This report will first discuss how it works, then how it can be scaled up to industrial application, and then the economic viability of this power source.

How Ion Power Works

The Ion Power Group has performed tests at its facility in north Florida, successfully demonstrating the critical function of the technology application using their patented, carbon-based ion collector material, thereby achieving Technology Readiness Level 3 (TRL-3). In some of these tests, 400 ion collectors were

Click for Full Report

times voltage. This was incorporated into a simulation of the solar cycle with random storms, and power generation of photovoltaics (PV) and Ion Power were simulated as feeding into a smart grid. Because Ion Power collects the most energy at complementary times compared to PV, the energy storage requirements on the smart grid is greatly reduced. This causes the cost of electricity also to be greatly reduced compared to photovoltaics alone, resulting in energy costs for the overall smart grid of about 8.25 cents per kWh, which is less expensive than any other energy source other than some wind farms (which are only slightly less expensive and have limited geographic applicability). This analysis uses extremely conservative assumptions, so actual energy costs may be much less. **The estimated value to the US economy is between $62 billion and $150 billion (annually)** with proportionately large value to the global economy.

Ion collectors can be composed of carbon/graphite/graphene, while not metallic, are electrically conductive, flexible and durable. Electric fields are known to coalesce at conductive points known as the "Corona Effect". The solution of Poisson's equation to determine electric field intensity around the collectors shows us that the highest electric fields will be around sharp points; the sharper the point, the greater the electric field. Ion collectors offer millions of microscopic electrically conductive points

TOP

and protrusions which readily couple to the electric fields of near-Earth ions transferring high-voltage electricity from the atmospheric ions to the ion collectors.

$$\nabla^2\varphi = -\frac{\rho}{\varepsilon}.$$

Ground based circuitry maintains the ion collector material at a voltage considerably lower than the surrounding atmospheric ions thereby employing the electrostatic attraction principle causing nearby ions to migrate to the ion collectors. High voltage wire connected to the ion collectors convey the harvested high voltage DC electricity to a storage medium or electrical load to produce work. Measurements have shown that ion collectors made of graphite are more efficient at harvesting electricity from airborne ions than all other tested metals. In some tests, by as much as 55x greater efficiency. Some of the tested metals include highly conductive silver, copper, and aluminum wire – aluminum spheres – copper and aluminum sheets.

The below graphs show voltage and current coupling characteristics comparing metal in one test (indicated as red and green) to carbon/graphite (indicated as purple).
